jobobit pbs.HOOK_EVENT_JOBOBIT	Triggered when server receives job or subjob obit	At server	See section 6.3.1.7, "jobobit: Event when Server Receives Job or Subjob Obit", on page 97.
resv_begin pbs.HOOK_EVENT_RESV_BEGIN pbs.RESV_BEGIN (**deprecated**)	A resv_begin hook runs when a reservation begins.	At server	See section 6.3.1.11, "resv_begin: Event when Reservation Starts", on page 100.

Table 6-25: Event Types and Objects

Event Type & Constant Object	Trigger	Where Run	Description
resv_confirm pbs.HOOK_EVENT_RESV_CONFIRM pbs.RESV_CONFIRM (**deprecated**)	A resv_confirm hook is executed when a reservation is confirmed or reconfirmed	At server	See section 6.3.1.9, "resv_confirm: Event when Reservation is Confirmed", on page 99.
modifyresv pbs.HOOK_EVENT_MODIFYRESV pbs.MODIFYRESV (**deprecated**)	Triggered by `pbs_ralter` and the `pbs_modify_resv` API call. A modifyresv hook runs when a reservation is altered.	At server	See section 6.3.1.10, "modifyresv: Event when Reservation is Altered", on page 99.
postqueuejob pbs.POSTQUEUEJOB	Triggered by `qsub` and the `pbs_submit()` API call. Not triggered by requeueing a job (`qrerun`) or on node_fail_requeue, when a job is discarded by the MoM because the execution host went down. A postqueuejob hook is executed after the job is queued; the job already has new queue and/or server values when this hook runs.	At server	See section 6.3.1.3, "postqueuejob: Event after Job is Queued", on page 93.

6.3.1.1 Getting Human-readable Names for Hook Event Types

Each hook event type corresponds to a human-readable string. For example, 8388608 corresponds to "HOOK_EVENT_JOBOBIT". The pbs.REVERSE_HOOK_EVENT object is a Python dictionary of event types mapped to human-readable names. This is useful for logging events. The type for an event is found in pbs.event.type.

6.3.1.1.i Syntax

<string> = pbs.REVERSE_HOOK_EVENT[<event type>]

For example:

```
my_event_type_str = pbs.REVERSE_HOOK_EVENT[my_event.type]
```

or

<string> = pbs.REVERSE_HOOK_EVENT[pbs.<event type>]

For example:

```
my_event_type_str = pbs.REVERSE_HOOK_EVENT[pbs.HOOK_EVENT_QUEUEJOB]
```

6.3.1.1.ii Example

Example 6-1: Printing a human-readable name for a pbs.HOOK_EVENT_QUEUEJOB event type using the type:

If the event is `my_event` and the event is of type pbs.HOOK_EVENT_QUEUEJOB:

```
print(pbs.REVERSE_HOOK_EVENT[my_event.type])
```

results in:

```
HOOK_EVENT_QUEUEJOB
```

6.3.1.2 queuejob: Event when Job is Queued

6.3.1.2.i Modifying Job Submission (qsub)

- When a job is submitted via qsub, queuejob hooks can modify the following things explicitly specified in the job submission:
  - Job attributes that can be set via qsub
  - Job comment
  - Resources requested by the job
- When a job is submitted via qsub, queuejob hooks can add resource requests to those specified in the job submission
- The input job attributes on which queuejob hooks operate are those that exist after all qsub processing is completed. These input attributes include:
  - Command line arguments
  - Script directives
  - Server default_qsub_arguments
- When a queuejob hook runs at job submission, the hook can affect only that job.
- A queuejob hook runs once per subjob.
- For queuejob hooks, the input job attributes do not include:
  - Server or queue resources_default or default_chunk.
  - Conversions from old syntax (-lnodes or -lncpus) to new select and place syntax

See section 5.2.4, "Using Attributes and Resources in Hooks", on page 45, for a complete listing of attributes and resources that this hook can modify.

6.3.1.2.ii The queuejob Hook Interface

The event type for this event is pbs.HOOK_EVENT_QUEUEJOB.

A queuejob hook runs after all processing of qsub input, just before the job reaches the server, and before the job is queued, including when a job is peer queued to a server that has a queuejob hook. (See Figure 4-6.) The hook is triggered by qsub or the pbs_submit() API call. A queuejob hook is not triggered by requeueing a job (qrerun) or on node_fail_requeue, when a job is discarded by the MoM because the execution host went down. A queuejob hook runs once per job array.

In a queuejob event, the event's job object members are as they would be if the job were to be successfully submitted.

A pbs.HOOK_EVENT_QUEUEJOB event has the following member, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().job

A pbs.job object with the attributes and resources specified at submission for the job being queued. See section 6.6, "Job Objects", on page 132.

A pbs.HOOK_EVENT_QUEUEJOB event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

A pbs.event().accept() terminates hook execution and allows the job to be queued, and any changes to job attributes or resources take effect.

A pbs.event().reject() terminates hook execution and causes the job not to be queued. The job is not accepted by the server, and is not assigned a job ID.

6.3.1.2.iii Caveats for queuejob Hook

If a user submits a job using old `-lnodes` or `-lncpus` syntax, this is translated to a select statement, but only after a queuejob hook has run. The queuejob hook does have access to the job's resource request.

6.3.1.3 postqueuejob: Event after Job is Queued

6.3.1.3.i Calculating Budget Required to Run Job

After a job is queued, postqueuejob hooks can use the updated job information to e.g. calculate the budget required to run the job. The hook can affect only that job. The hook can affect only the Resource_List and project job attributes.

The input job attributes on which postqueuejob hooks operate are those that exist after the job is enqueued. For postqueuejob hooks, the input job attributes include:

- Server or queue resources_default or default_chunk
- Conversions from old syntax (-lnodes or -lncpus) to new select and place syntax

6.3.1.3.ii The postqueuejob Hook Interface

The event type for this event is pbs.POSTQUEUEJOB.

A postqueuejob hook runs after the job is queued, including when a job is peer queued to a server that has a postqueuejob hook. (See Figure 4-6.)

The hook is triggered by `qsub` or the `pbs_submit()` API call.

A postqueuejob hook is not triggered by requeueing a job (`qrerun`) or on node_fail_requeue, when a job is discarded by the MoM because the execution host went down.

A postqueuejob hook runs once per subjob.

A postqueuejob hook runs as *pbsadmin*.

A pbs.POSTQUEUEJOB event has the following member, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().job

A pbs.job object with the attributes and resources assigned after the job is queued. See section 6.6, "Job Objects", on page 132.

A pbs.POSTQUEUEJOB event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

A pbs.event().accept() terminates hook execution, and any changes to job attributes or resources take effect.

A pbs.event().reject() terminates hook execution, and no changes are made to the job.

6.3.1.4 movejob: Event when Job is Moved

6.3.1.4.i Modifying Job Move (`qmove`)

- When a job is moved via `qmove`, movejob hooks can modify the arguments passed to `qmove`
- When a movejob hook runs, it can change the job's destination queue to any queue on the default server

  A movejob hook can specify only local queues as the destination queue. Whether a job is submitted with a local queue or a remote queue as its destination, a movejob hook can change the destination to a local queue.

The only job attribute that a movejob event hook can set is the job's destination queue.

6.3.1.4.ii The movejob Hook Interface

The type for this event is pbs.HOOK_EVENT_MOVEJOB.

The server runs its movejob hooks when any of the following happens:

- This server is the furnishing server when peer scheduling a job
- A job is moved from this server to another server via the `qmove` command
- A job is moved between two queues on this server

A movejob hook is executed after `qmove` arguments are processed, but before a job is moved from one queue to another. This hook is triggered by `qmove` and the `pbs_movejob()` API call. movejob hooks are not triggered by `pbs_rsub -Wqmove=<job ID>`. A movejob hook runs once per job array.

A job object's attributes appear to a movejob hook as they would be after the event, not before it.

The hook shows the job's originating queue in the pbs.event().src_queue object member.

A pbs.HOOK_EVENT_MOVEJOB event has the following members, in addition to those listed insection 6.3.2, “Event Object Members”, on page 116:

pbs.event().job

A pbs.job object representing the job being moved. See section 6.6, “Job Objects”, on page 132.

Note that pbs.event().job.queue refers to the destination queue, not the current queue.

pbs.event().src_queue

The pbs.queue object representing the originating queue where pbs.event().job came from.

A pbs.event().accept() terminates hook execution and allows the job to be moved, and any changes to job attributes or resources take effect.

A pbs.event().reject() terminates hook execution and causes the job not to be moved.

6.3.1.5 modifyjob: Event when Job is Altered

6.3.1.5.i Modifying Job Change (`qalter`)

- When a job is changed via `qalter`, modifyjob hooks can modify the arguments passed to `qalter`
- When a modifyjob hook runs, it can change the attributes of the job that can be changed via `qalter`

Before the job runs, this hook can set any job attribute that can be changed via `qalter`, can set the job's comment, and can set any resource requested by the job.

While the job is running, the only job attributes and resources that the hook can set are those that can be changed via the `qalter` command: the job's cput and walltime. See section 5.2.4, “Using Attributes and Resources in Hooks”, on page 45, for a complete listing of attributes and resources that this hook can modify.

See “qalter” on page 130 of the PBS Professional Reference Guide and “Job Attributes” on page 327 of the PBS Professional Reference Guide.

6.3.1.5.ii The modifyjob Hook Interface

The type for this event is pbs.HOOK_EVENT_MODIFYJOB.

A modifyjob hook is executed after all processing of `qalter` input, and just before the job's attributes are modified. The hook is triggered by the following:

- A `qalter` command, except when the scheduler calls the command
- The `pbs_alterjob()` API call
- Calculating eligible time
- Setting the job's comment

A modifyjob hook runs once per job array.

In a modifyjob event hook, the pbs.event().job object's attributes appear to a modifyjob hook as they would be after the job is modified, not before.

A modifyjob event hook shows the original job with all its attributes in pbs.event().job_o.

A pbs.HOOK_EVENT_MODIFYJOB event has the following members, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().job

A pbs.job object representing the job changes being requested. See section 6.6, "Job Objects", on page 132. In this job object, only attributes and resources that are to be modified by the `qalter` command are populated, and they are populated with the new requested values. In this job object, attributes or resources that are not slated to be modified are not populated.

pbs.event().job_o

A read-only pbs.job object representing the original job, before the job was modified via `qalter`. All attributes and resources are populated. See section 6.3.2.12, "Original Job Event Member", on page 121.

A pbs.HOOK_EVENT_MODIFYJOB event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

A pbs.event().accept() terminates hook execution and allows the job to be altered, and any changes to job attributes or resources take effect.

A pbs.event().reject() terminates hook execution and causes the job not to be altered.

6.3.1.6 runjob: Event Before Job is Received by MoM

6.3.1.6.i Changes Before Job is Sent to MoM (`qrun`)

When the scheduler runs a job or the administrator runs a job using the `qrun` command, any runjob hooks are executed.

- On accepting a job, a runjob hook can modify the following:
  - The job's Error_Path attribute
  - The job's Output_Path attribute
  - All of the job's Variable_List attribute members
  - The following Resource_List attribute members:

    cput

    exec_vnode

    file

    max_walltime

    min_walltime

    nice

    pcput

    pmem

    pvmem

    site

    software

    start_time

    walltime
- When a runjob hook rejects a job, it can do the following:
  - Set the job's depend attribute
  - Set any members of the job's Variable_List attribute
  - Place a hold on the job
  - Release a hold on the job
  - Set the job's project attribute
  - Change the time the job is allowed to begin execution
  - Set any of the job's Resource_List attribute members except nodect
  - Change the state of a vnode where the job would have run

We list the job resources that can be read and set via a runjob event in Table 5-11, “Built-in Job Resources Readable & Settable by Hooks via Job Events,” on page 64 and Table 5-12, “Built-in Job Resources Readable & Settable by Hooks via Reservation & Other Non-job Events,” on page 65.

We list the vnode resources that can be read and set via a runjob event in Table 5-13, “Vnode Resources Readable & Settable by Hooks via Job Events,” on page 66 and Table 5-14, “Vnode Resources Readable & Settable by Hooks via Reservation & Other Non-job Events,” on page 67.

A runjob hook can modify a vnode only if the hook rejects the event, and the vnode is in the job's exec_vnode attribute. For a vnode, the hook can modify only the state attribute. The only pre-execution event hook that can change this attribute is a runjob hook.

6.3.1.6.ii The runjob Hook Interface

The event type is pbs.HOOK_EVENT_RUNJOB.

A runjob event occurs when one of the following happens:

- The administrator uses the `qrun` command
- The scheduler chooses to run a job and calls `pbs_runjob()`

A runjob hook is executed just before a job is sent to the execution host. It is triggered by `qrun` and the `pbs_runjob()` API call. A runjob hook runs once per subjob.

For a runjob hook only, job object attributes appear as they would be before the event takes place.

A pbs.HOOK_EVENT_RUNJOB event has the following member, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().job

A pbs.job object representing the job being run. See section 6.6, "Job Objects", on page 132.

A pbs.HOOK_EVENT_RUNJOB event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

A pbs.event().accept() terminates hook execution and allows the job to be sent to the execution host, and any changes to job attributes or resources take effect.

A pbs.event().reject() terminates hook execution and causes the job to be requeued instead of being sent to the execution host. When a job is requeued by this hook, the scheduler considers it for execution in the next scheduling cycle.

6.3.1.7 jobobit: Event when Server Receives Job or Subjob Obit

When the server receives a job or subjob obit, a jobobit hook has read-only access to the job or subjob.

6.3.1.7.i The jobobit Hook Interface

This event type is pbs.HOOK_EVENT_JOBOBIT.

The jobobit hook runs on the server host when:

- Job finishes execution
- Subjob finishes execution
- Job array parent job ends
- A job is requeued in order to rerun it
- A running job is deleted and the primary MoM cannot be reached
- A running job is deleted by force

The jobobit hook runs as *pbsadmin*.

A pbs.HOOK_EVENT_JOBOBIT event has the following member, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().job

A read-only pbs.job object representing the job or subjob leaving execution. See section 6.6, "Job Objects", on page 132.

If this job is in a reservation, the job object has a read-only reservation object as a member:

pbs.event().job.resv

A read-only pbs.resv object representing the reservation the job is in. See section 6.9, "Reservation Objects", on page 144.

A pbs.HOOK_EVENT_JOBOBIT event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

A call to pbs.event().accept() or to pbs.event().reject(<message>) terminates hook execution. Neither call has any effect on the job.

If the jobobit hook script encounters an unexpected error causing an unhandled exception, or if the script terminates due to a hook alarm, the error is logged in the server log.

6.3.1.8 resvsub: Event when Reservation is Created

6.3.1.8.i Modifying Reservation Creation (`pbs_rsub`)

- When an advance, standing, or job-specific reservation is created via `pbs_rsub`, resvsub hooks can modify the reservation's attributes that can be set via `pbs_rsub`
- When an advance, standing, or job-specific reservation is created, resvsub hooks can specify additional attributes that can be specified via `pbs_rsub`
- The input reservation attributes on which resvsub hooks operate are those that exist after all `pbs_rsub` processing of command line arguments is completed
- For resvsub hooks, the input reservation attributes do not include:
  - Server or queue resources_default or default_chunk.
  - Conversions from old syntax (-lnodes & -lncpus) to new select and place syntax

The only time that a reservation can be modified is during its creation. A resvsub event hook can set any settable reservation attribute and any resource that can be specified via `pbs_rsub`. See Table 5-10, "Reservation Attributes Readable & Settable in Reservation Hooks," on page 63 for a complete list of the reservation attributes that this hook can read and set.

6.3.1.8.ii The resvsub Hook Interface

The type for this event is pbs.HOOK_EVENT_RESVSUB.

A resvsub hook is executed after all processing of `pbs_rsub` input, and just before a reservation is created. The hook is triggered by `pbs_rsub` and the `pbs_submitresv()` API call.

A reservation object's attributes appear to a resvsub hook as they would be after the event, not before it.

A pbs.HOOK_EVENT_RESVSUB event has the following member, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().resv

A pbs.resv object containing the attributes and resources specified for the reservation being requested. See section 6.9, "Reservation Objects", on page 144.

A pbs.HOOK_EVENT_RESVSUB event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

A pbs.event().accept() terminates hook execution and allows creation of the reservation, and any changes to reservation resources take effect.

A pbs.event().reject() terminates hook execution and causes the reservation not to be created.

6.3.1.9 resv_confirm: Event when Reservation is Confirmed

6.3.1.9.i Reservation Confirmation

- When an advance, standing, or job-specific reservation is created via `pbs_rsub`, resv_confirm hooks has read-only access to the reservation object
- The input reservation attributes on which resv_confirm hooks operate are those that exist after the reservation is confirmed

See Table 5-10, "Reservation Attributes Readable & Settable in Reservation Hooks," on page 63 for a complete list of the reservation attributes that this hook can read.

6.3.1.9.ii The resv_confirm Hook Interface

The type for this event is pbs.HOOK_EVENT_RESV_CONFIRM

The hook is triggered by `pbs_rsub` and the `pbs_submitresv()` API call.

A resvconfirm hook runs as *pbsadmin*.

A pbs.HOOK_EVENT_RESV_CONFIRM event has the following member, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().resv

A pbs.resv object containing the attributes and resources specified for the reservation being requested. See section 6.9, "Reservation Objects", on page 144.

A pbs.HOOK_EVENT_RESV_CONFIRM event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

A pbs.event().accept() terminates hook execution.

A pbs.event().reject() terminates hook execution and stops any other pbs.HOOK_EVENT_RESV_CONFIRM hooks from being triggered.

6.3.1.10 modifyresv: Event when Reservation is Altered

6.3.1.10.i Modifying Reservation Changes (`pbs_ralter`)

A modifyresv event hook can set any settable reservation attribute and any resource that can be specified via `pbs_ralter`. See Table 5-10, "Reservation Attributes Readable & Settable in Reservation Hooks," on page 63 for a complete list of the reservation attributes that this hook can read and set.

6.3.1.10.ii The modifyresv Hook Interface

The type for this event is pbs.HOOK_EVENT_MODIFYRESV.

A modifyresv hook is executed before processing of `pbs_ralter` input, just before the reservation is changed.

The hook is triggered by `pbs_ralter` and the `pbs_modify_resv()` API call.

A modifyresv hook runs as *pbsadmin*.

A pbs.HOOK_EVENT_MODIFYRESV event has the following members, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().resv

A pbs.resv object containing the list of requested changes. See section 6.9, "Reservation Objects", on page 144.

pbs.event().resv_o

A read-only pbs.resv object containing the attributes and resources of the reservation before the changes are made. See section 6.9, "Reservation Objects", on page 144.

A pbs.HOOK_EVENT_MODIFYRESV event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

A pbs.event().accept() terminates hook execution and allows changing and reconfirming the reservation.

A pbs.event().reject() terminates hook execution; there is no change to the reservation and the reservation is not reconfirmed.

6.3.1.11 resv_begin: Event when Reservation Starts

6.3.1.11.i Reservation Start

- When an advance, standing, or job-specific reservation starts, resv_begin hooks have read-only access to the reservation object

See Table 5-10, "Reservation Attributes Readable & Settable in Reservation Hooks," on page 63 for a complete list of the reservation attributes that this hook can read.

6.3.1.11.ii The resv_begin Hook Interface

The type for this event is pbs.HOOK_EVENT_RESV_BEGIN.

A resv_begin hook is executed when a reservation or an instance of a standing reservation begins.

A resv_begin hook runs as *pbsadmin*.

A pbs.HOOK_EVENT_RESV_BEGIN event has the following member, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().resv

A read-only pbs.resv object containing the attributes and resources specified for the reservation. See section 6.9, "Reservation Objects", on page 144.

A pbs.HOOK_EVENT_RESV_BEGIN event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

A pbs.event().accept() terminates hook execution.

A pbs.event().reject() terminates hook execution.

6.3.1.12 resv_end: Event when Reservation Ends

A resv_end event hook can read server and reservation attributes. See Table 5-10, "Reservation Attributes Readable & Settable in Reservation Hooks," on page 63 for a complete list of the reservation attributes that this hook can read.

6.3.1.12.i The resv_end Hook Interface

The type for this event is pbs.HOOK_EVENT_RESV_END.

A resv_end hook runs as *pbsadmin*.

Triggered by `pbs_rdel` or the `pbs_delresv` API call, for an advance reservation or an instance of a standing reservation.

A resv_end hook is executed when a confirmed reservation ends or is deleted.

Runs just before jobs are deleted from the reservation queue.

A pbs.HOOK_EVENT_RESV_END event has the following member, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().resv

A pbs.resv object containing the attributes and resources specified for the reservation being requested. See section 6.9, "Reservation Objects", on page 144.

A pbs.HOOK_EVENT_RESV_END event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

A pbs.event().reject() does not interrupt the execution of the process invoking it.

6.3.1.13 management: qmgr Operation Event at Server Host

6.3.1.13.i qmgr Operation Events at Server Host

After `qmgr` is used to operate on an object, a management hook can report on the operation. The hook has read-only access to the changes made using `qmgr`. The hook can report information about the requested operation, any associated attributes, and the status of the completed operation.

This hook is useful for logging changes made by administrators and for figuring out why the behavior of PBS has changed. You can use it to track server management operations, such as adding a new node, importing a hook script, etc.

This hook is triggered by operations that use `qmgr` directives such as `create`, `set`, or `import`, to operate on PBS objects such as vnodes, attributes, or hooks. This hook is not triggered by qmgr directives that do not act on objects, such as `print`, `exit`, or `help`. For a list of hook triggers and objects see section 6.11, "Management Objects", on page 150.

This event contains information about whether the server management operation succeeded or failed.

6.3.1.13.ii The management Hook Interface

This event type is pbs.HOOK_EVENT_MANAGEMENT.

A management hook script is executed by the server after a server management operation is completed.

The management hook runs as *pbsadmin*.

A pbs.HOOK_EVENT_MANAGEMENT event has the following member, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().management

A pbs.management object representing the PBS server management operation that was executed. The management object and the operation cannot be modified with this hook event. See section 6.11, "Management Objects", on page 150.

A pbs.HOOK_EVENT_MANAGEMENT event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

A call to pbs.event().accept() terminates hook execution. No change is made to the operation.

A call to pbs.event().reject(<message>) prevents any management hooks with higher order from being triggered. No change is made to the operation.

If the management hook script encounters an unexpected error causing an unhandled exception, or times out due to the hook's alarm setting, the hook will behave as it does on a pbs.event().reject().

6.3.1.14 periodic: Periodic Event at Server Host

6.3.1.14.i Periodic Events at Server Host

Periodically, at the server host, a periodic hook can:

- Run `qstat`, job start time estimator named `pbs_est`, etc.

6.3.1.14.ii The periodic Hook Interface

This event type is pbs.HOOK_EVENT_PERIODIC.

The periodic hook runs periodically on the server host, in the background. The hook begins periodic execution, and the interval timer is restarted, when any of the following happens:

- The hook is enabled
- The hook is imported
- The server starts

The periodic hook runs as *pbsadmin*.

The interval between calls to periodic hooks is specified in the freq hook attribute. See section 5.1.13, "Setting Hook Interval (Frequency)", on page 40.

A pbs.HOOK_EVENT_PERIODIC event has the following member, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().vnode_list[]

This is a dictionary of pbs.vnode objects, keyed by vnode name. See section 6.3.2.24, "The Vnode List Event Member", on page 123 for information about using pbs.event().vnode_list[].

A pbs.HOOK_EVENT_PERIODIC event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

A call to pbs.event().accept() causes any changes made to objects exposed in the hook to take effect.

A call to pbs.event().reject(<message>) prevents any changes from taking effect.

A call to pbs.event().reject(<message>) causes the following messages to appear in the server log:

```
"run_periodic_hook; request rejected by <hook_name>"
<message>
```

The periodic hook continues to be periodically called whether or not there are errors in hook script execution or a call to the pbs.event().reject() action. To stop the hook from being called, either disable it or delete it:

```
#qmgr -c "s h <periodic hook> enabled=f"
#qmgr -c "d h <periodic hook>"
```

If the periodic hook script encounters an unexpected error causing an unhandled exception, or if the script terminates due to a hook alarm, all changes do **not** take effect. In addition, one of the following messages appears in the MoM log at event class PBSEVENT_DEBUG2:

```
"periodic hook <hook_name> encountered an exception, request rejected"
"alarm call while running periodic hook '<hook_name>', request rejected"
```

6.3.1.14.iii Caveats for periodic Event Hooks

The order attribute is ignored for periodic hooks. It does **not** guarantee the execution order of a list of periodic hooks.

6.3.1.15 modifyvnode: Event after Vnode Changes State

6.3.1.15.i Vnode State Change

After a vnode changes state, a modifyvnode hook has read-only access to two vnode objects, one of which represents the current (modified) state, and one of which represents the previous (unmodified) state. For each, the hook can read, but not set, vnode attributes and resources.

6.3.1.15.ii The modifyvnode Hook Interface

The type for this event is pbs.HOOK_EVENT_MODIFYVNODE.

A modifyvnode hook is executed after a vnode changes state. The hook is triggered by a vnode state change.

A modifyvnode hook runs as *pbsadmin*.

A pbs.HOOK_EVENT_MODIFYVNODE event has the following members, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().vnode

A read-only pbs.vnode object representing the vnode after the state change.

pbs.event().vnode_o

A read-only pbs.vnode object representing the the original vnode with all its attributes before the state change.

A pbs.HOOK_EVENT_MODIFYVNODE event has the following methods, in addition to those listed in section 6.15.2, "Methods Available in Events", on page 165:

pbs.event().vnode.extract_state_ints()

Returns a list of the string values currently set in the vnode's state bits

pbs.event().vnode.extract_state_strs()

Returns a list of the integer values currently set in the vnode's state bits

See section 6.10, "Vnode Objects", on page 146.

A pbs.event().accept() or pbs.event().reject() terminates hook execution. The vnode and vnode_o objects are unaffected by either call.

For an example of a modifyvnode hook, see section 9.10, "modifyvnode Hook Example", on page 313.

6.3.1.15.iii Caveats for modifyvnode Hooks

Vnodes often undergo many state changes per administrative command. We recommend running a modifyvnode hook only when necessary, and making your modifyvnode hooks as efficient and fast as possible. See section 5.3.6, "Use Fast Operations", on page 75.

6.3.1.16 execjob_begin: Event when Execution Host Receives Job

6.3.1.16.i Changes When Job is Received by MoM

When MoM receives a job, an execjob_begin hook can:

- Modify the job's Execution_Time, Hold_Types, Variable_List, and resources_used attributes
- Flag the job to be rerun
- Kill the job
- Set attributes and resources on the vnode(s) managed by the MoM where this job executes

6.3.1.16.ii The execjob_begin Hook Interface

This event type is pbs.HOOK_EVENT_EXECJOB_BEGIN.

An execjob_begin hook executes on the primary MoM host and then, if successful, executes on all the sister MoM hosts allocated to the job. The hook executes when the host first receives the job, after any files or directories are staged in.

A pbs.HOOK_EVENT_EXECJOB_BEGIN event has the following members and methods, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().job

This is a pbs.job object representing the job that is about to run. See section 6.6, "Job Objects", on page 132.

pbs.event().vnode_list[]

This is a dictionary of pbs.vnode objects, keyed by vnode name, listing the vnodes that are assigned to this job. See section 6.3.2.24, "The Vnode List Event Member", on page 123 for information about using pbs.event().vnode_list[].

A pbs.HOOK_EVENT_EXECJOB_BEGIN event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

A call to pbs.event().accept() means the job can proceed with execution, and any changes to job attributes, resources, or the vnode list take effect.

A call to pbs.event().reject(<message>) automatically causes the job to be killed and tells the server to requeue the job. In addition, any changes to job attributes, resources, or vnode list take effect. When a job is requeued by this hook, the scheduler considers it for execution in the next scheduling cycle.

- If the pbs.event().reject(<message>) call is made on a primary execution host, the following message appears in the MoM log at log event class PBSEVENT_DEBUG2:

  "execjob_begin request rejected by <hook_name>"

  <message>

  The rejection message <message> also appears in the STDERR of the program such as qrun invoking pbs_runjob() API:
- If the pbs.event().reject(<message>) call is made on a sister host, the following message appears in the MoM log at log event class PBSEVENT_DEBUG2:

  "execjob_begin request rejected by <hook_name>"

  <message>

  In addition, this message appears in mom_logs on the primary execution host:

  "job_start_error: <hook errno> from node <hostname> could not JOIN_JOB successfully.
- If pbs_runjob() was invoked by the scheduler, the following job comment appears:

  "Not running: PBS Error: <message>"

If the execjob_begin hook script encounters an unexpected error causing an unhandled exception, or if the script terminates due to a hook alarm, the job is automatically killed and the server requeues the job. All job changes, vnode changes, or requests for host reboot or scheduler cycle restarts do **not** take effect. In this case, one of the the following messages appears in the MoM log at event class PBSEVENT_DEBUG2:

"execjob_begin hook <hook_name> encountered an exception, request rejected"

"alarm call while running execjob_begin hook '<hook_name>', request rejected"

6.3.1.17 execjob_prologue: Event Just Before Execution of Top-level Job Process

6.3.1.17.i Changes Before Job Shell is Executed

Just before a job's top shell is executed, an execjob_prologue hook can:

- Modify the job's Execution_Time, Hold_Types, and resources_used attributes
- Flag the job to be rerun
- Kill the job
- Set attributes and resources on the vnode(s) managed by the MoM where this job executes
- Modify a job's vnode request
- Put a bad vnode in the pbs.event().vnode_list_fail[] list

6.3.1.17.ii The execjob_prologue Hook Interface

This event type is pbs.HOOK_EVENT_EXECJOB_PROLOGUE.

An execjob_prologue hook runs on the primary MoM host. If the hook runs successfully on the primary MoM host, an execjob_prologue hook runs on each of the sister MoM hosts allocated to the job. On the primary MoM host, an execjob_prologue hook executes just prior to executing the top-level shell or cmd process of the job. This is where the prologue executes. On a sister MoM host, the hook executes just before the first task of the job on this host is spawned, and before any execjob_launch or execjob_attach hooks. See Table 4-1, "Execution Event Hook Timing," on page 20.

An execjob_prologue hook overrides a prologue. If an execjob_prologue hook exists and is enabled, MoM executes the hook. Otherwise, she executes the prologue.

A pbs.HOOK_EVENT_EXECJOB_PROLOGUE event has the following members, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().job

This is a pbs.job object representing the job that is about to run. See section 6.6, "Job Objects", on page 132.

pbs.event().vnode_list[]

This is a dictionary of pbs.vnode objects, keyed by vnode name, listing the vnodes that are assigned to this job. See section 6.3.2.24, "The Vnode List Event Member", on page 123 for information about using pbs.event().vnode_list[].

This is a pbs.job object representing the job that is about to run. See section 6.6, "Job Objects", on page 132.

pbs.event().vnode_list_fail[]

This is a dictionary of pbs.vnode objects, keyed by vnode name, listing the vnodes that are assigned to this job but are marked as unhealthy. See section 6.3.2.25, "The Failed Vnode List Event Member", on page 125 for information about pbs.event().vnode_list_fail[].

A pbs.HOOK_EVENT_EXECJOB_PROLOGUE event has the following methods, in addition to those listed in section 6.15.2, "Methods Available in Events", on page 165:

pbs.event().job.release_nodes()

This method releases unneeded vnodes from a job's vnode request. See section 6.6.2.4, "Job Object Method to Release Vnodes", on page 141.

A pbs.event().accept() allows the job to continue its normal execution, and any changes to job attributes, resources, or vnode list take effect.

A pbs.event().reject(<message>) causes the job to be killed, and the owning server to requeue the job. Any changes to job attributes, resources, or vnode list take effect. When a job is requeued by this hook, the scheduler considers it for execution in the next scheduling cycle.

- On the primary execution host, the following job-level mom_logs entries appear:

  "execjob_prologue request rejected by <hook_name>"

  <message>
- On a sister vnode, the following job-level mom_logs entries appear:

  "execjob_prologue request rejected by <hook_name>"

  <message>
- In addition, the following message appears in the STDERR of the program invoking the tm_attach() API, such as the pbs_attach() command:

  "a hook has rejected the task manager request"

If the following setting is specified in the hook script, just before issuing a pbs.event().reject(), the job is deleted instead of being requeued:

```
pbs.event().job.delete()
```

If the user attribute of the execjob_prologue hook is set to *pbsuser*, the hook script executes under the context of the job owner (the value of the euser job attribute).

If the execjob_prologue hook script encounters an unexpected error causing an unhandled exception, or if the script terminates due to a hook alarm, the job is killed and the server requeues the job. All job changes, vnode changes, or requests for host reboot or scheduler cycle restarts, do **not** take effect. In addition, one of the following messages appears in the MoM log at event class PBSEVENT_DEBUG2:

```
"execjob_prologue hook <hook_name> encountered an exception, request rejected"
"alarm call while running execjob_prologue hook '<hook_name>', request rejected"
```

The standard output and standard error of an execjob_prologue hook script are not connected to the standard output and standard error of the job.

6.3.1.18 execjob_launch: Event when Execution Host Receives Job

6.3.1.18.i Changes Before User Program is Executed

Just before the user's program is executed, an execjob_launch hook can:

- Change the job's top shell or executable
- Change the arguments to the shell or executable
- Change the job's environment variables
- Modify job and vnode attributes
- Modify a job's vnode request and list
- Put a bad vnode in the pbs.event().vnode_list_fail[] list

An execjob_launch hook cannot modify anything else.

6.3.1.18.ii The execjob_launch Hook Interface

This event type is pbs.HOOK_EVENT_EXECJOB_LAUNCH.

An execjob_launch hook runs on the primary MoM host just before executing the user's program. The hook runs on the sister MoM hosts allocated to the job, just before executing the user's program as specified in a `tm_spawn()` API call, which is called from `pbsdsh` and `pbs_tmrsh`.

Any execjob_launch hooks runs after execjob_prologue hooks.

This hook cannot use any of the job's methods.

A pbs.HOOK_EVENT_EXECJOB_LAUNCH event hook has access to the following members, in addition to those listed in section 6.3.2, “Event Object Members”, on page 116:

pbs.event().argv[]
: This is a pbs.argv[] object representing the arguments to the shell or executable. See section 6.3.2.2, “Job Program Arguments Event Member”, on page 118.

pbs.event().env
: This is a pbs.env[] object representing the job's environment variables. See section 6.3.2.5, “Job Environment Event Member”, on page 119.

pbs.event().job
: This is a pbs.job object representing the job that is about to run. See section 6.6, “Job Objects”, on page 132.

pbs.event().progname
: This is a pbs.progname object representing the job shell or executable. See section 6.3.2.15, “Job Executable Event Member”, on page 121.

pbs.event().vnode_list[]
: This is a dictionary of pbs.vnode objects, keyed by vnode name, listing the vnodes that are assigned to the job that caused the execjob_launch hook to execute. See section 6.3.2.24, “The Vnode List Event Member”, on page 123 for information about pbs.event().vnode_list[].

pbs.event().vnode_list_fail[]

This is a dictionary of pbs.vnode objects, keyed by vnode name, listing the vnodes that are assigned to this job but are marked as unhealthy. Seesection 6.3.2.25, “The Failed Vnode List Event Member”, on page 125 for information about pbs.event().vnode_list_fail[].

A pbs.HOOK_EVENT_EXECJOB_LAUNCH event has the following methods, in addition to those listed in section 6.15.2, “Methods Available in Events”, on page 165:

pbs.event().job.release_nodes()

This method releases unneeded vnodes from a job's vnode request. See section 6.6.2.4, “Job Object Method to Release Vnodes”, on page 141.

A call to pbs.event().accept() means the job can proceed with execution, and any changes to progname, argv[], and env[] take effect. If the hook makes changes to the job's progname, argv[], or env[] parameters, the appropriate PBSEVENT_DEBUG2 message(s) appear in mom_logs for each change in a value:

```
"progname orig: <original_progname>"
"progname new: <updated_progname>"
"argv orig: <original_argv>"
"argv new: <updated_argv>"
"env orig: <original_env>"
"env new: <updated_env>"
```

A call to pbs.event().reject(<message>) causes the job to be terminated with a non-zero Exit_Status value, and the following PBSEVENT_DEBUG2 messages to appear in mom_logs:

```
"execjob_launch" request rejected by '<hook_name>'"
<message>
```

If the execjob_launch hook script encounters an unexpected error causing an unhandled exception, the job is terminated with a non-zero Exit_Status value, and the following PBSEVENT_DEBUG2 messages appear in mom_logs:

```
"execjob_launch hook <hook_name> encountered an exception, request rejected"
```

If the execjob_launch hook script terminates due to a hook alarm, the job is terminated with a non-zero Exit_Status value, and the following PBSEVENT_DEBUG2 messages appear in mom_logs:

```
"alarm call while running execjob_launch hook '<hook_name>', request rejected"
```

6.3.1.19 execjob_attach: Event when pbs_attach() runs

6.3.1.19.i Event when pbs_attach() Runs

When pbs_attach() is called, an execjob_attach hook can accept or reject the procedure where the process ID is attached to the job.

6.3.1.19.ii The execjob_attach Hook Interface

An execjob_attach hook runs on any MoM host where an MPI process is spawned using pbs_attach(). The execjob_attach hook runs for each process ID.

The execjob_attach hook runs before any execjob_prologue hooks run on behalf of the first task. See Table 4-1, “Execution Event Hook Timing,” on page 20.

An execjob_attach hook cannot modify any PBS objects.

A pbs.HOOK_EVENT_EXECJOB_ATTACH event has the following members, in addition to those listed in section 6.3.2, “Event Object Members”, on page 116:

pbs.event().job

This is a pbs.job object representing the job that is about to run. See section 6.6, "Job Objects", on page 132. For this hook, this job object is read-only.

pbs.event().pid

This is a Python int representing the process ID whose session ID is being added to the job tasks list. This hook cannot modify the value of the process ID.

pbs.event().vnode_list[]

This is a dictionary of pbs.vnode objects, keyed by vnode name, listing the vnodes that are assigned to this job. The list of vnodes is read-only for this event. See section 6.3.2.24, "The Vnode List Event Member", on page 123 for information about using pbs.event().vnode_list[].

A pbs.HOOK_EVENT_EXECJOB_BEGIN event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

On a call to pbs.event().accept(), MoM proceeds as usual to add the session ID of the process ID to the job's task list.

On a call to pbs.event().reject(<message>), the following happens:

- Hook execution terminates
- MoM does not get the session ID
- PBS prints the following message in mom_logs at log level PBSEVENT_DEBUG2:

  "execjob_attach" request rejected by '<hook_name>'"

  <message>

If the execjob_attach hook script encounters an unhandled exception:

- Hook execution terminates
- MoM does not get the session ID of the process ID
- The following message appears in mom_logs at PBSEVENT_DEBUG2:

  "execjob_attach hook <hook_name> encountered an exception, request rejected"

If the execjob_attach hook script terminates due to a hook alarm, MoM does not get the session ID of the process ID, and the following message appears in mom_logs at PBSEVENT_DEBUG2:

"alarm call while running execjob_attach hook '<hook_name>', request rejected"

6.3.1.19.iii Caveats for execjob_attach Hooks

- Do not attempt to modify pbs.event().pid. If you do:
  - Hook execution is terminated
  - MoM does not get the session ID of the process ID
  - The following messages appear in mom_logs at PBSEVENT_DEBUG2:

    "execjob_attach hook <hook_name> encountered an exception, request rejected"

    "event attribute 'pid' is read-only"
- Do not attempt to modify pbs.event().job or the objects in pbs.event().vnode_list[]. If you do:
  - Hook execution is terminated
  - MoM does not get the session ID of the process ID
  - The following messages appear in mom_logs at PBSEVENT_DEBUG2:

    "execjob_attach hook <hook_name> encountered an exception, request rejected"

    "nothing is settable inside an execjob_attach hook!"

6.3.1.20 execjob_postsuspend: Event Just After Suspending Job

6.3.1.20.i The execjob_postsuspend Hook Interface

This event type is pbs.HOOK_EVENT_EXECJOB_POSTSUSPEND.

This hook runs on all of the MoM hosts assigned to a job, after the job has been successfully suspended.

An execjob_postsuspend hook:

- Cannot modify any PBS objects
- Cannot be used to set a fail action
- Must run as *pbsadmin*
- Does not interrupt the flow of suspend/resume

A pbs.HOOK_EVENT_EXECJOB_POSTSUSPEND event has the following members, in addition to those listed in section 6.3.2, “Event Object Members”, on page 116:

pbs.event().job

This is a pbs.job object representing the job that has just been suspended. See section 6.6, “Job Objects”, on page 132. For this hook, this job object is read-only.

pbs.event().vnode_list[]

This is a dictionary of pbs.vnode objects, keyed by vnode name, listing the vnodes that are assigned to this job. The list of vnodes is read-only for this event. See section 6.3.2.24, “The Vnode List Event Member”, on page 123 for information about using pbs.event().vnode_list[].

A pbs.HOOK_EVENT_EXECJOB_POSTSUSPEND event has the methods listed in section 6.15.2, “Methods Available in Events”, on page 165.

On a call to pbs.event().accept(), nothing happens.

On a call to pbs.event().reject(<message>), the following happens:

- Hook execution terminates
- PBS prints the following message in mom_logs at log level PBSEVENT_DEBUG2:

  "execjob_postsuspend" request rejected by '<hook_name>'"

  <message>

6.3.1.21 execjob_preresume: Event Just Before Resuming Job

6.3.1.21.i The execjob_preresume Hook Interface

This event type is pbs.HOOK_EVENT_EXECJOB_PRERESUME.

This hook runs on the primary MoM host when this MoM receives a request to resume a job, and then if this is successful, the primary MoM sends a request to the sisters to resume the job, at which point this hook runs on the sister MoM hosts. All of the execjob_preresume hooks for a job must succeed in order for the job to resume.

An execjob_preresume hook:

- Cannot modify any PBS objects
- Cannot be used to set a fail action
- Must run as *pbsadmin*

A pbs.HOOK_EVENT_EXECJOB_PRERESUME event has the following members, in addition to those listed in section 6.3.2, “Event Object Members”, on page 116:

pbs.event().job

This is a pbs.job object representing the job that has just been suspended. See section 6.6, "Job Objects", on page 132. For this hook, this job object is read-only.

pbs.event().vnode_list[]

This is a dictionary of pbs.vnode objects, keyed by vnode name, listing the vnodes that are assigned to this job. The list of vnodes is read-only for this event. See section 6.3.2.24, "The Vnode List Event Member", on page 123 for information about using pbs.event().vnode_list[].

A pbs.HOOK_EVENT_EXECJOB_PRERESUME event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

On a call to pbs.event().accept(), nothing happens

On a call to pbs.event().reject(<message>), the following happens:

- Hook execution terminates
- All MoMs where job processes were running are prevented from resuming the job
- PBS prints the following message in mom_logs at log level PBSEVENT_DEBUG2:

  "execjob_preresume" request rejected by '<hook_name>'"

  <message>

6.3.1.22 execjob_preterm: Event Just Before Killing Job Tasks

6.3.1.22.i Changes Before Job is Killed

Just before a job is killed, an execjob_preterm hook can:

- Modify the job's Execution_Time, Hold_Types, and resources_used attributes
- Flag the job to be rerun
- Kill the job
- Set attributes and resources on the vnode(s) managed by the MoM where this job executes
- Cause the job to keep running

6.3.1.22.ii The execjob_preterm Hook Interface

This event type is pbs.HOOK_EVENT_EXECJOB_PRETERM.

An execjob_preterm hook executes on all the MoM hosts allocated to a job. This hook runs only when a qdel has been issued. It does not run for any other job termination. For example, it does not run on a qrerun or when a job goes over its limit. On the primary MoM host, the hook executes when the job receives a signal from the server for the job to terminate. On a sister MoM host, this hook executes when the sister receives a request from the primary MoM host to terminate the job, just before the sister signals the task on this host to terminate.

A pbs.HOOK_EVENT_EXECJOB_PRETERM event has the following members, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().job

This is a pbs.job object representing the job that is about to run (or be killed). See section 6.6, "Job Objects", on page 132.

pbs.event().vnode_list[]

This is a dictionary of pbs.vnode objects, keyed by vnode name, listing the vnodes that are assigned to this job. See section 6.3.2.24, "The Vnode List Event Member", on page 123 for information about using pbs.event().vnode_list[].

A pbs.HOOK_EVENT_EXECJOB_PRETERM event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

A pbs.event().accept() call allows job cancellation or deletion to happen, and any changes to job attributes, resources, or vnode list take effect.

A pbs.event().reject() call causes the job instance on a vnode to continue running, because the terminate signal is not delivered to the job. Any changes to job attributes, resources, or vnode list take effect.

- On the primary execution host, a pbs.event().reject(<message>) causes the following to appear in the STDERR of the program (qdel) invoking the pbs_deljob() API:
  "hook rejected request"
- The following message appears in the MoM log at log event class PBSEVENT_DEBUG2:
  "execjob_preterm request rejected by <hook_name>"
  <message>
- On a sister host, a pbs.event().reject(<message>) causes the following message to appear in the MoM log at log event class PBSEVENT_DEBUG2:
  "execjob_preterm request rejected by <hook_name>"
  <message>

If the user attribute of the execjob_preterm hook is set to *pbsuser*, the hook script executes under the context of the job owner (the value of the euser job attribute).

If the execjob_preterm hook script encounters an unexpected error causing an unhandled exception, or if the script terminates due to a hook alarm, the job continues to run, and all job changes, vnode changes, requests for host reboot or scheduler cycle restarts, do **not** take effect. In addition, one of the the following messages appears in the MoM log at event class PBSEVENT_DEBUG2:

"execjob_preterm hook <hook_name> encountered an exception, request rejected"
"alarm call while running execjob_preterm hook '<hook_name>', request rejected"

6.3.1.23 execjob_epilogue: Event Just After Killing Job Tasks

6.3.1.23.i Changes After Job is Executed

Just after a job is executed, an execjob_epilogue hook can:

- Modify the job's Execution_Time, Hold_Types, and resources_used attributes
- Flag the job to be rerun
- Kill the job
- Set attributes and resources on the vnode(s) managed by the MoM where this job executes
- Use the job's exit status

6.3.1.23.ii The execjob_epilogue Hook Interface

This event type is pbs.HOOK_EVENT_EXECJOB_EPILOGUE.

An execjob_epilogue hook executes on all the MoM hosts allocated to the job. On a primary MoM host, the hook executes after all the job tasks/processes on the host have been killed, and basic CPU and memory resource usage information have been logged, but before job processes are cleaned up. This is where the epilogue executes. On a sister MoM host, the hook executes after the sister MoM receives a request to kill the job and has signaled the job tasks to terminate.

When an execjob_epilogue hook modifies the resources_used job attribute, it is modifying only the value counted at the local host. For example, if a job runs on two hosts, using four minutes of CPU time on each host, and the hook changes that to three minutes (and this hook runs at both hosts), the job's final CPU time total is six minutes instead of eight.

An execjob_epilogue hook overrides an epilogue. If an execjob_epilogue hook exists and is enabled, MoM executes the hook. Otherwise, she executes the epilogue.

A pbs.HOOK_EVENT_EXECJOB_EPILOGUE event has the following members, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().job

This is a pbs.job object representing the job that just finished. See section 6.6, "Job Objects", on page 132.

pbs.event().vnode_list[]

This is a dictionary of pbs.vnode objects, keyed by vnode name, listing the vnodes that are assigned to this job. See section 6.3.2.24, "The Vnode List Event Member", on page 123 for information about using pbs.event().vnode_list[].

A pbs.HOOK_EVENT_EXECJOB_EPILOGUE event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

The execjob_epilogue hook has access to the job's exit status because it is available at this point. The exit status looks like this:

pbs.event().job.Exit_status

A Python int that holds the exit value of the top level shell of the job script. This value is valid only if the hook is executing on a primary execution host.

A call to pbs.event().accept() continues the normal end-of-job processing, and any changes to job attributes, resources, or vnode list take effect.

A call to pbs.event().reject() causes the job on the current vnode to exit, and the owning server to completely delete the job. Any changes to job attributes, resources, or vnode list take effect.

- On a primary execution host, a pbs.event().reject(<message>) causes the following message to appear in the MoM log at log event class PBSEVENT_DEBUG2:

  "execjob_epilogue request rejected by <hook_name>"

  <message>

- On a sister host, a pbs.event().reject(<message>) causes the following message to appear in the MoM log at log event class PBSEVENT_DEBUG2:

  "execjob_epilogue request rejected by <hook_name>"

  <message>

- If the following call has been made prior to calling pbs.event().reject(), the owning server requeues the job:

  pbs.event().job.rerun()

If the user attribute of the execjob_epilogue hook is set to *pbsuser*, the hook script executes under the context of the job owner (the value of the euser job attribute).

If the execjob_epilogue hook script encounters an unexpected error causing an unhandled exception, or if the script terminates due to a hook alarm, this causes the job on the current vnode to exit, and the owning server to completely delete the job. All job changes, vnode changes, requests for host reboot or scheduler cycle restarts, do **not** take effect. In addition, one of the following messages appears in the MoM log at event class PBSEVENT_DEBUG2:

"execjob_epilogue hook <hook_name> encountered an exception, request rejected"

"alarm call while running execjob_epilogue hook '<hook_name>', request rejected"

The standard output and standard error of an execjob_epilogue hook script are not connected to the standard output and standard error of the job.

6.3.1.24 execjob_end: Event After Job Cleanup

6.3.1.24.i Changes After Job Finishes or is Killed

Just after a job is cleaned up after it finishes execution or is killed, an execjob_end hook can:

- Set attributes and resources on the vnode(s) managed by the MoM where this job executes
- Use the job's exit status

An execjob_end hook cannot effectively modify the job's Execution_Time and Hold_Types attributes. These changes will not be visible to the server, because the job is already cleaned up and reported.

6.3.1.24.ii The execjob_end Hook Interface

This event type is pbs.HOOK_EVENT_EXECJOB_END.

An execjob_end hook executes on all the MoM hosts allocated to a job. The hook is executed after a job is cleaned up.

A pbs.HOOK_EVENT_EXECJOB_END event has the following members, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().job

This is a pbs.job object representing the job that just ran. See section 6.6, "Job Objects", on page 132.

pbs.event().vnode_list[]

This is a dictionary of pbs.vnode objects, keyed by vnode name, listing the vnodes that are assigned to this job. See section 6.3.2.24, "The Vnode List Event Member", on page 123 for information about using pbs.event().vnode_list[].

A pbs.HOOK_EVENT_EXECJOB_END event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

The execjob_end hook has access to the job's exit status because it is available at this point. The exit status looks like this:

pbs.event().job.Exit_status

A Python int that holds the exit value of the top level shell of the job script. This value is valid only if the hook is executing on a primary execution host.

A call to pbs.event().accept() ends the job, and any changes to job attributes, resources, or vnode list take effect.

A call to pbs.event().reject(<message>) also ends the job, and any changes to job attributes, resources, or vnode list also take effect.

A call to pbs.event().reject(<message>) on a primary execution host causes the following message to appear in the MoM log at log event class PBSEVENT_DEBUG2:

```
"execjob_end request rejected by <hook_name>"
<message>
```

A call to pbs.event().reject(<message>) on a sister host causes the following message to appear in the MoM log at log event class PBSEVENT_DEBUG2:

```
"execjob_end request rejected by <hook_name>"
<message>
```

If the execjob_end hook script encounters an unexpected error causing an unhandled exception, or if the script terminates due to a hook alarm, the job terminates, and all job changes, vnode changes, requests for host reboot or scheduler cycle restarts, do **not** take effect. In addition, one of the following messages appear in the MoM logs at event class PBSEVENT_DEBUG2:

```
"execjob_end hook <hook_name> encountered an exception, request rejected"
"alarm call while running execjob_end hook '<hook_name>', request rejected"
```

6.3.1.25 exechost_startup: Event When Execution Host Starts Up

6.3.1.25.i Event when Execution Host Starts or Receives HUP

When an execution host starts up or receives a HUP, an exechost_startup hook can:

- Create vnodes on local host
- Create custom resources for vnodes
- Offline vnodes that are not ready for use
- Return vnodes to use that have been previously offlined
- Modify the attributes and resources of the vnodes managed by the local MoM

6.3.1.25.ii The exechost_startup Hook Interface

This event type is pbs.HOOK_EVENT_EXECHOST_STARTUP.

The exechost_startup hook runs on a MoM host every time its MoM starts up, or when a Linux `pbs_mom` receives a SIGHUP signal. This hook executes after MoM loads `pbs.conf` values, reads `mom_priv/config` values, and runs platform-specific initializations, for example cpuset initialization, including topology data gathering. If there are Version 2 configuration files, this hook sets vnode definitions from those Version 2 configuration files.

The exechost_startup hook runs independently of jobs; it depends only on MoM startup and HUP.

A pbs.HOOK_EVENT_EXECHOST_STARTUP event has the following member, in addition to those listed in section 6.3.2, "Event Object Members", on page 116:

pbs.event().vnode_list[]

This is a dictionary of pbs.vnode objects, keyed by vnode name, listing the vnodes that are managed by the MoM where the hook runs. See section 6.3.2.24, "The Vnode List Event Member", on page 123 for information about using pbs.event().vnode_list[].

A pbs.HOOK_EVENT_EXECHOST_STARTUP event has the methods listed in section 6.15.2, "Methods Available in Events", on page 165.

On a call to pbs.event().accept() or pbs.event().reject(), vnode changes take effect, and MoM continues to run.

A call to pbs.event().reject(<message>) causes the following messages to appear in the MoM log:

```
"exechost_startup" request rejected by hook <hook_name>"
<message>
```

If the exechost_startup hook script encounters an unexpected error causing an unhandled exception:

- Vnode changes do not take effect
- MoM continues to run
- The following message appears at PBSEVENT_DEBUG2 in `mom_logs`:

```
"exechost_startup hook <hook_name> encountered an exception, request rejected"
```

If the exechost_startup hook script terminates due to a hook alarm, vnode changes do not take effect, MoM continues to run, and the following message appears at PBSEVENT_DEBUG2 in `mom_logs`:

```
"alarm call while running exechost_startup hook '<hook_name>', request rejected'
```

6.3.1.25.iii Advice on Using exechost_startup Hooks

- We recommend that your hook does not make changes unless the hook accepts its event. You do not want to have to back changes out upon a reject().
- For exceptions, we recommend that you catch them via `try... except` and accompany them with a call to pbs.event().reject().
- We recommend that before calling pbs.event().reject(), you set the vnodes managed by the local MoM offline with an accompanying comment. This stops jobs from being sent to the affected vnodes. For example:

```
vnlist = pbs.event().vnode_list
for v in vnlist.keys():
    vnlist[v].state = pbs.ND_OFFLINE
    vnlist[v].comment = "bad configuration"
pbs.event().reject("not accepting jobs")
```

6.3.1.26 exechost_periodic: Periodic Events on All Execution Hosts

6.3.1.26.i Periodic Events at Execution Hosts

Periodically, at each execution host, an exechost_periodic hook can:

- Set attributes and resources for any vnode managed by the MoM on the host where the hook runs. This means that an instance of a hook can affect more than one vnode only when the hook is running on a multi-vnode host.
- Set attributes or resources for each job managed by the local MoM.

6.3.1.26.ii The exechost_periodic Hook Interface

This event type is pbs.HOOK_EVENT_EXECHOST_PERIODIC.

The exechost_periodic hook runs periodically on all the MoM hosts in the complex.

The interval between calls to exechost_periodic hooks is specified in the freq hook attribute. See section 5.1.13, “Setting Hook Interval (Frequency)”, on page 40.

A pbs.HOOK_EVENT_EXECHOST_PERIODIC event has the following members, in addition to those listed in section 6.3.2, “Event Object Members”, on page 116:

pbs.event().vnode_list[]

This is a dictionary of pbs.vnode objects, keyed by vnode name, listing the vnodes that are managed by the MoM where the hook runs. See section 6.3.2.24, “The Vnode List Event Member”, on page 123 for information about using pbs.event().vnode_list[].

pbs.event().job_list[]

List of the pbs.job objects managed by the local MoM. This hook can set the attributes and resources for these jobs. See section 6.3.2.11, “Job List Event Member”, on page 120.

A pbs.HOOK_EVENT_EXECHOST_PERIODIC event has the methods listed in section 6.15.2, “Methods Available in Events”, on page 165.

A call to pbs.event().accept() or pbs.event().reject(<message>) causes any changes made to vnodes to take effect.

A call to pbs.event().reject(<message>) causes the following messages to appear in the MoM log:

```
"exechost_periodic" request rejected by hook <hook_name>"
<message>
```

The periodic hook continues to be periodically called whether or not there are errors in hook script execution or a call to the pbs.event().reject() action. To stop the hook from being called, either disable it or delete it:

```
#qmgr -c "s h <periodic hook> enabled=f"
#qmgr -c "d h <periodic hook>"
```

If the exechost_periodic hook script encounters an unexpected error causing an unhandled exception, or if the script terminates due to a hook alarm, all vnode changes, requests for host reboot or scheduler cycle restarts, do **not** take effect. In addition, one of the following messages appears in the MoM log at event class PBSEVENT_DEBUG2:

```
"exechost_periodic hook <hook_name> encountered an exception, request rejected"
"alarm call while running exechost_periodic hook '<hook_name>', request rejected"
```

6.3.1.26.iii Caveats for exechost_periodic Event Hooks

The order attribute is ignored for exechost_periodic hooks. It does **not** guarantee the execution order of a list of periodic hooks.

6.3.1.27 provision: Hook for Provisioning Vnodes

When a job requests provisioning of a vnode, a provision hook can cause a new AOE to be instantiated on the vnode. The provisioning hook reads the name of the vnode to be provisioned and the AOE to be instantiated, and runs a provisioning script.

See "Provisioning" on page 591 in the PBS Professional Administrator's Guide.

6.3.2 Event Object Members

Some event object members are hook attributes, and some exist as part of the event object but are not hook attributes. The following tables summarize the members for event objects, and show which event objects have access to each member, and whether the event hook can read and set the member. An "*r*" indicates read, an "*s*" indicates set, and an "*o*" indicates that this member can be set but the action has no effect. See Table 4-1, "Execution Event Hook Timing," on page 20 for more information about why some operations have no effect.

Table 6-26: Using Event Object Members in Job Events

Event Object Member	provision	queuejob	postqueuejob	movejob	modifyjob (before run)	runjob (on reject)	runjob (on accept)	jobobit	execjob_begin	execjob_prologue	execjob_launch	execjob_attach	execjob_postsuspend	execjob_preresume	execjob_preterm	execjob_epilogue	execjob_end
pbs.event().alarm	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---
pbs.event().argv[]	---	---	---	---	---	---	---	---	---	---	r, s	---	---	---	---	---	---
pbs.event().debug	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---
pbs.event().enabled	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---
pbs.event().env	---	---	---	---	---	---	---	---	---	---	r, s	---	---	---	---	---	---
pbs.event().fail_action	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---
pbs.event().freq	---	---	r, s	---	---	---	r, s	---	---	---	---	---	---	---	---	---	---
pbs.event().hook_name	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
pbs.event().hook_type	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
pbs.event().job	---	r, s	r, s	r, s	r, s	r, s	r, s	r, s	r, s	r, s	r	r	r	r	r, s	r, s	r, s
pbs.event().job_list (jobs)	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---
pbs.event().job_o	---	---	---	---	r	---	---	---	---	---	---	---	---	---	---	---	---
pbs.management	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---
pbs.event().order	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---
pbs.event().pid	---	---	---	---	---	---	---	---	---	---	---	r	---	---	---	---	---

Table 6-26: Using Event Object Members in Job Events

Event Object Member	provision	queuejob	postqueuejob	movejob	modifyjob (before run)	runjob (on reject)	runjob (on accept)	jobobit	execjob_begin	execjob_prologue	execjob_launch	execjob_attach	execjob_postsuspend	execjob_preresume	execjob_preterm	execjob_epilogue	execjob_end
pbs.event().progname	---	---	---	---	---	---	---	---	---	---	r, s	---	---	---	---	---	---
pbs.event().requestor	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
pbs.event().requestor_host	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
pbs.event().resv	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---
pbs.event().resv_o	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---
pbs.event().src_queue	---	---	---	r	---	---	---	---	---	---	---	---	---	---	---	---	---
pbs.event().type	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
pbs.event().user	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---
pbs.event().vnode	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---
pbs.event().vnode_list[]	---	---	---	---	---	---	---	---	r, s	r, s	r, s	r	r, s	r, s	r, s	r, s	r, s
pbs.event().vnode_list_fail[]	---	---	---	---	---	---	---	---	---	r	r	---	---	---	---	---	---
pbs.event().vnode_o	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

Table 6-27: Using Event Object Members in Reservation and Other Non-job Events

Event Object Member	resvsub	resv_confirm	modifyresv	resv_begin	resv_end	management	periodic	modifyvnode	exechost_periodic	exechost_startup
pbs.event().alarm	---	---	---	---	---	---	---	---	---	---
pbs.event().argv[]	---	---	---	---	---	---	---	---	---	---
pbs.event().debug	---	---	---	---	---	---	---	---	---	---
pbs.event().enabled	---	---	---	---	---	---	---	---	---	---
pbs.event().env	---	---	---	---	---	---	---	---	---	---
pbs.event().fail_action	---	---	---	---	---	---	---	---	---	---
pbs.event().freq	---	---	---	---	---	---	---	---	---	---
pbs.event().hook_name	r	r	r	r	r	---	---	r	r	r
pbs.event().hook_type	r	r	r	r	r	---	---	r	r	r
pbs.event().job	---	---	---	---	---	---	---	---	---	---
pbs.event().job_list (jobs)	---	---	---	---	---	---	---	---	r, s	---
pbs.event().job_o	---	---	---	---	---	---	---	---	---	---
pbs.management	---	---	---	---	---	---	---	---	---	---
pbs.event().order	---	---	---	---	---	---	---	---	---	---
pbs.event().pid	---	---	---	---	---	---	---	---	---	---
pbs.event().progname	---	---	---	---	---	---	---	---	---	---
pbs.event().requestor	r	r	r	r	r	---	---	---	r	r
pbs.event().requestor_host	r	r	r	r	r	---	---	---	r	r

Table 6-27: Using Event Object Members in Reservation and Other Non-job Events

Event Object Member	resvsub	resv_confirm	modifyresv	resv_begin	resv_end	management	periodic	modifyvnode	exechost_periodic	exechost_startup
pbs.event().resv	table 5-10	table 5-10	table 5-10	table 5-10	table 5-10	---	---	---	---	---
pbs.event().resv_o	---	---	table 5-10	---	---	---	---	---	---	---
pbs.event().src_queue	---	---	---	---	---	---	---	---	---	---
pbs.event().type	r	r	r	r	r	---	---	---	r	r
pbs.event().user	---	---	---	---	---	---	---	---	---	---
pbs.event().vnode	---	---	---	---	---	---	---	r	---	---
pbs.event().vnode_list[]	---	---	---	---	---	---	---	---	r, s	r, s
pbs.event().vnode_list_fail[]	---	---	---	---	---	---	---	---	---	---
pbs.event().vnode_o	---	---	---	---	---	---	---	r	---	---

An event object (an object returned by pbs.event()) has one or more of the following members:

6.3.2.1 Hook Alarm Event Member

pbs.event().alarm

Hook attribute. Number of seconds to allow a hook to run before the hook times out. Must be greater than zero. See "alarm" on page 349 of the PBS Professional Reference Guide.

Type: *Integer*

6.3.2.2 Job Program Arguments Event Member

pbs.event().argv[]

The list of arguments to be passed to the job script. The arguments can be modified in an execjob_launch hook.

Type: *Python list of strings*

To add another argument to the argument list, append it:

```
pbs.event().argv.append(<new_argument>)
```

To clear out existing argv[] entries and supply a new set of arguments, use the following:

```
pbs.event().argv = []      (sets argv[] to empty list)
pbs.event().argv.append(<arg0>)
pbs.event().argv.append(<arg1>)
…
pbs.event().argv.append(<argN>)
```

On Windows, where backslashes may appear in pathnames, escape each backslash with another backslash, or use the raw ('r') operator to form the string. Both of the following work:

```
e = pbs.event()
e.progname = "C:\\Program Files\\PBS Pro\\exec\\bin\\pbsnodes.exe"
e.progname = r"C:\Program Files\PBS Pro\exec\bin\pbsnodes.exe"
```

See section 6.3.3, "Event Object Member Caveats", on page 125.

To log the arguments to the program, and update some of them:

```
for a in pbs.event().argv:
    pbs.logmsg(pbs.LOG_DEBUG, "a=%s" % (a,))

argv = pbs.event().argv
argv[1] = "beta"
argv[3] = "gamma"
```

6.3.2.3 Hook Debug Behavior Indicator Event Member

pbs.event().debug

Hook attribute. Specifies whether or not the hook produces debugging files under PBS_HOME/server_priv/hooks/tmp or PBS_HOME/mom_priv/hooks/tmp. Files are named *hook_<hook event>_<hook name>_<unique ID>.in*, *.data*, and *.out*. See "Producing Files for Debugging" on page 183 in the PBS Professional Hooks Guide, and "debug" on page 349 of the PBS Professional Reference Guide.

Type: *Boolean*

6.3.2.4 Hook Enable or Disable Event Member

pbs.event().enabled

Hook attribute. Specifies whether or not the hook is enabled. See "enabled" on page 349 of the PBS Professional Reference Guide.

Type: *Boolean*

6.3.2.5 Job Environment Event Member

pbs.event().env

The job's environment. Can be modified in an execjob_launch hook.

Type: dictionary of *environment "<variable>=<value>"* entries, with <*variable*> serving as the dictionary key.

To modify a particular environment entry:

```
pbs.event().env[<variable>] = <value>
```

To add more entries to the env[] dictionary:

```
pbs.event().env[<new_var>] = <value>
```

To clear out existing env[] entries and specify a new environment:

```
pbs.event().env = pbs.pbs_env()
pbs.event().env[<var1>] = <value1>
pbs.event().env[<var2>] = <value2>
…
pbs.event[<varN>.] = <valueN>
```

To unset an existing environment variable:

```
pbs.event().env[<var>] = None
```

To embed a comma in an environment variable, escape the value with single quotes:

```
pbs.event().env[<var>] = '"<value>"'
```

On Windows, where backslashes appear in pathnames, either escape the backslash with another backslash, or use the raw ('r') operator to form the string. Both of the following examples will work:

```
e = pbs.event()
e.progname = "C:\\Program Files\\PBS Pro\\exec\\bin\\pbsnodes.exe"
e.progname = r"C:\Program Files\PBS Pro\exec\bin\pbsnodes.exe"
```

See section 6.3.3, "Event Object Member Caveats", on page 125.

Example 6-2: To log the contents of a job's environment variables:

```
for v in pbs.event().env.keys():
    e = pbs.event().env[v]
    pbs.logmsg(pbs.LOG_DEBUG, "env[%s]=%s" % (v,e))
```

6.3.2.6 Failure Action Event Member

pbs.event().fail_action

Hook attribute. Action to take on hook failure or on subsequent successful execution. See "fail_action" on page 351 of the PBS Professional Reference Guide.

6.3.2.7 Frequency Event Member

pbs.event().freq

Hook attribute. Frequency at which to run hook. See "freq" on page 351 of the PBS Professional Reference Guide.

6.3.2.8 Hook Name Event Member

pbs.event().hook_name

Name of the hook being executed.

Type: *str*

6.3.2.9 Hook Type Event Member

pbs.event().hook_type

The type of the hook. The only valid value is "*site*". Represents the Type hook attribute.

Type: *str*

6.3.2.10 Job Event Member

pbs.event().job

The job that triggered the event. A pbs.job object. See section 6.6, "Job Objects", on page 132.

6.3.2.11 Job List Event Member

pbs.event().job_list

The list of jobs managed by the local MoM. Each job is a pbs.job, described in section 6.6, "Job Objects", on page 132.

For a list of settable job attributes, see section 5.2.4.15, “Tables: Reading & Setting Job Attributes in Hooks”, on page 56.

For a list of settable job resources, see section 5.2.4.18, “Tables: Reading & Setting Built-in Job Resources in Hooks”, on page 64.

Type: dictionary of pbs.job objects

To print the jobs in the list:

```
for k in pbs.event().job_list.keys():
    print pbs.event().job_list[k]
```

To set a job attribute or resource for all jobs in the list:

```
for k in pbs.event().job_list.keys():
    pbs.event().job_list[k].<attribute> = <value>
```

In an exechost_periodic hook, attributes are set after the hook ends in a call to pbs.event().accept() or pbs.event().reject(), but not when the hook encounters an uncaught exception or hits an alarm call.

In an exechost_periodic hook, you can flag a job to be requeued using rerun() or deleted using delete() when the server is notified that the job has terminated.

Example 6-3: Rerun all jobs in this MoM's job list:

```
% cat period.py
import pbs
for k in pbs.event().job_list.keys():
    pbs.event().job_list[k].rerun()
```

6.3.2.12 Original Job Event Member

pbs.event().job_o

This is a pbs.job object representing the original job, before the job was modified via `qalter`. All resources and attributes are populated.

See section 6.6, “Job Objects”, on page 132.

6.3.2.13 Order Event Member

pbs.event().order

Hook attribute. Order in which to run hook. See “order” on page 351 of the PBS Professional Reference Guide.

6.3.2.14 Process ID Event Member

pbs.event().pid

The process ID of a task belonging to a job.

Type: *int*

6.3.2.15 Job Executable Event Member

pbs.event().progname

The path to the job shell or executable. This is settable in an execjob_launch hook as follows:

```
pbs.event().progname = "<path_to_the_script>"
```

When setting the value, specify the full path. Otherwise, the path may not be found, and the shell or executable may not run.

Type: *str*

6.3.2.16 Requestor Event Member

pbs.event().requestor

The requestor of the event.

PBS daemons can request actions. If a daemon requests an action, the requestor member contains one of "*PBS_Server*", "*Scheduler*", or "*pbs_mom*". If the requestor is root, the member contains "*root*".

For Windows systems, if the requestor is the administrator, the member contains the account name of the administrator.

Type: *str*

6.3.2.17 Requestor Host Event Member

pbs.event().requestor_host

The name of the host from which the event was requested.

Type: *str*

6.3.2.18 Reservation Event Member

pbs.event().resv

A reservation object being requested in a reservation event. For a modifyresv event, this object contains not the reservation, but a list of requested changes. See section 6.9, “Reservation Objects”, on page 144.

6.3.2.19 Reservation, Before Changes, Event Member

pbs.event().resv_o

A reservation object that represents the reservation being requested in a reservation event, before changes. See section 6.9, “Reservation Objects”, on page 144.

6.3.2.20 Source Queue Event Member

pbs.event().src_queue

The pbs.queue object representing the original queue where pbs.event().job came from.

See section 6.5, “Queue Objects”, on page 131.

6.3.2.21 Event Type Event Member

pbs.event().type

Hook attribute. The event type, for example, queuejob or movejob. Valid values: one of the PBS event type constants listed in section 6.3.1, “Event Types”, on page 87. See “type” on page 351 of the PBS Professional Reference Guide.

Type: A PBS event type constant, such as pbs.HOOK_EVENT_QUEUEJOB, pbs.HOOK_EVENT_RESVSUB

6.3.2.22 Event User Event Member

pbs.event().user

Hook attribute. The username under which the hook executes. See “user” on page 351 of the PBS Professional Reference Guide.

Valid values: *pbsadmin*, *pbsuser*.

pbsadmin

On Linux, this is root. On Windows, this is simply a substitute for the PBS service account; it is not the name of the PBS service account.

pbsuser

The hook runs under the account of the job owner, which is the value of the euser job attribute. Can be used for execjob_prologue, execjob_epilogue, execjob_preterm events only.

Default value: *pbsadmin*

Type: *String*, *str*

6.3.2.23 The Current and Original Vnode Event Members

pbs.event().vnode

pbs.event().vnode_o

The modifyvnode event hook has read-only access to the pbs.event().vnode object, which represents the vnode after a state change has occurred, and the pbs.event().vnode_o object, which represents the vnode before the state change occurred.

6.3.2.24 The Vnode List Event Member

pbs.event().vnode_list[]

Execution event hooks have access to the list of vnodes assigned to the job. Periodic event hooks have access to the list of vnodes managed by the local MoM. The exechost_startup and execjob_launch hooks can create and modify the vnodes managed by the local MoM.

When a vnode is in such a list, the hook has access to the attributes and resources of that vnode.

We list which hooks can operate on vnode_list[] in Table 6-26, “Using Event Object Members in Job Events,” on page 116 and Table 6-27, “Using Event Object Members in Reservation and Other Non-job Events,” on page 117.

We list which hooks can read and/or set each vnode attribute in Table 5-8, “Vnode Attributes Readable & Settable via Job Events,” on page 61 and Table 5-9, “Vnode Attributes Readable & Settable via Reservation & Other Non-job Events,” on page 62.

We list which hooks can read and/or set each vnode resource in Table 5-13, “Vnode Resources Readable & Settable by Hooks via Job Events,” on page 66 and Table 5-14, “Vnode Resources Readable & Settable by Hooks via Reservation & Other Non-job Events,” on page 67.

When this list is retrieved through an execution event, it is associated with a job, and only vnodes assigned to the job have attributes, resources_available, resources_assigned.ncpus, and resources_assigned.mem filled in; on other vnodes, only pbs.vnode().name is available. See section 6.10, “Vnode Objects”, on page 146.

You can use an exechost_startup or execjob_launch hook to create vnodes on the host where the hook runs:

```
pbs.event().vnode_list[<new vnode>] = pbs.vnode(<new vnode name>)
```

If you want to use an execjob_* hook to manipulate a vnode that is not assigned to the job, but is still managed by the hook's MoM, you must first instantiate the object for that vnode with the name of the new vnode:

```
pbs.event().vnode_list[<new vnode>] = pbs.vnode(<new vnode name>)
```

Once you have instantiated your new vnode (which must still be managed by your hook's MoM), you can operate on it as shown here:

- To list all vnodes:

```
for v in pbs.event().vnode_list.keys():
    pbs.logmsg(pbs.LOG_DEBUG, "found vnode %s" % (pbs.event().vnode_list[v].name))
```

- To get the parent vnode managed by the local MoM, use the pbs.get_local_nodename() function to return the local parent vnode name where this hook is executing, and then use pbs.event().vnode_list[<local parent vnode name>].

```
local_node = pbs.get_local_nodename()
```

  If the parent vnode name used on the server when adding this host to the complex is different from that returned by `gethostname()` on the host, use PBS_MOM_NODE_NAME in the hosts's `/etc/pbs.conf` file to make the parent node name consistent with the one used by the server.

- To find the other vnodes managed by the hook's MoM:

  a. Query the server for its list of vnodes:

```
pbs.server().vnodes()
```

  b. Look in the Mom attribute in the resulting list of vnodes for a match to the output of:

```
pbs.get_local_nodename()
```

- Setting and unsetting attributes and resources:

  To set the attributes and resources for a particular vnode:

  pbs.event().vnode_list[<vnode name>].<attribute> = <value>
  pbs.event().vnode_list[<vnode name>].<resources_available>["<resource name>"] = <value>

  You can unset a resource value by specifying "*None*" as its value:

  pbs.event().vnode_list[<vnode_name>].resources_available["<resource name>"] = None

  Resource names and string values must be quoted.

  For details and examples, see section 5.2.4.11, “Setting and Unsetting Vnode Resources and Attributes”, on page 49.

- You can add new custom host-level, non-consumable resources and their values to resources_available for a vnode:

  vnode_list[<vnode name>].resources_available[<new resource>] = <value>

  For details and examples, see section 5.2.7, “Adding Custom Host-level Resources”, on page 69.

You cannot modify a vnode that is managed by a different MoM from where the hook is running. If you try to do this, the following error message appears in the server's log at log event class PBSEVENT_DEBUG2:

```
"<node_host_name>; Not allowed to update <vnode name>, as it is owned by a different mom"
```

A hook that runs as "*pbsuser*" (execjob_prologue, execjob_epilogue, execjob_preterm) is not allowed to manipulate pbs.event().vnode_list[], unless the executing user is a PBS Manager or Operator. If a hook running as an unprivileged user tries to change pbs.event().vnode_list[], the following error message appears in the server's log at log event class PBSEVENT_DEBUG2:

```
"<node_host_name>; Not allowed to update vnodes or to request scheduler restart cycle, if run as
    a non-manager/operator user"
```

6.3.2.25 The Failed Vnode List Event Member

pbs.event().vnode_list_fail[]

For each execjob_prologue and execjob_launch event, PBS records the list of vnodes, with their assigned resources, that are marked as bad by MoM. This list can include those vnodes from sister MoMs that failed to join the job, that rejected an execjob_begin hook or execjob_prologue hook request, or that encountered a communication error while the primary MoM was polling the sister MoM host. PBS records this list in the pbs.event().vnode_list_fail[] hook parameter. For how vnodes are marked as failed, see "Checking Vnodes and Marking Them as Failed" on page 406 of the PBS Professional Administrator's Guide.

Type: *dict* (dictionary of pbs.vnode objects keyed by vnode name)

6.3.3 Event Object Member Caveats

6.3.3.1 Modifying progname or argv[] Under Windows

On Windows, in a multi-vnoded job, be careful modifying pbs.event().progname and pbs.event().argv[] parameters; some values are tacked on by pbs_mom and are required. For example, if a multi-vnode job has in its script:

```
pbsdsh -n 1 cmd.exe /C echo hi
```

This causes an installed execjob_launch hook to execute on the sister MoM specified at node index '*1*'. The execjob_launch hook sees:

```
pbs.event().progname=cmd.exe

pbs.event().argv[0]=cmd.exe
pbs.event().argv[1]=/c
pbs.event().argv[2]=C:/PROGRA~1/PBSPRO~1/exec/sbin/mom_open_demux.exe
pbs.event().argv[3]=174.host1
pbs.event().argv[5]=cmd.exe
pbs.event().argv[6]=/C
pbs.event().argv[7]=echo
pbs.event().argv[8]=hi
```

It is important not to modify pbs.event().progname and pbs.event().argv[0],...,pbs.event().argv[3]. These are automatically added by pbs_mom for execution and collecting output.

You can modify pbs.event().argv[] values starting at index *5*, and you can use pbs.event().argv.extend() to add more arguments. Here we modify values for indices *5* through *8*, and add pbs.event().argv[9], making it "*hello*":

```
pbs.event().argv[5] = "pbsnodes.exe"
pbs.event().argv[6] = "-a"
pbs.event().argv[7] = ""
pbs.event().argv[8] = ""
pbs.event().argv.extend(["hello"])
```

6.3.4 Event-only Methods

6.3.4.1 Event Method for Accepting Event

pbs.event().accept()

Terminates hook execution and causes PBS to perform the associated action.

6.3.4.2 Event Method for Rejecting Event

pbs.event().reject()

pbs.event().reject(["<error message>"][,<error code>])

Terminates hook execution and instructs PBS to not perform the associated action. If the <message> argument is given, it is shown in the appropriate PBS daemon log, and in the `stderr` of the PBS command that caused this event to take place.

By default, pbs.event().reject() returns *255*. To return an error code other than *255*, specify a value between *2* and *255* in the optional <error code>.

6.3.5 Event Object Method Caveats

pbs.event().accept() terminates hook execution by throwing a SystemExit exception. So if hook content appears in a `try…except` clause that has no arguments to the `except` clause, always add the following to treat SystemExit as a normal occurrence:

```
except SystemExit:
    pass
```

See section 5.3.7.1, “Treat SystemExit as a Normal Occurrence”, on page 76.

6.3.6 Examples of Using Event Objects

Example 6-4: Inside a hook script, create a PBS event object:

```
e = pbs.event()
```

Example 6-5: Get the event type:

```
type = e.type
```

Example 6-6: Get the user who requested the event action:

```
who = e.requestor
```

Example 6-7: Get the host where the request came from:

```
host = e.requestor_host
```

Example 6-8: The event type is pbs.HOOK_EVENT_QUEUEJOB. Get the number of CPUs requested for the job being queued:

```
j = e.job
res = j.Resource_List["ncpus"]
```

Example 6-9: Reset the number of CPUs requested by the job:

```
j.Resource_List["ncpus"] = 1
```

Example 6-10: The event type is pbs.HOOK_EVENT_MOVEJOB. Get the request parameters:

```
j = e.job
q = j.queue
```

Example 6-11: Accept an event request:

```
e.accept()
```

Example 6-12: Reject an event request:

```
e.reject("Can't set interactive attribute")
```

Example 6-13: Put a job into a wait state and requeue the job in 3600 seconds (1 hour):

```
import time
...
j.Execution_Time = time.time() + 3600
```

Example 6-14: Put a hold on a job:

```
j = pbs.event().job
j.Hold_Types = pbs.hold_types("u")
j.Hold_Types = pbs.hold_types("uo")
j.Hold_Types += pbs.hold_types("s")
```

or

```
j.Hold_Types = pbs.hold_types("<hold_list>")
```

Example 6-15: Release a hold on a job:

```
j.Hold_Types -= pbs.hold_types("un")
j.Hold_Types -= pbs.hold_types("sp")
j.Hold_Types -= pbs.hold_types("o")
```

or

```
j.Hold_Types -= pbs.hold_types("<hold_list>")
```

6.4 Server Objects

pbs.server

This object represents a PBS server. This object can either represent the local server, or be just a coding construct, not representing an actual server. If it represents the local server, you can read but cannot set its attributes. If it is just a coding construct that does not represent an actual server, you can set its attributes. **You cannot alter the PBS server.** If this server object represents the PBS server, it is the server at which the triggering event is taking place, and at which the hook is executing. The only PBS server available to hooks is the local server.

s = pbs.server(["<name>"])

Creates an instance of a PBS server object. If *<name>* is not specified, the object represents the default server.

You can use pbs.server() to retrieve server, queue, job, vnode, and reservation information, and pass it to a hook script. You **cannot** set attributes or resources for objects that are retrieved through the server via pbs.server().

6.4.1 Server Object Members

Some server object members are server attributes, and some are not. A pbs.server has the following members:

6.4.1.1 Server Name Member

pbs.server().name

The server hostname.

Example: `myhost.mydomain.com`

This member is read-only.

Python type: *str*

6.4.1.2 Server Attribute Members

pbs.server().<attribute name>

The PBS server attribute named *<attribute name>*. The pbs.server object has a member to represent each server attribute, spelled exactly like the attribute. For information about using attributes, see section 5.2.4, "Using Attributes and Resources in Hooks", on page 45.

Server attributes are listed in "Server Attributes" on page 281 of the PBS Professional Reference Guide. Attribute creation methods are described in section 6.15.3, "PBS Types and Their Methods", on page 168.

6.4.1.2.i Server State Attribute Member

pbs.server().server_state

The server_state server attribute. It can take one of the following values, represented by constant objects:

Table 6-28: Server State Constant Objects

Object	State
pbs.SV_STATE_IDLE	*Idle*
pbs.SV_STATE_ACTIVE	*Scheduling*
pbs.SV_STATE_HOT	*Hot_Start*

Table 6-28: Server State Constant Objects

Object	State
pbs.SV_STATE_SHUTDEL	*Terminating, Delayed*
pbs.SV_STATE_SHUTIMM	*Terminating*
pbs.SV_STATE_SHUTSIG	*Terminating*

6.4.2 Setting Server Object Members

If the server object does not represent the PBS server, you can set, but not unset, server object members. If a server object does represent the PBS server, you cannot set values for object members. To set the value for the server attribute named *<attribute name>* to *<attribute value>*, where *s* is an instance of pbs.server:

```
s.<attribute name> = <attribute value>
```

6.4.3 Examples of Using Server Object Members

```
s = pbs.server()
```

Example 6-16: Get server name:

```
name = s.name
```

Example 6-17: Get the value of the server attribute pbs_license_min:

```
min = s.pbs_license_min
```

6.4.4 Server Object Methods

6.4.4.1 Method to Return Job

pbs.server().job('<job ID>')

Returns a pbs.job object for the job with ID <*id*>, residing on the local server. Returns *None* if the job with ID <*id*> does not exist at the server. See section 6.6, "Job Objects", on page 132.

6.4.4.2 Method to Return Job Iterator

pbs.server().jobs()

Returns a Python iterator that iterates over a list of pbs.job objects residing on the local server. Returns an empty iterator if no jobs exist on the local server. See section 6.6, "Job Objects", on page 132.

Example:

```
for j in s.jobs():
   pbs.logmsg(pbs.LOG_DEBUG, "found job %s" % (j.id))
```

6.4.4.3 Method to Return Queue

pbs.server().queue("<queue_name>")

Returns a pbs.queue object representing the queue named *<queue name>* that is managed by the local server. See section 6.5, "Queue Objects", on page 131.

A value of *None* is returned if the queue named *<queue_name>* does not exist at the local server.

6.4.4.4 Method to Return Queue Iterator

pbs.server().queues()

Returns a Python iterator that iterates over a list of queue objects managed by the the local server. Returns an empty iterator if no queues exist at the local server. See section 6.5, "Queue Objects", on page 131.

6.4.4.5 Method to Return Reservation

pbs.server().resv("<reservation ID>")

Returns a pbs.resv object for <*reservation ID*> on the local server. Returns *None* if <*reservation ID*> does not exist. See section 6.9, "Reservation Objects", on page 144.

6.4.4.6 Method to Return Reservation Iterator

pbs.server().resvs()

Returns a Python iterator that iterates over a list of pbs.resv objects residing on the local server. Returns an empty iterator if no reservations exist at the local server. See section 6.9, "Reservation Objects", on page 144.

6.4.4.7 Method to Restart Scheduler Cycle

pbs.server().scheduler_restart_cycle()

This directs the current PBS server to tell the scheduler to restart its scheduling cycle.

A hook with its user attribute set to *pbsuser* cannot successfully invoke pbs.scheduler_restart_cycle(), unless the hook's executing user is a PBS Manager or Operator. If this is attempted, the scheduler is not restarted, and the following message appears at log event class PBSEVENT_DEBUG2 in the MoM logs:

```
"<node_host_name>;Not allowed to update vnodes or to request scheduler_restart_cycle, if run as a
    non-manager/operator user"
```

6.4.4.8 Method to Return Named Vnode

pbs.server().vnode("<vnode name>")

Returns a pbs.vnode object representing the vnode with name <*vnode name*> that is managed by the current server.

Returns *None* if <*vnode name*> does not exist.

6.4.4.9 Method to Return Vnode List

pbs.server().vnodes()

Returns a list of pbs.vnode objects managed by current server.

Returns an empty iterator if no vnodes exist at the local server.

Example:

```
for vn in s.vnodes():
    pbs.logmsg(pbs.LOG_DEBUG, "found vn %s" % (vn.name))
```

6.5 Queue Objects

pbs.queue

A pbs.queue object represents a PBS queue. This object can either represent an actual PBS queue, or be just a coding construct, not representing an actual queue. If it is just a coding construct, you can set its attributes. If it represents an actual queue, you can read but cannot set its attributes. **You cannot set the attributes of any actual queue in any hook**.

To get information about a particular queue with name <*name*>, you must go through the associated server. Use:

```
q = pbs.server().queue("<name>")
```

To get a list of queues from the server:

```
pbs.server().queues()
```

6.5.1 Queue Object Members

Some queue object members are queue attributes, and some are not.

6.5.1.1 Queue Object Name Member

queue.name

A queue.name is the name of that queue.

This member is read-only.

Python type: *str*

6.5.1.2 Queue Object Attribute Members

A pbs.queue has a member representing each of its attributes. Each member that is not a *string*, *int*, *bool*, *long*, or *float* has a corresponding creation method; see section 6.15.3, “PBS Types and Their Methods”, on page 168. See section 5.2.4, “Using Attributes and Resources in Hooks”, on page 45.

queue.<attribute name>

The queue attribute named <*attribute name*>. Queue attributes are listed in “Queue Attributes” on page 311 of the PBS Professional Reference Guide.

Example 6-18: Get the queue object representing the queue *workq*, and its Priority value:

```
q = s.queue("workq")
prio = q.Priority
```

6.5.1.3 Setting Queue Object Attributes

You can set or unset queue object attributes for queue objects that **don't** represent an actual queue. To set the value of a queue object attribute named **<*attribute name*>**:

```
pbs.queue.<attribute name> = <attribute value>
```

You cannot set or unset attributes for an actual queue.

6.5.2 Queue Object Methods

6.5.2.1 Method to Return Job

queue.job()

pbs.queue.job("<job ID>")

Returns a pbs.job object representing PBS job with ID *<job ID>*. This job must be residing on the queue. Returns *None* if the job with the specified job ID does not exist, or if the job is not in the queue. See section 6.6, "Job Objects", on page 132.

6.5.2.2 Method to Return Job Iterator

queue.jobs()

Returns a Python iterator that iterates over a list of pbs.job objects representing the jobs on the queue. Returns an empty iterator if no jobs exist on the queue. See section 6.6, "Job Objects", on page 132.

Example:

```
for j in pbs.server().queue("workq").jobs():
    pbs.logmsg(pbs.LOG_DEBUG, "found job %s" % (j.id))
```

6.5.3 Queue Type Constant Objects

Queue types are represented by constant objects. The pbs.queue.queue_type member represents the type of the queue. It can take on the following values:

Table 6-29: Queue Type Constant Objects

Object	Queue Type
pbs.QTYPE_EXECUTION	*Execution*
pbs.QTYPE_ROUTE	*Route*

6.6 Job Objects

pbs.job

A pbs.job object represents a PBS job.

You can retrieve the job object either through an associated event or through the server. The job object represents one of the following, depending on how it is retrieved:

- The PBS job associated with the event that triggers the hook. To get the job associated with the current event, go through the event that triggered the hook:

  pbs.event().job

  A call to pbs.event().job can return only the job associated with the current event.

  When you get a job using pbs.event().job, the hook can read and set the job attributes and resources listed in Table 5-6, "Job Attributes Readable & Settable via Job Events," on page 56 and Table 5-11, "Built-in Job Resources Readable & Settable by Hooks via Job Events," on page 64.

- A job at the server at which the hook is executing. To get a particular job with ID *<id>*, go through the server:

pbs.server().job("<job ID>")

When you get a job using pbs.server().job("<job ID>"), the hook can read all job attributes and resources, but can set none.

- To get a list of jobs at the server:

  pbs.server().jobs()

For information about a list of jobs visible through events, see section 6.3.2.11, "Job List Event Member", on page 120 and section 6-26, "Using Event Object Members in Job Events", on page 116 for the events that can use this list.

All job objects have the same members and methods. Each hook can read or set different attributes and resources. We describe what each type of hook can do in section 6.3, "Events", on page 86.

If you use a hook to make a change to a job, that change is visible to all PBS daemons.

6.6.1 Job Object Members

6.6.1.1 Job ID Member

job.id

The PBS job ID.

Read-only.

Python type: *str*

6.6.1.2 Job Attribute Members

A pbs.job object has a member to represent each job attribute. Each one is spelled exactly like the corresponding attribute. We list job object members here that require creation methods, require special treatment, or that are not job attributes. All job attribute members that are not listed here are defined this way:

job.<attribute name>

The type of the attribute is given in the attribute description, in "Job Attributes" on page 327 of the PBS Professional Reference Guide.

For information about using job attributes in hooks, see section 5.2.4, "Using Attributes and Resources in Hooks", on page 45.

We list the job resources that can be read and set via an event in each kind of hook in Table 5-11, "Built-in Job Resources Readable & Settable by Hooks via Job Events," on page 64 and Table 5-12, "Built-in Job Resources Readable & Settable by Hooks via Reservation & Other Non-job Events," on page 65.

We list the vnode resources that can be read and set via an event in each kind of hook in Table 5-13, "Vnode Resources Readable & Settable by Hooks via Job Events," on page 66 and Table 5-14, "Vnode Resources Readable & Settable by Hooks via Reservation & Other Non-job Events," on page 67.

6.6.1.2.i Job accrue_type Attribute Member

job.accrue_type

Represents the job's accrue_type attribute. Represented as a Python int. This member can take the following values:

Table 6-30: Values for the accrue_type Member

Integer Value	Name
0	*initial_time*
1	*ineligible_time*
2	*eligible_time*
3	*run_time*

6.6.1.2.ii Job array_indices_submitted Attribute Member

job.array_indices_submitted

Job attribute. Python type: *range*

See section 6.15.3.21, “Method to Create or Set range Object”, on page 173.

6.6.1.2.iii Job Checkpoint Attribute Member

job.Checkpoint

Job attribute. Python type: *pbs.checkpoint*

See section 6.15.3.3, “Method to Create or Set Checkpoint String”, on page 168.

6.6.1.2.iv Job depend Attribute Member

job.depend

Job attribute. Python type: *pbs.depend*

See section 6.15.3.4, “Method to Create or Set Dependency Object”, on page 169.

6.6.1.2.v Job Execution_Time Attribute Member

job.Execution_Time

Job attribute. Time when the current job is eligible to run. Syntax:

job.Execution_Time = time.mktime([<YY>, <MM>, <DD>, <HH>, <MM>, <SS>, <WEEKDAY>, <YEARDAY> <ISDST>])

For example, the following sets a job's Execution_Time to: *March 1, 2012 at 09:00 am*:

```
job.Execution_Time = time.mktime([2012, 3, 1, 12, 9, 0, -1, -1, -1])
```

Python type: *int*

6.6.1.2.vi Job exec_host Attribute Member

job.exec_host

Job attribute. Python type: *pbs.exec_host*

See section 6.15.3.7, “Method to Create or Set exec_host Object”, on page 169.

6.6.1.2.vii Job exec_vnode Attribute Member

job.exec_vnode

Job attribute. Python type: *pbs.exec_vnode*

This complex object is described in section 6.7, "The exec_vnode Object", on page 142.

See also section 6.15.3.8, "Method to Create or Set exec_vnode Object", on page 170.

6.6.1.2.viii Job group_list Attribute Member

job.group_list

Job attribute. Python type: *pbs.group_list*

See section 6.15.3.9, "Method to Create or Set group_list Object", on page 170.

6.6.1.2.ix Job Hold_Types Attribute Member

job.Hold_Types

Job attribute. Python type: *pbs.hold_types*

See section 6.15.3.10, "Method to Create or Set hold_types Object", on page 170.

6.6.1.2.x Job job_state and substate Attribute Members

job.job_state

Job attribute. Represents the job's state. Can be compared to the constants representing job states.

Use job state constant objects to test the state of a job. For example:

```
e = pbs.event()
if e.job.job_state == pbs.JOB_STATE_RUNNING :
    e.accept()
```

The job_state member can take on any of the values listed here:

Table 6-31: Job State Objects

Numeric Value	Type	State	Description
0	pbs.JOB_STATE_TRANSIT	*T*	Job is in transition (being moved to a new location)
1	pbs.JOB_STATE_QUEUED	*Q*	Job is queued, eligible to run or be routed
2	pbs.JOB_STATE_HELD	*H*	Job is held.
3	pbs.JOB_STATE_WAITING	*W*	Job is waiting for its requested execution time to be reached, or the job's specified stagein request has failed for some reason.
4	pbs.JOB_STATE_RUNNING	*R*	Job is running
5	pbs.JOB_STATE_EXITING	*E*	Job is exiting after having run
6	pbs.JOB_STATE_EXPIRED	*X*	Subjobs only; subjob is finished (expired.)
7	pbs.JOB_STATE_BEGUN	*B*	Job arrays only: job array has started
8	pbs.JOB_STATE_MOVED	*M*	Job has been moved to another server

Table 6-31: Job State Objects

Numeric Value	Type	State	Description
9	pbs.JOB_STATE_FINISHED	*F*	Job is finished: job executed successfully, job was terminated while running, job execution failed, or job was deleted before execution
400	pbs.JOB_STATE_SUSPEND	*S*	Job is suspended by PBS so that a higher-priority job can run.
410	pbs.JOB_STATE_SUSPEND_USERACTIVE	*U*	Job is suspended due to workstation becoming busy

job.substate

Job attribute. Represents the job's substate. Can be compared to the constants representing job substates.

The substate member can take on any of the values listed here:

Table 6-32: Job Substate Objects

Numeric Value	Type	Description
-1	pbs.JOB_SUBSTATE_UNKNOWN	Substate is unknown
0	pbs.JOB_SUBSTATE_TRANSIN	Transit in, prior to waiting for commit
1	pbs.JOB_SUBSTATE_TRANSICM	Transit in, waiting for commit
2	pbs.JOB_SUBSTATE_TRNOUT	transiting job outbound, not ready to commit
3	pbs.JOB_SUBSTATE_TRNOUTCM	transiting outbound, ready to commit
10	pbs.JOB_SUBSTATE_QUEUED	Job queued and ready for scheduling
11	pbs.JOB_SUBSTATE_PRESTAGEIN	job queued, has files to stage in
13	pbs.JOB_SUBSTATE_SYNCRES	Job waiting on sync start ready
14	pbs.JOB_SUBSTATE_STAGEIN	job staging in files before waiting
15	pbs.JOB_SUBSTATE_STAGEGO	job staging in files before running
16	pbs.JOB_SUBSTATE_STAGECMP	job stage in complete
20	pbs.JOB_SUBSTATE_HELD	job held - user or operator
21	pbs.JOB_SUBSTATE_SYNCHOLD	job held waiting on sync regist
22	pbs.JOB_SUBSTATE_DEPNHOLD	job held - waiting on dependency
30	pbs.JOB_SUBSTATE_WAITING	Job waiting until user-specified execution time
37	pbs.JOB_SUBSTATE_STAGEFAIL	job held - file stage in failed
41	pbs.JOB_SUBSTATE_PRERUN	job sent to MoM to run
42	pbs.JOB_SUBSTATE_RUNNING	Running
43	pbs.JOB_SUBSTATE_SUSPEND	Suspended by Operator or Manager
45	pbs.JOB_SUBSTATE_SCHSUSP	Suspended by scheduler

Table 6-32: Job Substate Objects

Numeric Value	Type	Description
50	pbs.JOB_SUBSTATE_EXITING	Server received job obit
51	pbs.JOB_SUBSTATE_STAGEOUT	Staging out stdout/err and other files
52	pbs.JOB_SUBSTATE_STAGEDEL	Deleting stdout/err files and staged-in files
53	pbs.JOB_SUBSTATE_EXITED	MoM releasing resources
54	pbs.JOB_SUBSTATE_ABORT	Job is being aborted by server
56	pbs.JOB_SUBSTATE_KILLSIS	(Set by MoM) Mother Superior telling sisters to kill everything
57	pbs.JOB_SUBSTATE_RUNEPILOG	(Set by MoM) job epilogue running
58	pbs.JOB_SUBSTATE_OBIT	(Set by MoM) job obit notice sent
59	pbs.JOB_SUBSTATE_TERM	Waiting for site-defined job termination action script
60	pbs.JOB_SUBSTATE_RERUN	Job to be rerun, MoM sending stdout/stderr back to server
61	pbs.JOB_SUBSTATE_RERUN1	Job to be rerun, staging out files
62	pbs.JOB_SUBSTATE_RERUN2	Job to be rerun, deleting files
63	pbs.JOB_SUBSTATE_RERUN3	Job to be rerun, freeing resources
69	pbs.JOB_SUBSTATE_EXPIRED	subjob is gone
70	pbs.JOB_SUBSTATE_BEGUN	Array job has begun
71	pbs.JOB_SUBSTATE_PROVISION	Job is waiting for vnode(s) to be provisioned with requested AOE.
72	pbs.JOB_SUBSTATE_WAITING_JOIN_JOB	Waiting to join job
91	pbs.JOB_SUBSTATE_TERMINATED	Job is terminated
92	pbs.JOB_SUBSTATE_FINISHED	Job is finished
93	pbs.JOB_SUBSTATE_FAILED	Job failed
94	pbs.JOB_SUBSTATE_MOVED	Job was moved
153	pbs.JOB_SUBSTATE_DELJOB	(Set by MoM) Mother Superior waiting for delete ACK from sisters

6.6.1.2.xi Getting Human-readable Names for Job State and Substate Types

The pbs.REVERSE_JOB_STATE object is a Python dictionary of job states mapped to human-readable names, and the pbs.REVERSE_JOB_SUBSTATE object is a Python dictionary of job substates mapped to human-readable names. This is useful for logging job information. The type for a state is found in pbs.job.job_state, and the type for a substate is found in pbs.job.substate.

Syntax

<string> = pbs.REVERSE_JOB_STATE[<job state type>]

For example:

```
my_job_state_str = pbs.REVERSE_JOB_STATE[my_job.job_state]
```

or

<string> = pbs.REVERSE_JOB_STATE[pbs.<job state>]

For example:

```
my_job_state_str = pbs.REVERSE_JOB_STATE[pbs.JOB_STATE_RUNNING]
```

Example

Example 6-19: Printing a human-readable name for a pbs.JOB_STATE_RUNNING job state using the type:

If the job is my_job and the state is pbs.JOB_STATE_RUNNING:

```
print(pbs.REVERSE_JOB_STATE[my_job.job_state])
```

results in:

```
JOB_STATE_RUNNING
```

6.6.1.2.xii Job Join_Path Attribute Member

job.Join_Path

Job attribute. Python type: *pbs.join_path*

See section 6.15.3.12, “Method to Create or Set join_path Object”, on page 170.

6.6.1.2.xiii Job Keep_Files Attribute Member

job.Keep_Files

Job attribute. Python type: *pbs.keep_files*

See section 6.15.3.13, “Method to Create or Set keep_files Object”, on page 171.

6.6.1.2.xiv Job Mail_Points Attribute Member

job.Mail_Points

Job attribute. Python type: *pbs.mail_points*

See section 6.15.3.15, “Method to Create or Set mail_points Object”, on page 171.

6.6.1.2.xv Job Mail_Users Attribute Member

job.Mail_Users

Job attribute. Python type: *pbs.email_list*

See section 6.15.3.6, “Method to Create or Set Email List”, on page 169.

6.6.1.2.xvi Job Queue Attribute Member

job.queue

Job attribute. Python type: *pbs.queue*

6.6.1.2.xvii Job Resource_List Attribute Member

job.Resource_List[]

job.Resource_List["<resource name>"]

Job attribute. The job's Resource_List attribute.

Python type: dictionary: *Resource_List["<resource name>"]=<value>* where <*resource name*> is any built-in or custom resource

6.6.1.2.xviii Job resources_used Attribute Member

job.resources_used["<resource name>"]

Job attribute. The job's resources_used attribute, which lists the resources used by the job. See section 5.2.4, "Using Attributes and Resources in Hooks", on page 45.

Python type: dictionary: *resources_used["<resource name>"]=<value>* where <*resource name*> is any built-in or custom resource

6.6.1.2.xix Job resv Member

job.resv

If the job is in a reservation, the corresponding job object has a resv reservation member. See section 6.9, "Reservation Objects", on page 144.

6.6.1.2.xx Job run_count Attribute Member

job.run_count

Job attribute. Execution hooks must run with user = *pbsadmin* to reduce the value of this member. Execution hooks running with user = *pbsuser* cannot reduce the value of this member.

Python type: *int*

6.6.1.2.xxi Job stagein and stageout Attribute Members

job.stagein

job.stageout

Job attribute. Python type: *pbs.staging_list*

See section 6.15.3.27, "Method to Create or Set staging_list Object", on page 175.

6.6.1.2.xxii Job User_List Attribute Member

job.User_List

Job attribute. Python type: *pbs.user_list*

See section 6.15.3.29, "Method to Create or Set user_list Object", on page 176.

6.6.1.2.xxiii Job Variable_List Attribute Member

job.Variable_List[<variable>]

Job attribute. Holds the job's environment variables. Syntax:

job.Variable_List[<variable>] = <value>

Python type: dictionary: *Variable_List["<variable name>"]=<value>*

6.6.1.3 Setting Job Attributes

How you set a job attribute depends on the type of the attribute; those of type *str*, *int*, *bool*, *long*, and *float* can be set directly. Job attributes of other types require creation methods. Job attribute creation methods are listed in section 6.15.3, "PBS Types and Their Methods", on page 168.

To set job attributes and resources directly:

pbs.event().job.<attribute> = <value>

pbs.event().job.Resource_List["<resource name>"] = <value>

See section 5.2.4.3, "Determining Whether to Use Creation Method to Set Attribute or Resource", on page 46.

See section 5.2.4, "Using Attributes and Resources in Hooks", on page 45.

6.6.1.4 Examples of Using Job Object Members

Get the job's Priority value:

```
prio = job.Priority
```

Reset the Priority value of job *j*:

```
job.Priority = 5
```

Get the job's PBS_O_WORKDIR environment variable:

```
workdir = job.Variable_List["PBS_O_WORKDIR"]
```

6.6.2 Job Object Methods for Execution Hooks

Job objects have the following methods. Most methods are available in execjob_ hooks except for the execjob_launch hook, and in the exechost_periodic hook.

6.6.2.1 Job Object Method to Report Checkpoint

job.is_checkpointed()

Returns a Python bool value which is *True* if the job was checkpointed under the control of the PBS MoM.

For example, you could use this in an execjob_epilogue hook, where the hook writer directs the job to be requeued if the job was checkpointed under the control of PBS:

```
# cat epi.py
import pbs
If pbs.event().job.is_checkpointed():
    pbs.event().job.rerun()
    pbs.event().reject("job to be requeued")
# qmgr -c "create hook epi event=execjob_epilogue"
# qmgr - c "import hook epi application/x-python default epi.py"
```

6.6.2.2 Job Object Method to Report Execution Host Role

job.in_ms_mom()

Returns a Python bool value. Returns *True* if this job object is running on the primary execution host.

6.6.2.3 Job Object Method to Delete Job

job.delete()

When this method is used in an execution hook, the job is flagged at the server for deletion after its processes have terminated and any epilogue or execjob_epilogue hook has run.

When this method is used in a non-execution hook script, it raises a Python "NotImplementedError" exception.

If the job.delete() method is used in an execjob_end hook, it has no effect, because in this case the server has already performed end-of-job processing before the execution hook runs.

The job.delete() method overrides the job.rerun() method. If both are used, job.delete() takes precedence.

6.6.2.4 Job Object Method to Release Vnodes

job.release_nodes()

job.release_nodes(keep_select=<select specification>)

Automatically selects vnodes that satisfy the new request and are healthy, keeps them in the job's vnode request, and releases all others. The method automatically trims out any vnodes in the pbs.event().vnode_list_fail[] list.

You can call pbs.event().job.release_nodes(keep_select = <desired vnodes>) in an execjob_launch or execjob_prologue hook. Note that despite the method being named "release_nodes", it **keeps** the specified vnodes and **releases** all other vnodes. You can specify the job's original vnode request as the vnodes to keep.

The pbs.event().job.release_nodes() method returns a PBS job object which has the updated values for the job's exec_vnode and Resource_List attributes.

This method is only effective when it runs at the primary MoM.

This method can be used only when it's used for a job whose tolerate_node_failures attribute is set to *job_start* or *all*.

6.6.2.4.i Advice and Recommendations for Using release_nodes Method

- Put the call to this method in an `'if pbs.event().job.in_ms_mom()'` clause
- Request vnodes that are a subset of the existing vnode request
- Because an execjob_launch hook is also called when spawning tasks via `pbsdsh` and `tm_spawn`, ensure that any execjob_launch hook invoking release_nodes() has 'PBS_NODEFILE' in the pbs.event().env list. The presence of 'PBS_NODEFILE' in the environment ensures that the primary MoM is executing on behalf of starting the top level job, and not spawning a sister task. You can add the following at the top of the hook:

```
if 'PBS_NODEFILE' not in pbs.event().env:
   pbs.event().accept()
...
pbs.release_nodes(keep_select=...)
```

- On Windows, where PBS_NODEFILE always appears in pbs.event().env, put the following at the top of any execjob_launch hook:

```
if any("mom_open_demux.exe") in s for s in e.argv):
   e.accept()
```

6.6.2.4.ii Side Effects of Using release_nodes() Method

When release_nodes() is successfully executed from execjob_prologue or execjob_launch hooks, the following happen:

- PBS generates the *s* accounting record.
- The primary MoM notifies the sister MoMs to update their internal nodes tables, so that the task manager API (e.g. `tm_spawn`, `pbsdsh`) will be aware of the change in the future.
- If the pbs_cgroups hook is enabled, the cgroup already created for the job is updated to match the job's new resources. If the kernel rejects the update to the job's cgroup resources, the job is aborted at the execution host, and requeued/rerun at the server.

6.6.2.5 Job Object Method to Re-run Job

job.rerun()

When this method is used in an execution hook, the job is flagged at the server for requeueing after its processes have terminated and any epilogue or execjob_epilogue hook has run.

When this method is used in a non-execution hook script, it raises a Python "NotImplementedError" exception.

If the job.rerun() method is used in an execjob_end hook, it has no effect, because in this case the server has already performed end-of-job processing before the execution hook runs.

The job.delete() method overrides the job.rerun() method. If both are used, job.delete() takes precedence.

6.7 The exec_vnode Object

pbs.exec_vnode

An exec_vnode object represents a job's exec_vnode attribute.

6.7.1 The exec_vnode Object Members

A pbs.exec_vnode object has the following member:

6.7.1.1 The exec_vnode Chunks Member

pbs.exec_vnode.chunks[]

List of pbs.vchunk objects. These objects represent the chunks assigned to a job. See section 6.8, "Chunk Objects", on page 143.

6.7.2 Using pbs.vchunk Objects in exec_vnode

- To get a list of pbs.vchunks in pbs.event().job.exec_vnode:

  pbs.event().job.exec_vnode.chunks

  For example, to log the name of the vnode containing each vchunk:

```
chunklist = pbs.event().job.exec_vnode.chunks
for chunk in chunklist:
    pbs.logmsg(pbs.LOG_DEBUG, "chunk.vnode_name=%s " % (chunk.vnode_name))
```

- To get a pbs.vchunk with a specific index:

  pbs.event().job.exec_vnode.chunks[<index>]

- For example, to get the vchunk in pbs.event().job.exec_vnode with index number *2*:

  pbs.event().job.exec_vnode.chunks[2]

Example 6-20: List the job ID, vnode name, and resources in exec_vnode:

```
j = pbs.event().job
pbs.logmsg(pbs.LOG_DEBUG, "job %s exec_vnode = %s" % (j.id, j.exec_vnode))

chunklist = j.exec_vnode.chunks
for c in chunklist:
    pbs.logmsg(pbs.LOG_DEBUG, "c.vnode_name=%s " % (c.vnode_name))

    for r in c.chunk_resources.keys():
        pbs.logmsg(pbs.LOG_DEBUG, "c.chunk_resources[%s]=%s" % (r,
            c.chunk_resources[r]))
```

Sample output:

```
10:16:53;0006;Server@jobim;Hook;Server@jobim;job 153.jobim exec_vnode  =
    (jobim[2]:ncpus=2:mem=10240kb)+ (jobim[1]:ncpus=2:mem=10240kb) +
    (jobim[3]:ncpus=2:mem=2048kb)
10:16:53;0006;Server@jobim;Hook;Server@jobim;c.vnode_name= jobim[2]
    10:16:53;0006;Server@jobim;Hook;Server@jobim; c.chunk_resources[ncpus]=2
10:16:53;0006;Server@jobim;Hook;Server@jobim; c.chunk_resources[mem]=10240kb
10:16:53;0006;Server@jobim;Hook;Server@jobim; c.vnode_name=jobim[1]
10:16:53;0006;Server@jobim;Hook;Server@jobim; c.chunk_resources[ncpus]=2
10:16:53;0006;Server@jobim;Hook;Server@jobim; c.chunk_resources[mem]=10240kb
10:16:53;0006;Server@jobim;Hook;Server@jobim; c.vnode_name=jobim[3]
10:16:53;0006;Server@jobim;Hook;Server@jobim; c.chunk_resources[ncpus]=2
    10:16:53;0006;Server@jobim;Hook;Server@jobim; c.chunk_resources[mem]=2048kb
```

6.7.3 Restrictions on exec_vnode Objects

A job's exec_vnode attribute is read-only. You cannot set its value, and you cannot build an exec_vnode object using pbs.vchunk objects.

6.8 Chunk Objects

pbs.vchunk

A pbs.vchunk object represents a chunk specification. It is used in a job's exec_vnode attribute or select statement.

6.8.1 Chunk Object Members and Methods

A pbs.vchunk object has the following members:

6.8.1.1 Chunk Object Vnode Name Member

vchunk.vnode_name

Name of the vnode from which the chunk is taken.

Python type: *str*

6.8.1.2 Chunk Object Chunk Resources Member

vchunk.chunk_resources[]

Resources assigned to the chunk.

Python type: Dictionary containing *<resource name>=<value>* pairs.

Syntax: *chunk_resources['<resource name>'] = <resource value>* where *<resource name>* is any custom or built-in resource.

6.8.1.3 Chunk Object Method to Return chunk_resources Keys

vchunk.chunk_resources.keys()

Returns list of <*resource name*> keys of chunk_resources[]. This list makes it convenient to list all the values of chunk_resources[].

6.9 Reservation Objects

pbs.resv

A pbs.resv object represents a PBS reservation. If the reservation is associated with the triggering event, you can read and set reservation attributes and resources in a resvsub hook, and read them in a resv_end hook.

We list the reservation attributes and resources that can be set in reservation hooks in Table 5-10, “Reservation Attributes Readable & Settable in Reservation Hooks,” on page 63.

If the reservation is retrieved through the server, and is not associated with the triggering event, you can read all its attributes and resources, but set none.

If you are working with the reservation being created using `pbs_rsub`, you must use *pbs.event().resv*. The server cannot return information about the reservation, because it has not yet been created.

In order to retrieve information about the reservation associated with the triggering action, you must use a reference to the reservation object represented by:

pbs.event().resv

To get a copy of a particular reservation, use:

pbs.server().resv("<reservation name>")

To get a list of the reservations at a server:

pbs.server().resvs()

6.9.1 Reservation Object Members

A pbs.resv object has members that represent reservation attributes, and the resvid member which exists for the job object but is not an attribute of a reservation.

6.9.1.1 Reservation ID Member

resv.resvid

The reservation ID.

Example: "`R221.myhost`".

This member is read-only.

Python type: *str*

6.9.1.2 Reservation Attribute Members

resv.<attribute name>

The reservation attribute named *<attribute name>*. Each member is spelled exactly like the corresponding attribute.

6.9.1.3 Setting Reservation Object Attribute Values

You can set, but not unset, reservation object attributes.

To see a list of which reservation attributes can be read and set by each hook, see Table 5-10, "Reservation Attributes Readable & Settable in Reservation Hooks," on page 63.

Some attributes require creation methods when setting them. See section 5.2.4.3, "Determining Whether to Use Creation Method to Set Attribute or Resource", on page 46. To set a simple reservation object attribute:

```
pbs.resv.<attribute name> = <attribute value>
```

Reservation attribute creation methods are listed in section 6.15.3, "PBS Types and Their Methods", on page 168.

See section 5.2.4, "Using Attributes and Resources in Hooks", on page 45.

6.9.1.4 Examples of Using Reservation Object Attributes

Example 6-21: Get the reservation's owner:

```
owner = pbs.server().resv(<reservation ID>).Reserve_Owner
```

Example 6-22: Reset the reservation's name:

```
pbs.event().resv(<reservation ID>).Reserve_Name = "Resv2008"
```

6.9.2 Using Reservation States

6.9.2.1 Reservation State Constant Objects

The pbs.resv.reserve_state member represents the state of the reservation. It can take on the following values, which are represented by constant objects:

Table 6-33: Reservation State Objects

Object	State
pbs.RESV_STATE_NONE	*RESV_NONE*
pbs.RESV_STATE_UNCONFIRMED	*RESV_UNCONFIRMED*
pbs.RESV_STATE_CONFIRMED	*RESV_CONFIRMED*
pbs.RESV_STATE_WAIT	*RESV_WAIT*
pbs.RESV_STATE_TIME_TO_RUN	*RESV_TIME_TO_RUN*
pbs.RESV_STATE_RUNNING	*RESV_RUNNING*
pbs.RESV_STATE_FINISHED	*RESV_FINISHED*
pbs.RESV_STATE_BEING_DELETED	*RESV_BEING_DELETED*
pbs.RESV_STATE_DELETED	*RESV_DELETED*
pbs.RESV_STATE_DELETING_JOBS	*RESV_DELETING_JOBS*
pbs.RESV_STATE_DEGRADED	*RESV_DEGRADED*
pbs.RESV_STATE_BEING_ALTERED	*RESV_BEING_ALTERED*
pbs.RESV_STATE_IN_CONFLICT	*RESV_IN_CONFLICT*

6.9.2.2 Getting Human-readable Names for Reservation State Values

The pbs.REVERSE_RESV_STATE object is a Python dictionary of reservation states mapped to human-readable names. This is useful for logging reservation information. The type for a state is found in pbs.resv.reserve_state.

6.9.2.2.i Syntax

<string> = pbs.REVERSE_RESV_STATE[<reservation state type>]

For example:

```
my_resv_state_str = pbs.REVERSE_RESV_STATE[my_resv.reserve_state]
```

or

<string> = pbs.REVERSE_RESV_STATE[pbs.<reservation state>]

For example:

```
my_resv_state_str = pbs.REVERSE_RESV_STATE[pbs.RESV_STATE_CONFIRMED]
```

6.9.2.2.ii Example

Example 6-23: Printing a human-readable name for a pbs.RESV_STATE_CONFIRMED reservation state using the type:

If the reservation is my_resv and the state is pbs.RESV_STATE_CONFIRMED:

```
print(pbs.REVERSE_RESV_STATE[my_resv.reserve_state])
```

results in:

```
RESV_STATE_CONFIRMED
```

6.10 Vnode Objects

pbs.vnode

A pbs.vnode object represents a PBS vnode.

The way in which you retrieve a vnode controls what you can do with the vnode.

If a vnode is retrieved through an event, using *pbs.event().v node_list[]*, and is managed by the same MoM where the event hook runs:

- You can set the vnode attributes listed in Table 5-8, “Vnode Attributes Readable & Settable via Job Events,” on page 61 and Table 5-9, “Vnode Attributes Readable & Settable via Reservation & Other Non-job Events,” on page 62.
- You can set the vnode resources listed in Table 5-13, “Vnode Resources Readable & Settable by Hooks via Job Events,” on page 66 and Table 5-14, “Vnode Resources Readable & Settable by Hooks via Reservation & Other Non-job Events,” on page 67.

However, if a vnode is not retrieved through an event, or is not managed by the same MoM where the hook runs, you can read all vnode attributes and resources, but set none.

The modifyvnode event has read-only access to a vnode before and after a state change. Execution events have access to the list of vnodes associated with the job. Periodic events have access to the list of vnodes managed by the local MoM. See section 6.3.2.24, “The Vnode List Event Member”, on page 123.

- To retrieve the list of vnodes associated with an execution event or a periodic event:

  pbs.event().vnode_list[]

- To retrieve a specific vnode that is associated with an execution or periodic event, use the list of vnodes associated with the event, and specify the vnode name:

pbs.event().vnode_list["<vnode name>"]

- To retrieve the vnodes associated with a pre-execution event, get the job's exec_vnode attribute:

  pbs.event().job.exec_vnode

- To retrieve the server's list of vnodes:

  pbs.server().vnodes()

- To retrieve a named vnode through the server:

  pbs.server().vnode("<vnode name>")

6.10.1 Vnode Object Members

vnode.<attribute name>

A pbs.vnode object has a member representing each attribute, and each member is spelled exactly like the corresponding attribute.

We list which vnode attributes can be set by each hook in Table 5-8, “Vnode Attributes Readable & Settable via Job Events,” on page 61 and Table 5-9, “Vnode Attributes Readable & Settable via Reservation & Other Non-job Events,” on page 62.

See section 5.2.4.3, “Determining Whether to Use Creation Method to Set Attribute or Resource”, on page 46. Attribute creation methods are listed in section 6.15.3, “PBS Types and Their Methods”, on page 168. See section 5.2.4, “Using Attributes and Resources in Hooks”, on page 45.

6.10.1.1 The topology_info Attribute Member

vnode.topology_info

Vnode attribute. The topology_info vnode attribute shows topology information. This attribute is visible only in hooks, and can be used only in hooks.

Python type: *str*

6.10.1.2 Vnode Attribute Restrictions

- The only vnode attribute that can be changed by a pre-execution hook is the state attribute
- The only pre-execution hook that can change the vnode state attribute is the runjob hook
- Execution and periodic hooks can change all settable vnode attributes

6.10.2 Vnode Object Methods

6.10.2.1 Vnode Object Members to Retrieve Vnode States

vnode.extract_state_ints()

Returns a list of the integer values currently set in the vnode's state bits.

vnode.extract_state_strs()

Returns a list of the string values currently set in the vnode's state bits.

6.10.3 Vnode Type Constant Objects

The pbs.vnode.ntype member represents the type of the vnode. It can take on the following values:

Table 6-34: Vnode Type Objects

Object	Type
pbs.ND_PBS	Represents *pbs* value for vnode ntype attribute

6.10.4 Vnode Sharing Constant Objects

The pbs.vnode.sharing member represents the vnode's sharing attribute. It can take on the following values:

Table 6-35: Vnode Sharing Objects

Object	Sharing Value
pbs.ND_DEFAULT_EXCL	Represents *default_excl* vnode sharing attribute value
pbs.ND_DEFAULT_EXCLHOST	Represents *default_exclhost* vnode sharing attribute value
pbs.ND_DEFAULT_SHARED	Represents *default_shared* vnode sharing attribute value
pbs.ND_FORCE_EXCL	Represents *force_excl* vnode sharing attribute value
pbs.ND_FORCE_EXCLHOST	Represents *force_exclhost* vnode sharing attribute value
pbs.ND_IGNORE_EXCL	Represents *ignore_excl* vnode sharing attribute value

6.10.5 Using Vnode States

6.10.5.1 Vnode State Constant Objects

The pbs.vnode.state member represents the state of the vnode. It can take on the following values:

Table 6-36: Vnode State Constant Objects

Object	State
pbs.ND_STATE_FREE	Represents *free* vnode state Replaces pbs.ND_FREE
pbs.ND_STATE_OFFLINE	Represents *offline* vnode state Replaces pbs.ND_OFFLINE
pbs.ND_STATE_DOWN	Represents *down* vnode state Replaces pbs.ND_DOWN
pbs.ND_STATE_UNRESOLVABLE	Represents *unresolvable* vnode state Replaces pbs.ND_UNRESOLVABLE
pbs.ND_STATE_JOBBUSY	Represents *job-busy* vnode state Replaces pbs.ND_JOBBUSY

Table 6-36: Vnode State Constant Objects

Object	State
pbs.ND_STATE_STALE	Represents *stale* vnode state Replaces pbs.ND_STALE
pbs.ND_STATE_JOB_EXCLUSIVE	Represents *job-exclusive* vnode state Replaces pbs.ND_JOB_EXCLUSIVE
pbs.ND_STATE_BUSY	Represents *busy* vnode state Replaces pbs.ND_BUSY
pbs.ND_STATE_UNKNOWN	Represents *state-unknown, down* vnode state
pbs.ND_STATE_PROV	Represents *provisioning* vnode state Replaces pbs.ND_PROV
pbs.ND_STATE_WAIT_PROV	Represents *wait-provisioning* vnode state Replaces pbs.ND_WAIT_PROV
pbs.ND_STATE_RESV_EXCLUSIVE	Represents resv-exclusive vnode state Replaces pbs.ND_RESV_EXCLUSIVE
pbs.ND_STATE_MAINTENANCE	Represents *maintenance* vnode state
pbs.ND_STATE_SLEEP	Represents *sleep* vnode state

6.10.5.2 Getting Human-readable Names for Vnode State

The pbs.REVERSE_NODE_STATE object is a Python dictionary of vnode states mapped to human-readable names. This is useful for logging vnode information. The type for a vnode state is found in pbs.vnode.state.

6.10.5.2.i Syntax

<string> = pbs.REVERSE_NODE_STATE[<vnode state type>]

For example:

```
my_vnode_state_str = pbs.REVERSE_NODE_STATE[my_vnode.state]
```

or

<string> = pbs.REVERSE_NODE_STATE[pbs.<vnode state>]

For example:

```
my_vnode_state_str = pbs.REVERSE_NODE_STATE[pbs.ND_STATE_FREE]
```

6.10.5.2.ii Example

Example 6-24: Printing a human-readable name for a pbs.ND_STATE_FREE vnode state using the type:

If the vnode is my_vnode and the state is pbs.ND_STATE_FREE:

```
print(pbs.REVERSE_NODE_STATE[my_vnode.state])
```

results in:

```
ND_STATE_FREE
```

6.11 Management Objects

pbs.management

A pbs.management object represents a management operation in which a qmgr command is used to operate on an entity such as a server, scheduler, queue, vnode, resource, hook, or built-in hook. For a list of entities see section 6.11.2.3, "Management Member: Entity Name", on page 153.

To refer to a management object in a hook and name it "mgt":

mgt = pbs.event().management

Example 6-25: Using `qmgr` to create a vnode via `qmgr -c 'create node mom1'`:

- The entity name is captured in the objname management member; here it is "mom1"
- The entity type is captured in the objtype management member; in this case it is *pbs.MGR_OBJ_NODE*
- The management object command is captured in the cmd management member; it is *pbs.MGR_CMD_CREATE*

Each operation on an entity can include one or more targets and alteration. Each target and associated alteration is captured in a pbs.server_attribute object; these objects are found in the attribs[] management operation member. See section 6.11.2.1, "Management Member: List of Targets and Alterations", on page 151.

Example 6-26: We have a management object generated by using `qmgr` to set multiple attributes via `qmgr -c 'set node mom1 state=free,resources_available.ncpus=1024,mem-=16777216'`:

- The entity name is "mom1"
- The entity type is *pbs.MGR_OBJ_NODE*
- The management object command is *pbs.MGR_CMD_SET*
- The management operation includes three targets and associated alterations:
  1. Target is the vnode state, and the alteration is setting the state to *Free*
  2. Target is resources_available.ncpus, and the alteration is setting it to *1024*
  3. Target is resources_available.mem, and the alteration is reducing it by *16777216*

The reply fields in the management object are populated based on the success or failure of the requested operation.

We show a detailed example of a management object in Example Management Object.

6.11.1 Example Management Object

Example 6-27: We use the following command:

```
qmgr -c "set node mom1
    state=free,resources_available.ncpus=1024,resources_available.mem-=16777216"
```

Our management event hook script contains:

```
mgt = pbs.event().management
```

So the command above results in the following values in the mgt management object:

`mgt.cmd` <-- *pbs.MGR_CMD_SET*

`mgt.objtype` <-- *pbs.MGR_OBJ_NODE*

`mgt.objname` <-- "*mom1*"

`mgt.request_time` <-- (Timestamp in seconds since epoch)

In addition, the mgt object has a list of pbs.server_attribute instances, called "mgt.attribs". These represent the alterations we gave to the `qmgr` command, as well as any alterations performed while processing the request.

In our example, the mgt.attribs list consists of three elements, each representing an alteration. We show the effect on mgt.attribs[] of each alteration:

Reducing resources_available.mem by *16777216*:

mgt.attribs[0].name <-- "*resources_available*"
mgt.attribs[0].resource <-- "*mem*"
mgt.attribs[0].op <-- *pbs.BATCH_OP_DECR*
mgt.attribs[0].value <-- "*16777216*"
mgt.attribs[0].flags <-- *0*
mgt.attribs[0].sisters <-- *[]*

Setting the vnode's resources_available.ncpus to *1024*:

mgt.attribs[1].name <-- "*resources_available*"
mgt.attribs[1].resource <-- "*ncpus*"
mgt.attribs[1].op <-- *pbs.BATCH_OP_SET*
mgt.attribs[1].value <-- "*1024*"
mgt.attribs[1].flags <-- *0*
mgt.attribs[1].sisters <-- *[]*

Setting the vnode state to *Free*:

mgt.attribs[2].name <-- "*state*"
mgt.attribs[2].resource <-- (No resource)
mgt.attribs[2].op <-- *pbs.BATCH_OP_SET*
mgt.attribs[2].value <-- "*free*"
mgt.attribs[2].flags <-- *0*
mgt.attribs[2].sisters <-- *[]*

If the operation succeeds, the reply choice has a valid reply_code, and we expect values like the following:

mgt.reply_choice <-- *pbs.BRP_CHOICE_NULL*
mgt.reply_code <-- *0*
mgt.reply_auxcode <-- *0*
mgt.reply_text <-- (No text)

If the operation fails because the node does not exist, the reply choice has values like the following:

mgt.reply_choice <-- *pbs.BRP_CHOICE_Text*
mgt.reply_code <-- *15062*
mgt.reply_auxcode <-- *0*
mgt.reply_text <-- *"Unknown node "*

6.11.2 Management Object Members

6.11.2.1 Management Member: List of Targets and Alterations

management.attribs[]

List of pbs.server_attribute objects. Each pbs.server_attribute object represents one target and associated alteration in a management operation.

Note that a pbs.server_attribute object is not the same as a pbs.server().<attribute name> object.

To reference a specific target-alteration member in the list:

pbs.event().management.attribs[<index>]

For example:

```
pbs.event().management.attribs[0]
```

Example 6-28: Our qmgr command is `qmgr -c 'set node Node1 resources_available.ncpus=4'`:

The target is resources_available.ncpus and the alteration is setting it to *4*. If the hook script calls the management object "mgt", the mgt.attribs[0] member looks like this:

`mgt.attribs[0].name` <-- "*resources_available*"

`mgt.attribs[0].resource` <-- "*ncpus*"

`mgt.attribs[0].op` <-- *pbs.BATCH_OP_SET*

`mgt.attribs[0].value` <-- "*4*"

`mgt.attribs[0].flags` <-- *0*

`mgt.attribs[0].sisters` <-- *[]*

See section 6.12, “server_attribute Objects”, on page 156.

6.11.2.2 Management Member: Command

management.cmd

The management command, such as "create" or "set", used in a qmgr directive to operate on an entity such as a queue or vnode.

To reference the command in a management object:

pbs.event().management.cmd

Commands used in qmgr directives:

Table 6-37: Commands Used in Directives

Management Command	Command Name	qmgr Command	Abbr	Effect
pbs.MGR_CMD_NONE	MGR_CMD_NONE	(none)	---	None
pbs.MGR_CMD_CREATE	MGR_CMD_CREATE	create	c	Creates object
pbs.MGR_CMD_DELETE	MGR_CMD_DELETE	delete	d	Deletes object
pbs.MGR_CMD_SET	MGR_CMD_SET	set	s	Sets value of attribute
pbs.MGR_CMD_UNSET	MGR_CMD_UNSET	unset	u	Unsets value of attribute
pbs.MGR_CMD_LIST	MGR_CMD_LIST	list	l	Lists object attributes and their values
pbs.MGR_CMD_PRINT	MGR_CMD_PRINT	print	p	Prints creation and configuration commands
pbs.MGR_CMD_ACTIVE	MGR_CMD_ACTIVE	active	a	Specifies active objects
pbs.MGR_CMD_IMPORT	MGR_CMD_IMPORT	import	i	Imports hook or configuration file
pbs.MGR_CMD_EXPORT	MGR_CMD_EXPORT	export	e	Exports hook or hook configuration file
pbs.MGR_CMD_LAST	MGR_CMD_LAST	---	---	---

Table 6-37: Commands Used in Directives

Management Command	Command Name	qmgr Command	Abbr	Effect
---	---	`exit`		Exits (quits) the `qmgr` session
---	---	`help or ?`	`h, ?`	Prints usage to `stdout`
---	---	`quit`	`q`	Quits (exits) the `qmgr` session

6.11.2.2.i Getting Human-readable Names for Commands

The pbs.REVERSE_MGR_CMDS object is a Python dictionary of management commands mapped to human-readable names. This is useful for logging management information. The type for a management command is found in management.cmd.

Syntax

<string> = pbs.REVERSE_MGR_CMDS[<management command type>]

For example:

```
my_mgt_cmd_str = pbs.REVERSE_MGR_CMDS[my_mgt_operation.cmd]
```

or

<string> = pbs.REVERSE_MGR_CMDS[pbs.<management operation command>]

For example:

```
my_mgt_cmd_str = pbs.REVERSE_MGR_CMDS[pbs.MGR_CMDS_SET]
```

Example

Example 6-29: Printing a human-readable name for a pbs.MGR_CMDS_SET management command using the type:

If the management operation is `my_mgt_operation` and the command is pbs.MGR_CMDS_SET:

```
print(pbs.REVERSE_MGR_CMDS[my_mgt_operation.cmd])
```

results in:

```
MGR_CMDS_SET
```

6.11.2.3 Management Member: Entity Name

management.objname

Name of the entity being operated on in the `qmgr` command. For example, if the management operation is setting the state of the vnode named "Node1", objname is *Node1*.

To reference the name in a management object:

pbs.event().management.objname

6.11.2.4 Management Member: Entity Type

management.objtype

Type of the entity being operated on. For example, if the management operation is setting a vnode's resource value, the type is pbs.MGR_OBJ_NODE.

To reference the entity type in a management object:

pbs.event().management.objtype

Object types in management objects:

Table 6-38: Management Object Types

Object Type	Type Name	Object Name	Abbr.	Object
pbs.MGR_OBJ_SERVER	MGR_OBJ_SERVER	*server*	*s*	server
pbs.MGR_OBJ_QUEUE	MGR_OBJ_QUEUE	*queue*	*q*	queue
pbs.MGR_OBJ_NODE	MGR_OBJ_NODE	*node*	*n*	vnode
pbs.MGR_OBJ_RSC	MGR_OBJ_RSC	*resource*	*r*	resource
pbs.MGR_OBJ_SCHED	MGR_OBJ_SCHED	*sched*	*sc*	default scheduler
				multisched
pbs.MGR_OBJ_HOOK	MGR_OBJ_HOOK	*hook*	*h*	hook
pbs.MGR_OBJ_PBS_HOOK	MGR_OBJ_PBS_HOOK	*pbshook*	*p*	built-in hook

6.11.2.4.i Getting Human-readable Names for Object Types

The pbs.REVERSE_MGR_OBJS object is a Python dictionary of management object types mapped to human-readable names. This is useful for logging management information. The type for a management object type is found in pbs.management.cmd.

6.11.2.4.ii Syntax

<string> = pbs.REVERSE_MGR_OBJS[<management object type>]

For example:

```
my_obj_type_str = pbs.REVERSE_MGR_OBJS[my_mgt_operation.objtype]
```

or

<string> = pbs.REVERSE_MGR_OBJS[pbs.<management operation object type>]

For example:

```
my_obj_type_str = pbs.REVERSE_MGR_OBJS[pbs.MGR_OBJS_QUEUE]
```

6.11.2.4.iii Example of Getting Human-readable Name for Object Type

Example 6-30: Printing a human-readable name for a pbs.MGR_OBJS_HOOK management object type using the type:

If the management operation is `my_mgt_operation` and the object type is pbs.MGR_OBJS_HOOK:

```
print(pbs.REVERSE_MGR_OBJS[my_mgt_operation.objtype])
```

results in:

```
MGR_OBJS_HOOK
```

6.11.2.5 Management Member: Reply Auxiliary Error Code

management.reply_auxcode

Auxiliary error code.

To reference the auxiliary code in a management object:

pbs.event().management.reply_auxcode

6.11.2.6 Management Member: Reply Choice

management.reply_choice

Type of reply being returned to the user via the server management operation.

Table 6-39: Reply Choice Types

Reply Type	Reply Name
pbs.BRP_CHOICE_NULL	BRP_CHOICE_NULL
pbs.BRP_CHOICE_Queue	BRP_CHOICE_Queue
pbs.BRP_CHOICE_RdytoCom	BRP_CHOICE_RdytoCom
pbs.BRP_CHOICE_Commit	BRP_CHOICE_Commit
pbs.BRP_CHOICE_Select	BRP_CHOICE_Select
pbs.BRP_CHOICE_Status	BRP_CHOICE_Status
pbs.BRP_CHOICE_Text	BRP_CHOICE_Text
pbs.BRP_CHOICE_Locate	BRP_CHOICE_Locate
pbs.BRP_CHOICE_RescQuery	BRP_CHOICE_RescQuery
pbs.BRP_CHOICE_PreemptJobs	BRP_CHOICE_PreemptJobs

6.11.2.6.i Getting Human-readable Names for Reply Choice Types

The pbs.REVERSE_BRP_CHOICES object is a Python dictionary of management reply choice types mapped to human-readable names. This is useful for logging management information. The type for a management reply choice type is found in pbs.management.reply_choice.

Syntax

<string> = pbs.REVERSE_BRP_CHOICES[<management reply choice type>]

For example:

```
my_reply_choice_str = pbs.REVERSE_BRP_CHOICES[my_mgt_operation.reply_choice]
```

or

<string> = pbs.REVERSE_BRP_CHOICES[pbs.<management operation reply choice type>]

For example:

```
my_reply_choice_str = pbs.REVERSE_BRP_CHOICES[pbs.BRP_CHOICE_Status]
```

Example

Example 6-31: Printing a human-readable name for a pbs.BRP_CHOICE_Status management reply choice type using the type:

If the management operation is my_mgt_operation and the reply choice type is pbs.BRP_CHOICE_Status:

```
print(pbs.REVERSE_BRP_CHOICES[my_mgt_operation.reply_choice])
```

results in:

```
BRP_CHOICE_Status
```

6.11.2.7 Management Member: Reply Code

management.reply_code

Code returned to the user via the management operation.

To reference the reply code in a management object:

pbs.event().management.reply_code

6.11.2.8 Management Member: Reply Text

management.reply_text

Text returned to the user via the management operation.

To reference the text in a management object:

pbs.event().management.reply_text

6.11.2.9 Management Member: Request Time

management.request_time

Timestamp of request; time of the request in seconds since epoch.

To reference the request time in a management object:

pbs.event().management.request_time

6.12 server_attribute Objects

pbs.server_attribute

Represents a target and its associated alteration in a `qmgr` operation. The target is an attribute of an entity such as a server or vnode, and associated alteration is the change to be performed on the attribute. For example, if we set a vnode's resources_available.ngpus to 2, while the management object type and name represent a vnode, the server_attribute represents a target that is "resources_available.ngpus" and the associated alteration is setting it to "2".

To reference a server_attribute object:

pbs.event().management.attribs[<index>]

For example:

```
pbs.event().management.attribs[0]
```

Each management object has a list of zero or more server_attribute objects representing the alterations to be made to target objects; the list is called "attribs[]".

Example 6-32: Our management object is called "mgt". We use the command `qmgr -c 'set node Node1 resources_available.ngpus=2'`.

The target is resources_available.ngpus.

The alteration is setting it to 2.

The server_attribute object looks like this:

```
mgt.attribs[0].name <-- "resources_available"
mgt.attribs[0].resource <-- "ngpus"
mgt.attribs[0].op <-- pbs.BATCH_OP_SET
mgt.attribs[0].value <-- "2"
mgt.attribs[0].flags <-- 0
mgt.attribs[0].sisters <-- []
```

Note that a pbs.server_attribute object is not the same as a pbs.server().<attribute name> object.

6.12.1 server_attribute Object Members

Each pbs.server_attribute object has its own Python attributes, such as name and value. For convenience, we are calling these Python attributes *members* of the server_attribute object.

To reference a server_attribute object member:

pbs.event().management.attribs[<index>].<attribute>

For example:

```
pbs.event().management.attribs[0].name
```

6.12.1.1 server_attribute Object Member: Name

server_attribute.name

Name of the server_attribute object. For example, if the qmgr operation is setting the state of vnode Node1 to *Free*, the name member of the server_attribute object is "*state*". And if the qmgr operation is setting the value of resources_available.ncpus to *2*, the name member is "resources_available".

To reference a server_attribute name member:

pbs.event().management.attribs[<index>].name

6.12.1.2 server_attribute Object Member: Resource

server_attribute.resource

If the server_attribute object is a resource, its resource member is set to the resource being altered. For example, if the command is `qmgr -c 'set node Node1 resources_available.ncpus=4'`, the resource member is "ncpus".

To reference a server_attribute resource member:

pbs.event().management.attribs[<index>].resource

6.12.1.3 server_attribute Object Member: Value

server_attribute.value

Value of the attribute. For example, if the qmgr operation is setting the state of vnode Node1 to *Free*, the value of the server_attribute object is "*free*".

To reference a server_attribute value member:

pbs.event().management.attribs[<index>].value

6.12.1.4 server_attribute Object Member: Operator

server_attribute.op

Operation to be performed on the server_attribute target object.

To reference a server_attribute op member:

pbs.event().management.attribs[<index>].op

Attribute operators:

Table 6-40: Attribute Operators

Operation Type	Operation Name	Symbol	Effect
pbs.BATCH_OP_SET	BATCH_OP_SET	=	Sets the value of the attribute
pbs.BATCH_OP_UNSET	BATCH_OP_UNSET		Unsets the value of the attribute
pbs.BATCH_OP_INCR	BATCH_OP_INCR	+=	Increases the value of the attribute
pbs.BATCH_OP_DECR	BATCH_OP_DECR	-=	Decreases the value of the attribute
pbs.BATCH_OP_EQ	BATCH_OP_EQ		Tests for equality
pbs.BATCH_OP_NE	BATCH_OP_NE		Tests for inequality
pbs.BATCH_OP_GE	BATCH_OP_GE		Tests for being greater than or equal
pbs.BATCH_OP_GT	BATCH_OP_GT		Tests for being greater than
pbs.BATCH_OP_LE	BATCH_OP_LE		Tests for being less than or equal
pbs.BATCH_OP_LT	BATCH_OP_LT		Tests for being less than

6.12.1.4.i Getting Human-readable Names for Operators

The pbs.REVERSE_BATCH_OPS object is a Python dictionary of management operators mapped to human-readable names. This is useful for logging management information. The type for a management operator is found in pbs.management.server_attribute.op.

Syntax

<string> = pbs.REVERSE_BATCH_OPS[<management operator type>]

For example:

```
my_operator_str = pbs.REVERSE_BATCH_OPS[my_svr_attrib.op]
```

or

<string> = pbs.REVERSE_BATCH_OPS[pbs.<management operator>]

For example:

```
my_operator_str = pbs.REVERSE_BATCH_OPS[pbs.BATCH_OP_SET]
```

Example

Example 6-33: Printing a human-readable name for a pbs.BATCH_OP_SET management object type using the type:

If the server_attribute is `my_svr_attrib` and the operator is pbs.BATCH_OP_SET:

```
print(pbs.REVERSE_BATCH_OPS[my_svr_attrib.op])
```

results in:

```
BATCH_OP_SET
```

6.12.1.5 server_attribute Object Member: Flags

server_attribute.flags

Attribute flags associated with the server_attribute object.

To reference a server_attribute flags member:

pbs.event().management.attribs[<index>].flags

Attribute flags:

Table 6-41: Attribute Flags

Flag Type	Flag Name
pbs.ATR_VFLAG_SET	ATR_VFLAG_SET
pbs.ATR_VFLAG_MODIFY	ATR_VFLAG_MODIFY
pbs.ATR_VFLAG_DEFLT	ATR_VFLAG_DEFLT
pbs.ATR_VFLAG_MODCACHE	ATR_VFLAG_MODCACHE
pbs.ATR_VFLAG_INDIRECT	ATR_VFLAG_INDIRECT
pbs.ATR_VFLAG_TARGET	ATR_VFLAG_TARGET
pbs.ATR_VFLAG_HOOK	ATR_VFLAG_HOOK

6.12.1.5.i Getting Human-readable Names for Flags

The pbs.REVERSE_ATR_VFLAGS object is a Python dictionary of attribute flags mapped to human-readable names. This is useful for logging management information. The type for an attribute flag is found in pbs.management.server_attribute.flags.

Syntax

<string> = pbs.REVERSE_ATR_VFLAGS[<attribute flag type>]

For example:

```
my_flag_str = pbs.REVERSE_ATR_VFLAGS[my_svr_attrib.flags]
```

or

<string> = pbs.REVERSE_ATR_VFLAGS[pbs.<attribute flag>]

For example:

```
my_flag_str = pbs.REVERSE_ATR_VFLAGS[pbs.ATR_VFLAG_SET]
```

Example

Example 6-34: Printing a human-readable name for a pbs.ATR_VFLAG_SET attribute flag using the type:

If the server_attribute is `my_svr_attrib` and the flag is pbs.ATR_VFLAG_SET:

```
print(pbs.REVERSE_ATR_VFLAGS[my_svr_attrib.flags])
```

results in:

```
ATR_VFLAGS_SET
```

6.12.1.6 server_attribute Object Member: Co-resources

server_attribute.sisters

List of co-resources for the server_attribute object.

To reference a server_attribute sisters member:

pbs.event().management.attribs[<index>].sisters[<index>]

6.13 Configuration File Python Elements

6.13.1 Variable Containing Hook Configuration File Path

pbs.hook_config_filename

Contains the path to the hook's configuration file, or *None* if there is no configuration file.

6.13.2 Dictionary of PBS Configuration File Entries

pbs.pbs_conf[]

This is a dictionary of values which represent entries in the pbs.conf file.

This reflects the contents of /etc/pbs.conf on the host where a hook runs, so pre-execution event (server) hooks get the entries on the server host, and execution event (MoM) hooks get the entries on the execution host where the hook runs.

Example of using pbs.pbs.conf[]:

```
pbs.logmsg(pbs.LOG_DEBUG, "pbs home is %s" % (pbs.pbs_conf['PBS_HOME']))
```

If you change /etc/pbs.conf, HUP pbs_mom (Linux) and/or restart pbs_server to rebuild the dictionary with the new contents of pbs.conf.

Each parameter in the pbs.conf file is the key to its dictionary entry. The pbs.conf file can contain the following parameters:

Table 6-42: Parameters in pbs.conf

Parameter	Description
PBS_AUTH_METHOD	Specifies default authentication method and library to be used by PBS. Used only at authenticating client. Case-insensitive. Default value: *resvport* To use MUNGE, set to *munge*
PBS_BATCH_SERVICE_PORT	Port on which server listens. Default: 15001
PBS_BATCH_SERVICE_PORT_DIS	DIS port on which server listens.
PBS_COMM_LOG_EVENTS	Communication daemon log mask. Default: *511*
PBS_COMM_ROUTERS	Tells a pbs_comm the location of the other pbs_comms.
PBS_COMM_THREADS	Number of threads for communication daemon.
PBS_CORE_LIMIT	Limit on corefile size for PBS daemons. Can be set to an integer number of bytes or to the string "unlimited". If unset, core file size limit is inherited from the shell environment.
PBS_CP	Specifies command for MoM to use for local copy
PBS_DAEMON_SERVICE_USER	Username under which scheduler(s) run. Default: root
PBS_DATA_SERVICE_PORT	Used to specify non-default port for connecting to data service. Default: 15007

Table 6-42: Parameters in pbs.conf

Parameter	Description
PBS_ENCRYPT_METHOD	Specifies method and library for encrypting and decrypting data in client-server communication. Used only at authentication client side. Case-insensitive. To use TLS encryption in client-server communication, set this parameter to *tls*. No default; if this is not set, PBS does not encrypt or decrypt data.
PBS_ENVIRONMENT	Location of `pbs_environment` file.
PBS_EXEC	Location of PBS `bin` and `sbin` directories.
PBS_HOME	Location of PBS working directories.
PBS_LEAF_NAME	Tells endpoint what hostname to use for network. The value does not include a port, since that is usually set by the daemon. By default, the name of the endpoint's host is the hostname of the machine. You can set the name where an endpoint runs. This is useful when you have multiple networks configured, and you want PBS to use a particular network. The server only queries for the canonicalized address of the MoM host, unless you let it know via the Mom attribute; if you have set PBS_LEAF_NAME in `/etc/pbs.conf` to something else, make sure you set the Mom attribute at vnode creation. TPP internally resolves the name to a set of IP addresses, so you do not affect how `pbs_comm` works.
PBS_LEAF_ROUTERS	Location of endpoint's `pbs_comm` daemon(s).
PBS_LOCALLOG=<value>	Enables logging to local PBS log files. Valid values: 0: no local logging 1: local logging enabled Only available when using `syslog`.
PBS_LOG_HIGHRES_TIMESTAMP	Controls whether daemons on this host log timestamps in microseconds. Default timestamp log format is *HH:MM:SS*. With microsecond logging, format is *HH:MM:SS:XXXXXX*. Does not affect accounting log. Not applicable when using `syslog`. Overridden by environment variable of the same name. Valid values: *0*, *1*. Default: *0* (no microsecond logging)
PBS_MAIL_HOST_NAME	Used in addressing mail regarding jobs and reservations that is sent to users specified in a job or reservation's Mail_Users attribute. Optional. If specified, must be a fully qualified domain name. Cannot contain a colon (":"). For how this is used in email address, see section 2.2.3, "Specifying Mail Delivery Domain", on page 22.
PBS_MANAGER_SERVICE_PORT	Port on which MoM listens. Default: 15003
PBS_MOM_HOME	Location of MoM working directories.

Table 6-42: Parameters in pbs.conf

Parameter	Description
PBS_MOM_NODE_NAME	Name that MoM should use for parent vnode, and if they exist, child vnodes. If this is not set, MoM defaults to using the non-canonicalized hostname returned by `gethostname()`. If you use the IP address for a vnode name, set `PBS_MOM_NODE_NAME=<IP address>` in `pbs.conf` on the execution host. Dots are not allowed in this parameter unless they are part of an IP address.
PBS_MOM_SERVICE_PORT	Port on which MoM listens. Default: 15002
PBS_OUTPUT_HOST_NAME	Host to which all job standard output and standard error are delivered. If specified in `pbs.conf` on a job submission host, the value of PBS_OUTPUT_HOST_NAME is used in the host portion of the job's Output_Path and Error_Path attributes. If the job submitter does not specify paths for standard output and standard error, the current working directory for the `qsub` command is used, and the value of PBS_OUTPUT_HOST_NAME is appended after an at sign ("@"). If the job submitter specifies only a file path for standard output and standard error, the value of PBS_OUTPUT_HOST_NAME is appended after an at sign ("@"). If the job submitter specifies paths for standard output and standard error that include host names, the specified paths are used. Optional. If specified, must be a fully qualified domain name. Cannot contain a colon (":"). See "Delivering Output and Error Files" on page 60 in the PBS Professional Administrator's Guide.
PBS_PRIMARY	Hostname of primary server. Used only for failover configuration. Overrides PBS_SERVER_HOST_NAME. If you set PBS_LEAF_NAME on the primary server host, make sure that PBS_PRIMARY matches PBS_LEAF_NAME on the corresponding host. If you do not set PBS_LEAF_NAME on the server host, make sure that PBS_PRIMARY matches the hostname of the server host.
PBS_RCP	Location of `rcp` command if `rcp` is used.
PBS_REMOTE_VIEWER	Specifies remote viewer client. If not specified, PBS uses native Remote Desktop client for remote viewer. Set on submission host(s). Supported on Windows only.
PBS_SCHED_THREADS	Maximum number of scheduler threads. Scheduler automatically caps number of threads at the number of cores (or hyperthreads if applicable), regardless of value of this variable. Overridden by `pbs_sched -t` option and PBS_SCHED_THREADS environment variable. Default: 1

Table 6-42: Parameters in pbs.conf

Parameter	Description
PBS_SCP	Location of `scp` command if `scp` is used; setting this parameter causes PBS to first try `scp` rather than `rcp` for file transport.
PBS_SECONDARY	Hostname of secondary server. Used only for failover configuration. Overrides PBS_SERVER_HOST_NAME. If you set PBS_LEAF_NAME on the secondary server host, make sure that PBS_SECONDARY matches PBS_LEAF_NAME on the corresponding host. If you do not set PBS_LEAF_NAME on the server host, make sure that PBS_SECONDARY matches the hostname of the server host.
PBS_SERVER	Hostname of host running the server. Cannot be longer than 255 characters. If the short name of the server host resolves to the correct IP address, you can use the short name for the value of the PBS_SERVER entry in `pbs.conf`. If only the FQDN of the server host resolves to the correct IP address, you must use the FQDN for the value of PBS_SERVER. Overridden by PBS_SERVER_HOST_NAME and PBS_PRIMARY.
PBS_SERVER_HOST_NAME	The FQDN of the server host. Used by clients to contact server. Overridden by PBS_PRIMARY and PBS_SECONDARY failover parameters. Overrides PBS_SERVER parameter. Optional. If specified, must be a fully qualified domain name. Cannot contain a colon (":"). See "Contacting the Server" on page 60 in the PBS Professional Administrator's Guide.
PBS_START_COMM	Set this to *1* if a communication daemon is to run on this host.
PBS_START_MOM	Default is *0*. Set this to *1* if a MoM is to run on this host.
PBS_START_SCHED	**Deprecated**. Set this to *1* if default scheduler is to run on this host. Overridden by scheduler's scheduling attribute.
PBS_START_SERVER	Set this to *1* if server is to run on this host.
PBS_SUPPORTED_AUTH_METHODS	Specifies supported authentication methods for client-server communication. Used by authenticating server (PBS server, scheduler, MoM, or comm); ignored at client. Case-insensitive. If this parameter is set, PBS accepts only the methods listed. Format: comma-separated list of authentication methods. Default value: *resvport* Example: *munge,GSS*

Table 6-42: Parameters in pbs.conf

Parameter	Description
PBS_SYSLOG=<value>	Controls use of `syslog` facility under which the entries are logged. Valid values: 0: no syslogging 1: logged via LOG_DAEMON facility 2: logged via LOG_LOCAL0 facility 3: logged via LOG_LOCAL1 facility ... 9: logged via LOG_LOCAL7 facility
PBS_SYSLOGSEVR=<value>	Filters `syslog` messages by severity. Valid values: 0: only LOG_EMERG messages are logged 1: messages up to LOG_ALERT are logged ... 7: messages up to LOG_DEBUG are logged
PBS_TMPDIR	Location of temporary files/directories used by PBS components.

6.14 Constant Objects

Constant objects are used to represent PBS elements such as event types, job, server, reservation, and vnode states, log event classes, queue and vnode types, and exceptions. These objects cannot be modified. When the PBS module is imported, the constant objects are imported.

6.15 Object Members and Methods

The relationships between objects and methods are shown in Figure 6-1 and Figure 6-2.

Event object members are listed in Table 6-26, “Using Event Object Members in Job Events,” on page 116 and Table 6-27, “Using Event Object Members in Reservation and Other Non-job Events,” on page 117.

Non-event objects and object members are listed in Table 6-43, “PBS Objects and Object Members,” on page 165.

We list the methods available for each kind of event in Table 6-44, “Methods Available in Job Events,” on page 165 and Table 6-45, “Methods Available in Reservation and Other Non-job Events,” on page 167.

Each global method is described in section 6.15.3, “PBS Types and Their Methods”, on page 168.

Each event-only method is described in section 6.3.4, “Event-only Methods”, on page 125.

Each object-only method is described in the section for its object.

6.15.1 PBS Objects and Object Members

The following table lists PBS objects and their members, such as the server or jobs:

Table 6-43: PBS Objects and Object Members

Object	Object Member	Object Sub-member
pbs.hook_config_filename		
pbs.job	job.id	
	job.<attribute name>	
	pbs.exec_vnode (job attribute)	pbs.exec_vnode.chunks[]
	pbs.resv	
pbs.management	pbs.server_attribute	
pbs.pbs_conf[]		
pbs.queue	queue.<attribute name>	
	queue.name	
pbs.resv	resv.<attribute name>	
	resv.resvid	
pbs.server	pbs.server().<attribute name>	
	pbs.server().name	
pbs.vnode	vnode.<attribute name>	
	pbs.vchunk	vchunk.chunk_resources[]
		vchunk.vnode_name

6.15.2 Methods Available in Events

The following tables list all methods, and show which events can use each method. A "*y*" means that the hook can use the method, an "*n*" means it cannot, and an "*o*" means that it can but will have no effect:

Table 6-44: Methods Available in Job Events

Method	provision	queuejob	postqueuejob	movejob	modifyjob (before run)	runjob (on reject)	runjob (on accept)	jobobit	execjob_begin	execjob_prologue	execjob_launch	execjob_attach	execjob_postsuspend	execjob_preresume	execjob_preterm	execjob_epilogue	execjob_end
job.delete()	n	n	n	n	n	n	n	n	y	y	o	o	o	o	y	y	o
job.in_ms_mom()	n	y	y	y	y	y	y	y	y	y	o	o	y	y	y	y	y
job.is_checkpointed()	n	y	y	y	y	y	y	y	y	y	o	o	y	y	y	y	y
job.release_nodes()	n	n	n	n	n	n	n	n	n	y	y	n	n	n	n	n	n
job.rerun()	n	n	n	n	n	n	n	n	y	y	o	o	o	o	y	y	o
pbs.acl()	n	y	y	y	y	y	y	y	y	y	o	o	y	y	y	y	y

6.15.3 PBS Types and Their Methods

6.15.3.1 Method to Create or Set ACL

pbs.acl()

pbs.acl("[+|-]<entity>][,...]")

Creates an object representing a PBS ACL, from the specified formatted input string.

6.15.3.2 Method to Create or Set Command Argument List

pbs.args()

pbs.args("<args>")

where <*args*> are space-separated arguments to a command.

Creates an object representing the arguments to the command from the specified formatted input string <*args*>.

Example of setting a command argument list:

```
pbs.args("-Wsuppress_email=N -r y")
```

6.15.3.3 Method to Create or Set Checkpoint String

pbs.checkpoint()

pbs.checkpoint("<checkpoint_string>")

where <*checkpoint_string*> must be one of "*n*", "*s*", "*c*", "*c=mmm*", "*w*", or "*w=mmm*"

Creates an object representing the job Checkpoint attribute, using the specified formatted input string <*checkpoint_string*>.

6.15.3.4 Method to Create or Set Dependency Object

pbs.depend()

pbs.depend("<depend_string>")

<depend_string> must be of format *"<type>:<jobid>[:<jobid>...]"*, or *"on:<count>"*.

where *<type>* is one of "*after*", "*afterok*", "*afterany*", "*afternotok*", "*before*", "*beforeok*", "*beforeany*", and "*beforenotok*".

Creates a PBS dependency specification object representing the job depend attribute, using the given *<depend_string>*.

Usage:

pbs.event().job.depend = pbs.depend("<depend_string>")

6.15.3.5 Method to Create or Set Duration from Time String or Integer

pbs.duration()

pbs.duration("[[hours:]minutes:]seconds[.milliseconds]")

Creates a time specification duration instance, returning the equivalent number of seconds from the given time string. Represents an interval or elapsed time in number of seconds. Duration objects can be specified using either a time or an integer. See "Method to Create or Set Duration from Time String or Integer".

pbs.duration(<integer>)

Creates an integer duration instance using the specified number of seconds.

A pbs.duration instance can be operated on by any of the Python int functions. When performing arithmetic operations on a pbs.duration type, ensure the resulting value is a pbs.duration() type, before assigning to a job member that expects such a type.

Example:

```
pbs.event().job.Resource_List["cput"] = pbs.duration(300 + d1) # safe
```

The following will **not** work, since Python evaluates from left to right, and returns result as the type at left (int):

```
d1 = pbs.duration(30)
pbs.event().job.Resource_List["cput"] = 300  + d1
```

6.15.3.6 Method to Create or Set Email List

pbs.email_list()

pbs.email_list("<email_address1>[, <email address2>...]")

Creates an object representing a mail list from the specified formatted input string.

6.15.3.7 Method to Create or Set exec_host Object

pbs.exec_host()

*pbs.exec_host("host/N[*C][+...]")*

Create an object representing the exec_host job attribute, using the specified input string containing host and resource specification.

6.15.3.8 Method to Create or Set exec_vnode Object

pbs.exec_vnode()

pbs.exec_vnode("<vchunk>[+<vchunk> ...]")

<vchunk> is *(<vnodename:ncpus=N:mem=M>)*

Creates an object representing the exec_vnode job attribute, using the input string containing the vnode and resource specification. When the `qrun -H` command is used, or when the scheduler runs a job, the job.exec_vnode object contains the vnode specification for the job.

Example:

```
pbs.exec_vnode("(vnodeA:ncpus=N:mem=X)+(nodeB:ncpus=P:mem=Y+nodeC:mem=Z)")
```

This object is managed and accessed via the str() or repr() functions. Example:

```
Python> ev = pbs.server().job("10").exec_vnode
Python> str(ev)                "(vnodeA:ncpus=2:mem=200m)+(vnodeB:ncpus=5:mem=1g)"
```

6.15.3.9 Method to Create or Set group_list Object

pbs.group_list()

pbs.group_list("<group_name>[@<host>][,<group_name>[@<host>]...]")

Creates an object representing a PBS group list from the specified formatted input string.

To use a group list object:

```
job.group_list = pbs.group_list(....)
```

6.15.3.10 Method to Create or Set hold_types Object

pbs.hold_types()

pbs.hold_types("<hold_type_str>")

where *<hold_type_str>* is one of "*u*", "*o*", "*s*", or "*n*".

Creates an object representing the Hold_Types job attribute from the specified formatted input string.

6.15.3.11 Method to Create or Set job_sort_formula Object

pbs.job_sort_formula()

pbs.job_sort_formula("<formula string>")

where *<formula string>* is a string containing a math formula. See section 4.9.21, “Using a Formula for Computing Job Execution Priority”, on page 150.

Creates an object representing the job_sort_formula server attribute from the specified formatted input string.

6.15.3.12 Method to Create or Set join_path Object

pbs.join_path()

pbs.join_path({"oe"|"eo"|"n"})

Creates an object representing the Join_Path job attribute from the specified formatted input string.

6.15.3.13 Method to Create or Set keep_files Object

pbs.keep_files()

pbs.keep_files("<Keep_Files option>")

where *<Keep_Files option>* is one of "n", "d", "o", "e", "oe", "eo".

Creates an object representing the Keep_Files job attribute from the specified formatted input string.

6.15.3.14 Method to Create or Set license_count Object

pbs.license_count()

pbs.license_count("Avail_Global:<value> Avail_Local:<value> Used:<value> High_Use:<value>")

Instantiates an object representing a license_count attribute from the specified formatted input string.

6.15.3.15 Method to Create or Set mail_points Object

pbs.mail_points()

pbs.mail_points("<mail points string>")

where *mail points string* is "*a*", "*b*", and/or "*e*", optionally with *"j"*, or "*n*".

Creates a pbs.mail_points object representing a Mail_Points attribute from the specified formatted input string.

6.15.3.16 Method to Create or Set node_group_key Object

pbs.node_group_key()

pbs.node_group_key("<resource(s)>")

Creates a pbs.node_group_key object representing the resource(s) to be used for node grouping, using the specified resource(s). The input string is a comma-separated, quoted list of resources.

6.15.3.17 Method to Create or Set path_list Object

pbs.path_list()

pbs.path_list("<path>[@<host>][,<path>@<host> ...]")

Creates an object representing a PBS pathname list from the specified formatted input string.

To use a path list object:

```
job.Shell_Path_List = pbs.path_list(....)
```

6.15.3.18 Method to Create or Set Job Environment Object

pbs.pbs_env()

Creates an empty environment variable list.

For example, to clear an environment variable list:

```
pbs.event().env = pbs.pbs_env()
```

6.15.3.19 Method to Create or Set Resource List

pbs.pbs_resource()

pbs.pbs_resource(<resource list name>)

Creates a pbs.pbs_resource object with the specified name.

To set values for a pbs.pbs_resource object:

<resource list name>['<resource name>']=<resource value>

For example:

```
Resource_List['ncpus']=8
Resource_List['mem']=pbs.size("10gb")
Resource_List['walltime']=pbs.duration('00:45:00')
```

A pbs.pbs_resource is similar to a dictionary, but you cannot use direct traversal. To loop through entries:

for r in <list name>.keys():

...

For example:

```
for r in <Resource_List>.keys():
    pbs.logmsg(pbs.LOG_DEBUG, "Resource_List[%s]=%s" % (r, Resource_List[r]))
```

which produces the following log message:

```
03/08/2018 18:47:16;0006;pbs_python;Hook;pbs_python;Resource_List[walltime]=00:45:00
03/08/2018 18:47:16;0006;pbs_python;Hook;pbs_python;Resource_List[mem]=10gb
03/08/2018 18:47:16;0006;pbs_python;Hook;pbs_python;Resource_List[ncpus]=7
```

A str(<object of type pbs.pbs_resource>) produces output of the form:

<resource name>=<value>,<resource name>=<value>, ...

To do the equivalent of str():

```
pbs.logmsg(pbs.LOG_DEBUG, "Resource_List is %s (%s)" % (Resource_List, type(Resource_List)))
```

This produces the following log message:

```
03/08/2018 18:47:16;0006;pbs_python;Hook;pbs_python;Resource_List is
    mem=10gb,ncpus=7,walltime=00:45:00 (<class 'pbs.v1._base_types.pbs_resource'>)
```

6.15.3.20 Method to Create or Set place Object

pbs.place()

pbs.place("[arrangement]:[sharing]:[group]")

arrangement can be "*pack*", "*scatter*", "*free*", "*vscatter*"

sharing can be *"shared"*, *"excl", "exclhost"*

group can be of the form "*group=<resource>*"

[arrangement], *[sharing]*, and *[group]* can be given in any order or combination.

Creates a place object representing the job's place specification from the specified formatted input string.

Example:

```
pl = pbs.place("pack:excl")
s = repr(pl)            (or s = `pl`)
letter = pl[0]          (assigns 'p' to letter)
s = s + ":group=host"   (append to string)
pl = pbs.place(s)       (update original pl)
```

6.15.3.21 Method to Create or Set range Object

pbs.range()

pbs.range("<start>-<stop>:<step>")

Creates a PBS object representing a range of values from the specified formatted input string. Can be used to create a job.array_indices_submitted object. See section 6.6.1.2.ii, "Job array_indices_submitted Attribute Member", on page 134.

Example:

```
pbs.range("1-30:3")
```

6.15.3.22 Method to Create or Set route_destinations Object

pbs.route_destinations()

pbs.route_destinations("<queue_spec>[,<queue_spec>,...]")

where *<queue_spec>* is *queue_name[@server_host[:port]]*

Creates an object that represents a route_destinations routing queue attribute from the specified formatted input string.

6.15.3.23 Method to Create or Set select Object

pbs.select()

pbs.select("[N:]res=val[:res=val]...[+[N:]res=val[:res=val] ...]")

Creates a select object representing the job's select specification from the specified formatted input string.

Example:

```
sel = pbs.select("2:ncpus=1:mem=5gb+3:ncpus=2:mem=5gb")
s = repr(sel)                (or s = `sel`)
letter = s[3]                (assigns 'c' to letter)
s = s + "+5:scratch=10gb"    (append to string)
sel = pbs.select(s)          (reset the value of sel)
```

6.15.3.24 Method to Increment select Object Chunks

pbs.select.increment_chunks()

pbs.select.increment_chunks(<increment specification>)

Creates a select object representing the job's new select specification, which has been padded from the original according to the *increment specification.*

You can pad all chunks, but you do not pad the primary vnode request itself; the job can only request one primary vnode. So when a job requests 3:ncpus=8+4:ncpus=1, the non-paddable primary vnode is considered to be a separate request of 1:ncpus=8, and the paddable part is the remaining 2:ncpus=8+4:ncpus=1. :

Table 6-46: Behavior for increment specification

Value of increment specification	Behavior
Integer amount Format: can be with or without quotes (a number or a numeric string), e.g. 5 or "5"	Adds specified number of vnodes to each chunk in the job's vnode request. Examples: Given this initial select statement: my_select=pbs.select("ncpus=3:mem=1gb+1:ncpus=2:mem=2gb+2:ncpus=1:mem=3gb") Calling my_select.increment_chunks(2) returns: "1:ncpus=3:mem=1gb+3:ncpus=2:mem=2gb+4:ncpus=1:mem=3gb" Calling my_select.increment_chunks("3") returns: "1:ncpus=3:mem=1gb+4:ncpus=2:mem=2gb+5:ncpus=1:mem=3gb"
Percentage amount Format: a quoted numeric string ending in a per-cent sign, e.g. "10%"	Adds specified percent of vnodes to each chunk in the job's vnode request. Resulting amounts are rounded up. Example: Given this initial select statement: my_select=pbs.select("ncpus=3:mem=1gb+1:ncpus=2:mem=2gb+2:ncpus=1:mem=3gb") Calling my_select.increment_chunks("23.5%") returns: "1:ncpus=3:mem=1gb+2:ncpus=2:mem=2gb+3:ncpus=1:mem=3gb" The first chunk, which is a single chunk, is left as is, and the second and third chunks are increased by 23.5 %. 1.24 is rounded up to 2, and 2.47 is rounded up to 3.
Per-chunk specification Format: {*<chunk index> : <increment>, ...*} where the increment can be an integer or a per-centage	Adds specified amount or percent to specified chunk(s). Chunk index starts at *0*. Examples: Given this initial select statement: my_select=pbs.select("ncpus=3:mem=1gb+1:ncpus=2:mem=2gb+2:ncpus=1:mem=3gb") Calling my_select.increment_chunks({0: 0, 1: 4, 2: "50%"}) returns: "1:ncpus=3:mem=1gb+5:ncpus=2:mem=2gb+3:ncpus=1:mem=3gb" There is no increase (0) for chunk 1, we give 4 additional chunks to chunk 2, and we increase chunk 3 by 50%, resulting in 3. Given this initial select statement: my_select=pbs.select("5:ncpus=3:mem=1gb+4:ncpus=2:mem=2gb+2:ncpus=1:mem=3gb") Calling my_select.increment_chunks("50%") or my_select.increment_chunks({0: "50%", 1: "50%", 2: "50%}) returns: "7:ncpus=3:mem=1gb+6:ncpus=2:mem=2gb+3:ncpus=1:mem=3gb" The primary vnode is broken out as "1:ncpus=3:mem=1gb" and is left as is. The "50%" increase is applied to the remaining portion, "4:ncpus=3:mem=1gb". After the increase is applied, the original first chunk is re-created from the primary vnode and the padded remains of the first chunk to make 7. Chunk 2 gets 6 and chunk 3 gets 3.

6.15.3.24.i Example of Padding Chunks

The following code snippet illustrates padding a job's vnode request by one extra vnode per chunk:

```
import pbs
e=pbs.event()
j = e.job
new_select = e.job.Resource_List["select"].increment_chunks(1)
e.job.Resource_List["select"] = new_select
```

6.15.3.25 Method to Create or Set size Object

pbs.size()

You can create a pbs.size object using either a byte count or a suffix:

pbs.size(<integer>)

Creates a PBS size object using integer byte count, storing the value as the number of bytes. Size objects can be specified using either an integer or a string. See the "pbs.size("<integer><suffix>")" creation method.

pbs.size("<integer><suffix>")

Creates a PBS size object using the specified suffix. The suffix must be a multiplier defined in the table shown in "Size" on page 360 of the PBS Professional Reference Guide. The size of a word is the word size on the execution host. Size objects can be specified using either an integer or a string.

To operate on pbs.size instances, use the "+" and "-" operators.

To compare pbs.size instances, use the "==", "!=", ">", "<", ">=", and "<=" operators.

Example: the sizes are normalized to the smaller of the 2 suffixes. In this case, "10gb" becomes "10240mb" and is added to "10mb":

```
sz = pbs.size("10gb")
sz = sz + 10mb
10250mb
```

Example: the following returns *True* because sz is greater than 100 bytes:

```
if  sz > 100:
    gt100 = True
```

6.15.3.26 Method to Create or Set Software Resource Object

pbs.software()

pbs.software("<software info string>")

Creates an object representing a site-dependent software resource from the specified formatted input string.

6.15.3.27 Method to Create or Set staging_list Object

pbs.staging_list()

pbs.staging_list("<filespec>[,<filespec>,...]")

where *<filespec>* is *<execution_path>@<storage_host>:<storage_path>*

Creates an object representing a job file staging parameters list from the specified formatted input string.

To use a staging list object:

```
job.stagein = pbs.staging_list(....)
```

6.15.3.28 Method to Create or Set state_count Object

pbs.state_count()

pbs.state_count("Transit:<U> Queued:<V> Held:<W> Running:<X> Exiting:<Y> Begun:<Z>")

Instantiates an object representing a state_count attribute from the specified formatted input string.

6.15.3.29 Method to Create or Set user_list Object

pbs.user_list()

pbs.user_list("<user>[@<host>][,<user>@<host>...]")

Creates an object representing a PBS user list from the specified formatted input string.

To use a user list object:

```
job.User_List = pbs.user_list(....)
```

6.15.3.30 Method to Create or Set PBS Version Object

pbs.version()

pbs.version("<pbs version string>")

Creates an object representing the PBS version string from the specified formatted input string.

6.15.4 Global Methods

We use "global methods" to refer to methods that are global to the module (not to a hook).

6.15.4.1 Method to Get Local Vnode Name

pbs.get_local_nodename()

This returns a Python str whose value is the name of the local parent vnode.

If you want to refer to the vnode object representing the current host, you can pass this vnode name as the key to pbs.event().vnode_list[]. For example:

```
Vn = pbs.event().vnode_list[pbs.get_local_nodename()]
```

6.15.4.2 Method to Log Job-related String

pbs.logjobmsg()

pbs.logjobmsg(job ID, message)

where *job ID* must be an existing or previously existing job ID and where *message* is an arbitrary string.

This puts a custom string in the log of the PBS daemon running the hook, so if the method is being run by a server hook such as queuejob, it prints to the server log, but if the method is being run at an execution host hook such as execjob_prologue, it prints to the MoM log.

The `tracejob` command can be used to print out the job-related messages logged by a hook script.

Messages are logged at log event class pbs.LOG_DEBUG. See Table 6.15.4.4, “Message Log Level Objects,” on page 177.

6.15.4.3 Method to Log String

pbs.logmsg()

pbs.logmsg(log event class, message)

where *message* is an arbitrary string, and where *log event class* can be one of the message log event class constants shown in Table 6-47, “Message Log Level Objects,” on page 177.

This puts a custom string in the log of the PBS daemon running the hook, so if the method is being run by a server hook such as queuejob, it prints to the server log, but if the method is being run at an execution host hook such as execjob_prologue, it prints to the MoM log.

Example:

```
for j in pbs.server().jobs():
   pbs.logmsg(pbs.LOG_DEBUG, "found job %s" % (j.id))
```

6.15.4.4 Message Log Level Objects

You can use the following objects to indicate log level when placing messages in the server logs.

Table 6-47: Message Log Level Objects

Object	Decimal	Hex	PBS Log Event Filter	Name and Event Category
pbs. EVENT_ERROR	1	0x0001	error	PBSEVENT_ERROR Internal errors
pbs. EVENT_SYSTEM	2	0x0002	system	PBSEVENT_SYSTEM system errors
pbs. EVENT_ADMIN	4	0x0004	admin	PBSEVENT_ADMIN Administrative events
pbs.LOG_DEBUG	5	0x0005	admin	PBSEVENT_ADMIN Administrative events
pbs.LOG_WARNING	6	0x0006	admin	PBSEVENT_ADMIN Administrative events
pbs.LOG_ERROR	7	0x0007	admin	PBSEVENT_ADMIN Administrative events
pbs. EVENT_JOB	8	0x0008	job	PBSEVENT_JOB Job-related events
pbs. EVENT_JOB_USAGE	16	0x0010	job_usage	PBSEVENT_JOB_USAGE Job accounting info
pbs. EVENT_SECURITY	32	0x0020	Security	PBSEVENT_SECURITY Security violations
pbs. EVENT_SCHED	64	0x0040	sched	PBSEVENT_SCHED Scheduler events

Table 6-47: Message Log Level Objects

Object	Decimal	Hex	PBS Log Event Filter	Name and Event Category
pbs. EVENT_DEBUG	128	0x0080	debug	PBSEVENT_DEBUG Common debug messages
pbs. EVENT_DEBUG2	256	0x0100	debug2	PBSEVENT_DEBUG2 Uncommon debug messages
pbs. EVENT_RESV	512	0x0200	resv	PBSEVENT_RESV Reservation-related events
pbs. EVENT_DEBUG3	1024	0x0400	debug3	PBSEVENT_DEBUG3 Less common than PBSEVENT_DEBUG2
pbs. EVENT_DEBUG4	2048	0x0800	debug4	PBSEVENT_DEBUG4 Less common than debug3
pbs. EVENT_FORCE	4096	0x8000	(No filter applies)	PBSEVENT_FORCE Forces a message to be logged

6.15.4.5 Method to Reboot Host

pbs.reboot()

pbs.reboot([<command>])

This stops hook execution, so that remaining lines in the hook script are not executed, and starts the tasks that would normally begin after the hook is finished, such as flagging the current host to be rebooted. The MoM logs show the following:

```
<hook name> requested for host to be rebooted
```

We recommend that before calling pbs.reboot(), you set any vnodes managed by this MoM offline, and requeue the current job, if this hook is not an exechost_periodic hook. For example:

```
for  v in pbs.event().vnode_list.keys():
    pbs.event().vnode_list[v].state = pbs.ND_OFFLINE
    pbs.event().vnode_list[v].comment = "Rebooting host"
pbs.event().job.rerun()
pbs.reboot()
```

The effect of the call to pbs.reboot() is not instantaneous. The reboot happens after the hook executes, and after any of the other actions such as pbs.event().job.rerun(), pbs.event().delete(), and pbs.event().vnode_list[] take effect.

A hook with its user attribute set to *pbsuser* cannot successfully invoke pbs.reboot(), even if the owner is a PBS Manager or Operator. If this is attempted, the host is not rebooted, and the following message appears at log event class PBSEVENT_DEBUG2 in the MoM logs:

```
<hook_name>; Not allowed to issue reboot if run as user.
```

The <*command*> is an optional argument. It is a Python str which is executed instead of the reboot command that is the default for the system. For example:

```
pbs.reboot("/usr/local/bin/my_reboot -s 10 -c 'going down in 10'")
```

The specified <*command*> is executed in a shell on Linux/UNIX or via cmd on Windows.

7
Built-in Hooks

7.1 Managing Built-in Hooks

PBS comes shipped with built-in hooks that implement features or patch bugs. You can operate on these hooks via `qmgr`. The `qmgr` keyword for built-in hooks is "*pbshook*". These hooks are named with the "*PBS*" prefix.

7.2 Prerequisites

You can operate on built-in hooks only from an account that has root access to the PBS server host.

When operating on a built-in hook, use the keyword "*pbshook*", not "*hook*".

7.3 Allowed Operations

You can perform a limited set of operations on built-in hooks. You can do the following:

- View attributes
- Set all attributes except for type
- Edit configuration files
- Replace with your own hook

7.4 Viewing Built-in Hooks

You can view attributes of built-in hooks:

```
# qmgr -c "list pbshook"
Hook PBS_example_hook
    type = pbs
    enabled = false
    event = queuejob,resvsub
    user = pbsadmin
    alarm = 90
    order = 1000
```

7.5 Setting Attributes of Built-in Hooks

You can set all attributes except for the type attribute for a built-in hook. For example, you can enable and disable built-in hooks:

```
# qmgr -c "set pbshook <built-in hook name> enabled=true"
# qmgr -c "set pbshook <built-in hook name> enabled=false"
```

If you disable a built-in hook, the following message is printed to qmgr's STDERR:

```
"WARNING: Disabling a PBS hook results in an unsupported configuration!"
```

7.6 Editing and Importing Configuration Files for Built-in Hooks

You can edit and re-import a configuration file for a built-in hook. Get the contents of the configuration file by exporting the file:

```
#qmgr -c "export pbshook <hook name> application/x-config default" > config_file_save
```

Edit the file (here, config_file.save), then re-import it:

```
# qmgr -c "import pbshook <hook name> application/x-config <content-encoding> default
    config_file.save"
```

7.7 Restrictions

- You cannot create or delete a built-in hook. Attempting to do so results in the following error being printed to qmgr's STDERR:
  ```
  Invalid request
  ```
- You cannot import or export content of a built-in hook. Attempting to do so results in the following error being printed to qmgr's STDERR:
  ```
  <content-type> must be application/x-config
  ```
- You cannot display the commands to re-create a built-in hook: using `qmgr -c "print pbshook"` won't work.

7.8 Replacing a Built-in Hook with Your Own Hook

You can replace a built-in hook with your own hook. For example, to replace a built-in exechost_startup hook:

1. Disable the built-in hook:
   ```
   # qmgr -c "set pbshook <built-in startup hook> enabled=false"
   ```
2. Create your own site-defined hook instead:
   ```
   # qmgr -c "create hook <your startup hook> event=exechost_startup"
   # qmgr -c "import hook <your startup hook> application/x-python default <your startup script>
   ```

7.9 Errors and Logging when Operating on Built-in Hooks

- If you try to operate on a built-in hook from an account that does not have root or Admin access, the following error message is issued to STDERR:

  "unable to generate a hook_tempfile from <filepath> - Permission denied"

  <user>@<host> is unauthorized to access hooks data from server <hostname>"

- If you try to import or export a built-in hook, you will see one of the following messages on STDERR:

  # qmgr -c "import pbshook <hook name> application/x-python default my_hook.py"

  <content-type> must be application/x-config

  or

  #qmgr -c "export pbshook <hook name> application/x-python default"

  <content-type> must be application/x-config

8 Debugging Hooks

8.1 The pbs_python Hook Debugging Tool

You can use the pbs_python wrapper that is shipped with PBS to debug hooks. Either:

- Use the --hook option to pbs_python to run pbs_python as a wrapper to Python, employing the pbs_python options. With the --hook option, you cannot use the standard Python options. The rest of this section covers how to use pbs_python with the --hook option.
- Do not use the --hook option, so pbs_python runs the Python interpreter, with the standard Python options, and without access to the pbs_python options.

Usage for pbs_python:

pbs_python --hook [-e <log event mask>] [-i <event input_file>] [-L <log dir>] [-l <log file>] [-o <hook execution record>] [-r <resourcedef file>] [-s site data file] [<python script>]

For a complete description of pbs_python, see "pbs_python" on page 82 of the PBS Professional Reference Guide.

8.2 Files for Debugging

You can get each hook to write out debugging files, and then modify the files and use them as debugging input to pbs_python. Alternatively, you can write the files yourself.

Debugging files can contain information about the event, about the site, and about what the hook changed. You can use these as inputs to a hook when debugging.

8.2.1 Producing Files for Debugging

To get a hook to write out event and site debugging files, and a hook execution record, set its debug attribute to *True* (the default is *False*). The files are named *hook_<event type>_<hook name>_<random integer>.in*, *.data*, and *.out*. The <*random integer*> is the same for all output files for one run of a hook. The <*random integer*> is different for each run.

The hook writes these files:

- *Event file*, containing the values that populate the pbs.event() objects in the hook and any other top level pbs objects like pbs.get_local_nodename(), and job and job list information. This file always contains the event type. The file is named *hook_<event type>_<hook name>_<random integer>.in*. Can be passed to pbs_python using -i <event file> option. See section 8.2.5, "Event File", on page 184.
- *Site data file*, containing the values that populate the pbs.server() objects: server, queue, vnode, etc. information. The site data file is named *hook_<event type>_<hook name>_<random integer>.data*. Can be passed to pbs_python using -s <site data file> option. This file is populated only when the hook calls pbs.server(). See section 8.2.6, "Site Data File", on page 190.
- *Hook execution record*, listing whether the hook accepted or rejected the event, and whatever was changed by the hook, named *hook_<event type>_<hook name>_<random integer>.out*. See section 8.2.7, "Hook Execution Record File", on page 191.

So for example an execjob_begin hook named *BeginHook* will produce files, if PBS chooses "*15223*" as its random integer, named *hook_execjob_begin_BeginHook_15223.in*, *hook_execjob_begin_BeginHook_15223.data*, and *hook_execjob_begin_BeginHook_15223.out*.

8.2.2 Locations for Debugging Files

These files are written to these locations:

- Pre-execution hooks: PBS_HOME/server_priv/hooks/tmp
- All exechost_* and execjob_* hooks: PBS_HOME/mom_priv/hooks/tmp

8.2.3 Format for Debugging Files

File format for debugging files is text. For example:

```
pbs.event().job.Hold_Types=u
pbs.event().job.Job_Name=STDIN
pbs.event().job.Checkpoint=u
pbs.event().job.Join_Path=n
pbs.event().job.Keep_Files=n
pbs.event().job.Mail_Points=a
pbs.event().job.Priority=0
pbs.event().job.Rerunable=TRUE
pbs.event().job.Resource_List[ncpus]=5
pbs.event().job.Resource_List[mem]=2gb
pbs.get_local_nodename()=mars.example.com
pbs.event().type=queuejob
pbs.event().hook_name=qjob
pbs.event().hook_type=site
pbs.event().requestor=TestUser
pbs.event().requestor_host=mars.example.com
pbs.event().user=pbsadmin
pbs.event().alarm=30
```

8.2.4 Time Limit for Debugging Files

PBS deletes hook .in, .data, and .out files in PBS_HOME/*/hooks/tmp that are older than 20 minutes. If you need to keep any of these files, copy them to another location.

8.2.5 Event File

The event file must contain the event type, and can contain any relevant information about the triggering event, the current job, or list of jobs.

When the hook writes it, this file contains the values that populate the pbs.event() objects in the hook and any other top level pbs objects such as the local vnode, the job, and the list of jobs. When a hook writes this file, it includes pbs.event().type and the result of get_local_nodename(). Each kind of hook writes different additional pbs.event() information.

The file is named *hook_<event type>_<hook name>_<random integer>.in*. It can be passed to `pbs_python` using the `-i <event file>` option.

The following tables show which information is written to the event file by each kind of hook:

Table 8-1: Event File by Hook, for Job Hooks

Event Information Written by Hooks: pbs.event.<list item>	provision	queuejob	postqueuejob	movejob	modifyjob (before run)	runjob (on reject)	runjob (on accept)	jobobit	execjob_begin	execjob_prologue	execjob_launch	execjob_attach	execjob_postsuspend	execjob_preresume	execjob_preterm	execjob_epilogue	execjob_end
pbs.get_local_nodename()		y	y	y	y	y	y	y	y	y	y	y	y	y	y	y	y
alarm		y	y	y	y	y	y	y	y	y	y	y	y	y	y	y	y
argv[]											y	y					
env											y	y					
freq

resv.Variable_List	y	y	y	y	y					

Table 8-2: Event File by Hook, for Non-job Hooks

Event Information Written by Hooks: pbs.event.<list item>	resvsub	resv_confirm	modifyresv	resv_begin	resv_end	management	periodic	modifyvnode	exechost_startup	exechost_periodic
type	y	y	y	y	y	y	y	y	y	y
user	y	y	y	y	y	y	y	y	y	y
vnode_list["<local vnode name>"].pbs_version										y
vnode_list["<local vnode name>"].pcpus										y
vnode_list["<local vnode name>"].resources_assigned[mem]										
vnode_list["<local vnode name>"].resources_assigned[ncpus]										
vnode_list["<local vnode name>"].resources_available[arch]										y
vnode_list["<local vnode name>"].resources_available[file]										y
vnode_list["<local vnode name>"].resources_available[mem]									y	y
vnode_list["<local vnode name>"].resources_available[ncpus]									y	y

For example, an event file created by a queuejob hook contains this data:

```
pbs.get_local_nodename()=jupiter.example.com
pbs.event().type=queuejob
pbs.event().hook_name=qjob
pbs.event().hook_type=site
pbs.event().requestor=TestUser
pbs.event().requestor_host=jupiter.example.com
pbs.event().user=pbsadmin
pbs.event().alarm=30
```

The equivalent command is:

```
Qmgr: list hook
```

8.2.5.1 Caveats

When the execjob_epilogue or execjob_end hook writes resources such as resources_used to the event file, it is writing about only the resources on the local host.

8.2.6 Site Data File

The site data file can contain any relevant information about the server, queues, vnodes, and jobs at the server.

This file is populated only when the hook calls pbs.server().

When the hook writes it, this file contains the values that populate the server, queues, vnodes, reservations, and jobs, with all attributes and resources for which there are values.

The site data file is named *hook_<event type>_<hook name>_<random integer>.data*. It can be passed to `pbs_python` using the `-s <site data file>` option.

The following commands give equivalent information:

```
qstat -Bf
qstat -Qf
qstat -f
pbsnodes -av
```

For example, here are some representative parts of a site data file:

```
pbs.server().scheduling=True
pbs.server().total_jobs=2
pbs.server().state_count=Transit:0 Queued:0 Held:2 Waiting:0 Running:0 Exiting:0 Begun:0
...
ppbs.server().default_chunk[ncpus]=1
pbs.server().resources_assigned[mem]=0mb
pbs.server().resources_assigned[ncpus]=0
...
pbs.server().job(501.jupiter.example.com).Job_Owner=TestUser@jupiter.example.com
pbs.server().job(501.jupiter.example.com).job_state=H
pbs.server().job(501.jupiter.example.com).queue=workq
...
pbs.server().job(501.jupiter.example.com).Resource_List[ncpus]=1
pbs.server().job(501.jupiter.example.com).Resource_List[place]=pack
...
pbs.server().queue(workq).queue_type=Execution
pbs.server().queue(workq).total_jobs=2
pbs.server().queue(workq).resources_assigned[mem]=0mb
pbs.server().queue(workq).resources_assigned[ncpus]=0
```

8.2.7 Hook Execution Record File

The hook execution record file is produced when the hook runs. This file lists the following:

- Whether the event was accepted or rejected
- Any job values that were changed by the hook, showing the new values

This file is named *hook_<event type>_<hook name>_<random integer>.out*.

8.3 Steps to Debug a Hook Using pbs_python

When you debug a hook using `pbs_python`, give it the following information:

- Use the `--hook` option to `pbs_python` so that you can use the other `pbs_python` options
- Specify event information by using `-i <event file>`. At a minimum, include the type of the event, but you can also include job and job list information. Information about the event can be one of these:
  - An event information file (`.in`) written by the hook
  - A file written by you
  - Interactive input

See section 8.2.5, "Event File", on page 184.

- Optionally, provide site data. Site data includes data about the server, queues, vnodes, etc. You specify site data in a file by using `-s <site data file name>`. If you do not specify the `-s` option, `pbs_python` connects to the server and obtains live data about the site. See section 8.2.6, "Site Data File", on page 190. Site data can come from one of these sources:
  - A site data file (`.data`) written by the hook
  - A file written by you
  - Interactive input
  - Live data from the server
- If you have added any custom resources, specify the `PBS_HOME/server_priv/resourcedef` file with the `-r` option to `pbs_python`. Make sure you specify the whole path to the file. For example:

  ```
  pbs_python --hook -r $PBS_HOME/server_priv/resourcedef -i <input_file> <hook.py>
  ```
- If your hook uses a configuration file, set the environment variable PBS_HOOK_CONFIG_FILE to the file's pathname before calling `pbs_python`. See section 5.1.6, "Using Hook Configuration Files", on page 33.
- Run `pbs_python` on the hook:

  ```
  pbs_python --hook -s <site data> -i <event file> <hook script>
  ```

8.4 Caveats and Restrictions for pbs_python

- When you run a hook inside `pbs_python`, it has access to the extended set of `PBS_EXEC/python` modules listed in section 4.5, "Python Modules and PBS", on page 25. When you run `pbs_python` at the command line (without `--hook`), the hook does not have access to the `PBS_EXEC/lib` set of modules.
- If PBS has attempted to run a job multiple times in the 20 minute window, you may need to check the timestamp of hook debugging files (e.g. `ls -lt`) to figure out which files were produced during a particular hook run.
- The site data file is populated only when the hook calls pbs.server().

8.5 Examples of Using pbs_python to Debug Hooks

Example 8-1: Basic periodic hook, with updates to vnodes:

- Input file:

```
% cat hook.input
pbs.event().type=exechost_periodic
pbs.event().vnode_list["host1"].state=free
pbs.get_local_nodename()=host1
```

- Hook file:

```
$ cat test.py
import pbs

e = pbs.event()

pbs.event().vnode_list[pbs.get_local_nodename()].resources_available["ncpus"]=7
pbs.event().vnode_list[pbs.get_local_nodename()].resources_available["mem"]=pbs.size("7gb")
```

- Run:

```
$ pbs_python --hook -i hook.input test.py
pbs.event().accept=True
pbs.event().reject=False
pbs.event().vnode_list["host1"].resources_available[ncpus]=7
pbs.event().vnode_list["host1"].resources_available[mem]=7gb
```

Example 8-2: A queuejob hook:

- Input file:

```
$ cat qjob.input
pbs.event().hook_name=qjob
pbs.event().hook_type=site
pbs.event().type=queuejob
pbs.event().requestor=user1
pbs.event().requestor_host=host1
pbs.event().alarm=40
pbs.event().job.Job_Name=pact
pbs.event().job.Resource_List[ncpus]=1
pbs.event().job.Resource_List[mem]=1mb
```

- Hook file:

```
$ cat qjob.py
import pbs

e = pbs.event()

e.job.Priority = 7
e.job.Account_Name = "mammoth"
e.job.Resource_List["ncpus"] = 5
```

```
e.job.Resource_List["mem"] = pbs.size("5gb")
```

- Run:

```
% pbs_python --hook -i qjob.input qjob.py
pbs.event().accept=True
pbs.event().reject=False
pbs.event().job.Priority=7
pbs.event().job.Resource_List[ncpus]=5
pbs.event().job.Resource_List[mem]=5gb
pbs.event().job.Account_Name=mammoth
```

Example 8-3: Reservation hook:

- Input file:

```
% cat rsub.input
pbs.event().hook_name=qjob
pbs.event().hook_type=site
pbs.event().type=resvsub
pbs.event().requestor=user1
pbs.event().requestor_host=host1
pbs.event().alarm=40
pbs.event().resv.Reserve_Name=my_resv
pbs.event().resv.Resource_List[ncpus]=1
pbs.event().resv.Resource_List[mem]=1mb
```

- Hook file:

```
% cat rsub.py
import pbs

def print_attribs(pbs_obj):
    for a in pbs_obj.attributes:
        v = getattr(pbs_obj, a)
        if v and str(v) != "":
            pbs.logmsg(pbs.LOG_DEBUG, "%s = %s" % (a,v))

e = pbs.event()
r = e.resv

print_attribs(r)

r.Resource_List["select"] = pbs.select("1:ncpus=1:mem=5mb")
r.Resource_List["place"] = pbs.place("pack:shared")

# group_list = pbs.group_list
r.group_list = pbs.group_list("Everyone,Everyone@host2,group1@jobim")

# Mail_Points= pbs.mail_points
r.Mail_Points = pbs.mail_points("a")
```

```
# User_List = pbs.user_list
r.User_List =  pbs.user_list("pbstest,pbstest@host2")

# Authorized_Users = pbs.acl
r.Authorized_Users =  pbs.acl("pbstest,user1,Administrator")

# Authorized_Groups = pbs.acl
r.Authorized_Groups =  pbs.acl("Everyone,group1,group2")
```

- Run:

```
% pbs_python  --hook -i rsub.input rsub.py
pbs.event().accept=True
pbs.event().reject=False
pbs.event().resv.group_list=Everyone,Everyone@host2,group1@jobim
pbs.event().resv.User_List=pbstest,pbstest@host2
pbs.event().resv.Resource_List[select]=1:ncpus=1:mem=5mb
pbs.event().resv.Resource_List[place]=pack:shared
pbs.event().resv.Mail_Points=a
pbs.event().resv.Authorized_Users=pbstest,user1,Administrator
pbs.event().resv.Authorized_Groups=Everyone,group1,group2
```

Example 8-4: A modifyjob hook:

- Hook script:

```
$ cat modifyjob.py

import pbs

def print_attribs(pbs_obj):
    for a in pbs_obj.attributes:
        v = getattr(pbs_obj, a)
        if v and str(v) != "":
            pbs.logmsg(pbs.LOG_DEBUG, "%s = %s" % (a,v))

e = pbs.event()

pbs.logmsg(pbs.LOG_DEBUG, "------> printing job %s" % (e.job_o.id))
print_attribs(e.job_o)
e.job.Priority = 5
e.job.Resource_List["file"] = pbs.size("7gb")
e.job.Variable_List["FILE"] = "7gb"
```

- Use the `pbs_python` debugging tool.

Ensure you have the following input file:

```
% cat hook.input
pbs.event().type=modifyjob
pbs.event().job.id=0.host1
pbs.event().job.Variable_List=A=b
```

- Run the hook:

```
% pbs_python --hook -i hook.input modifyjob.py
```

- The following are printed:

```
pbs.event().accept=True
pbs.event().reject=False

pbs.event().job.Variable_List=A=b,FILE=7gb
pbs.event().job.Priority=5
pbs.event().job.Resource_List[file]=7gb
```

- The `pbs_python` log file shows this:

```
% cat <yyyymmdd>

01/05/2013 07:50:41;0006;pbs_python;Hook;pbs_python;----------------> printing job 0.host1

01/05/2013 07:50:41;0006;pbs_python;Hook;pbs_python;Job_Owner = user1@host1.example.com
```

Example 8-5: A movejob hook which prints job ID, src_queue, and movejob event parameters, and sets src_queue:

- Hook script:

```
$ cat movejob.py

import pbs

def print_attribs(pbs_obj):
    for a in pbs_obj.attributes:
        v = getattr(pbs_obj, a)
        if v and str(v) != "":
            pbs.logmsg(pbs.LOG_DEBUG, "%s = %s" % (a,v))

e = pbs.event()

pbs.logmsg(pbs.LOG_DEBUG, "----------------> printing src_queue %s" % (e.src_queue.name))
print_attribs(e.src_queue)
pbs.logmsg(pbs.LOG_DEBUG, "----------------> printing job %s" % (e.job.id))
print_attribs(e.job)
e.job.queue = pbs.server().queue("workq2")
```

- Use the pbs_python debugging tool:

```
Use the following input file:
% cat hook.input2
pbs.event().type=movejob
pbs.event().job.id=<existing-job-id>
```

where <existing-job-id> must be some arbitrary job currently existing in the queue *workq*. Submit one (`qsub -h`) if it doesn't exist.

- Run the hook:

  % pbs_python --hook -i hook.input2 movejob.py

- The following is printed:

  pbs.event().accept=True

  pbs.event().reject=False

  pbs.event().src_queue=workq2

- The `pbs_python` log file shows this:

  % cat <yyyymmdd>

```
01/05/2013 11:23:36;0006;pbs_python;Hook;pbs_python;----------------> printing
src_queue workq
01/05/2013 11:23:36;0006;pbs_python;Hook;pbs_python;name = workq
01/05/2013 11:23:36;0006;pbs_python;Hook;pbs_python;----------------> printing

```

Example 8-6: A runjob hook to print attributes:

- Hook script:

```
$ cat runjob.py

import pbs
import time

def print_attribs(pbs_obj):
    for a in pbs_obj.attributes:
        v = getattr(pbs_obj, a)
        if v and str(v) != "":
            pbs.logmsg(pbs.LOG_DEBUG, "%s = %s" % (a,v))

e = pbs.event()

pbs.logmsg(pbs.LOG_DEBUG, "----------------> printing job %s" % (e.job.id))
print_attribs(e.job)
e.job.Hold_Types = pbs.hold_types("us")
e.job.Execution_Time = time.mktime([15, 11, 28, 14, 10, 15, -1, -1, 01])
e.job.project="looper"

pbs.event().reject("not allowed to run at this time!")
```

- Use the following input file:

```
% cat hook.input3
pbs.event().type=runjob
pbs.event().job.id=<existing-job-id>
```

where <*existing-job-id*> must be some arbitrary job currently existing in the server. Submit one (`qsub -h`) if it doesn't exist.

- Run the hook:

  `# pbs_python --hook -i hook.input3 runjob.py`

- The execution record contains the following:

  ```
  pbs.event().reject=True
  pbs.event().accept=False
  pbs.event().reject_msg=not allowed to run at this time!
  pbs.event().job.Execution_Time=1448745015
  pbs.event().job.Hold_Types=us
  pbs.event().job.project=looper
  ```

- The `pbs_python` log file shows:

  ```
  % cat <yyyymmdd>

  01/05/2013 14:49:39;0006;pbs_python;Hook;pbs_python;----------------> printing

user1@host1.example.com
```

8.6 Using Log Messages to Debug Hook Scripts

The following steps may help you avoid errors in hook scripts:

1. Create a hook, and import its content.
2. Temporarily set the server's log_events to a higher value such as *2047* to see plenty of logging.
3. Do a test run of the hook script, by causing events (e.g. `qsub`, `qalter`, `qmove`, `pbs_rsub`) that invoke the hook script. Check for error messages in the server logs.
4. Correct the hook script, re-import the fixed code, and rerun the test.
5. Once the hook script is running fine, then set the server's log_events back to the default (i.e. *511*).

8.7 Checking Hook Syntax using Python

You can check hook syntax using Python. If you run Python on the hook, the hook cannot import the pbs module. If the first error you see is a failure to import the pbs module, Python did not find any syntax errors.

8.8 Examples of Debugging Files

Example 8-7: We show several hooks and their debugging files. Our example hooks are queuejob, exechost_startup, exechost_periodic, execjob_begin, and execjob_launch.

Given the following two jobs in the system:

```
TestUser@jupiter:~/jobs> qstat
Job id            Name             User              Time Use S Queue
----------------  ---------------- ----------------  -------- - -----
501.jupiter          STDIN            TestUser                 0 H workq
502.jupiter          STDIN            TestUser                 0 H workq
```

Given the following reservations:

```
TestUser@jupiter:~/jobs> pbs_rstat
Resv ID    Queue    User     State             Start / Duration / End
--------------------------------------------------------------------
R503.jupiter. R503     TestUser@ CO          Today 08:00 / 1800 / Today 08:30
R504.jupiter. R504     TestUser@ CO          Today 09:00 / 1800 / Today 09:30
```

Given the following set of vnodes:

```
TestUser@jupiter:~/jobs> pbsnodes -av
jupiter
    Mom = jupiter.example.com
    Port = 15002
    pbs_version = PBSPro_10.0
    ntype = PBS
    state = free
    pcpus = 1
    resv = R504.jupiter.example.com, R503.jupiter.example.com
    resources_available.arch = linux
    resources_available.host = jupiter
    resources_available.mem = 8gb
    resources_available.ncpus = 8
    resources_available.vnode = jupiter
    resources_assigned.mem = 0kb
    resources_assigned.ncpus = 0
    resources_assigned.vmem = 0kb
    resv_enable = True
    sharing = default_shared
mars
    Mom = mars.example.com
    Port = 15002
    pbs_version = PBSPro_10.0
    ntype = PBS
    state = free
    pcpus = 1
    resources_available.arch = linux
    resources_available.host = mars
    resources_available.mem = 8gb
    resources_available.ncpus = 8
    resources_available.vnode = mars
    resources_assigned.mem = 0kb
    resources_assigned.ncpus = 0
    resources_assigned.vmem = 0kb
    resv_enable = True
    sharing = default_shared
```

queuejob hook attributes:

```
Hook qjob
    type = site
    enabled = true
    event = queuejob
    user = pbsadmin
    alarm = 30
    order = 1
    debug = true
    fail_action = none
```

queuejob hook contents:

```
import pbs
e=pbs.event()

e.job.Priority=7
e.job.Resource_List["file"] = pbs.size("7gb")

s=pbs.server()
for j in s.jobs():
    pbs.logmsg(pbs.LOG_DEBUG, "got j %s" % (j.id,))

for q in s.queues():
    pbs.logmsg(pbs.LOG_DEBUG, "got q %s" % (q.name,))

for v in s.vnodes():
    pbs.logmsg(pbs.LOG_DEBUG, "got vnode %s" % (v.name,))

for r in s.resvs():
    pbs.logmsg(pbs.LOG_DEBUG, "got resv %s" % (r.resvid))
```

Submit the job:

```
% qsub job.scr
```

Here are the resulting *.in, *.data, and *.out files:

```
jupiter:/var/spool/PBS/mom_priv/hooks/tmp # ls -ltr /var/spool/PBS/server_priv/hooks/tmp
-rw-r--r-- 1 root root   241 Sep 17 03:54 hook_queuejob_qjob_1410940476.in
-rw-r--r-- 1 root root 18619 Sep 17 03:54 hook_queuejob_qjob_1410940476.data
-rw-r--r-- 1 root root   805 Sep 17 03:54 hook_queuejob_qjob_1410940476.out
```

List the queuejob hook event file:

```
jupiter:/var/spool/PBS/server_priv/hooks/tmp # cat hook_queuejob_qjob_1410940476.in
pbs.get_local_nodename()=jupiter.example.com
pbs.event().type=queuejob
pbs.event().hook_name=qjob
pbs.event().hook_type=site
pbs.event().requestor=TestUser
pbs.event().requestor_host=jupiter.example.com
pbs.event().user=pbsadmin
pbs.event().alarm=30
```

List the queuejob hook site data file:

```
jupiter:/var/spool/PBS/server_priv/hooks/tmp # cat hook_queuejob_qjob_1410940476.data

```

List the queuejob hook execution record file:

```
jupiter:/var/spool/PBS/server_priv/hooks/tmp # cat hook_queuejob_qjob_1410940476.out
pbs.event().job.Rerunable=1
pbs.event().job.Variable_List=PBS_O_SYSTEM=Linux,PBS_O_SHELL=/bin/bash,PBS_O_HOME=/home/TestUser
    ,PBS_O_LOGNAME=TestUser,PBS_O_WORKDIR=/home/TestUser/jobs,PBS_O_LANG=en_US.UTF-8,PBS_O_PATH=
    /usr/local/bin:/usr/local/bin:/usr/local/bin:/usr/lib64/mpi/gcc/openmpi/bin:/home/TestUser/b
    in:/usr/local/bin:/usr/bin:/bin:/usr/bin/X11:/usr/X11R6/bin:/usr/games:/opt/pbs/bin:/opt/pbs
    /bin:/opt/pbs/bin,PBS_O_MAIL=/var/spool/mail/TestUser
pbs.event().job.Checkpoint=u
pbs.event().job.Submit_arguments=<jsdl-hpcpa:Argument>job.scr</jsdl-hpcpa:Argument>
pbs.event().job.Job_Name=job.scr
pbs.event().job.Mail_Points=a
pbs.event().job.Priority=7
pbs.event().job.Hold_Types=n
pbs.event().job.Join_Path=n
pbs.event().job.Resource_List[file]=7gb
pbs.event().job.Keep_Files=n
```

The exechost_startup hook attributes:

```
Hook start
    type = site
    enabled = true
    event = exechost_startup
    user = pbsadmin
    alarm = 30
    order = 1
    debug = true
    fail_action = none
```

The exechost_startup hook contents:

```
import pbs
e=pbs.event()

e.vnode_list[pbs.get_local_nodename()].resources_available["file"] = pbs.size("7gb")

s=pbs.server()
for j in s.jobs():
    pbs.logmsg(pbs.LOG_DEBUG, "got j %s" % (j.id,))

for q in s.queues():
    pbs.logmsg(pbs.LOG_DEBUG, "got q %s" % (q.name,))

for v in s.vnodes():
    pbs.logmsg(pbs.LOG_DEBUG, "got vnode %s" % (v.name,))

for r in s.resvs():
    pbs.logmsg(pbs.LOG_DEBUG, "got resv %s" % (r.resvid))
```

Restart pbs_mom. Upon startup, the exechost_startup hook writes the following files:

```
jupiter:/home/TestUser/jobs # cd /var/spool/PBS/mom_priv/hooks/tmp
jupiter:/var/spool/PBS/mom_priv/hooks/tmp # ls -ltr
total 24
-rw-r--r-- 1 root root   455 Sep 17 04:02 hook_exechost_startup_start_11607.in
-rw-r--r-- 1 root root   115 Sep 17 04:02 hook_exechost_startup_start_11607.out
-rw-r--r-- 1 root root 12389 Sep 17 04:02 hook_exechost_startup_start_11607.data
```

List the exechost_startup hook event file:

```
jupiter:/var/spool/PBS/mom_priv/hooks/tmp # cat hook_exechost_startup_start_11607.in
pbs.event().vnode_list["jupiter"].resources_available[mem]=757388kb

```

List the exechost_startup hook execution record file:

```
jupiter:/var/spool/PBS/mom_priv/hooks/tmp # cat hook_exechost_startup_start_11607.out
pbs.event().accept=True
pbs.event().reject=False
pbs.event().vnode_list["jupiter"].resources_available[file,size]=7gb
```

The exechost_periodic hook attributes:

```
Hook period
    type = site
    enabled = true
    event = exechost_periodic
    user = pbsadmin
    alarm = 30
    freq = 30
    order = 1
    debug = true
    fail_action = none
```

The contents of the exechost_periodic hook:

```
jupiter:/home/TestUser/jobs # qmgr -c "e h period application/x-python default"
import pbs
e=pbs.event()

e.vnode_list[pbs.get_local_nodename()].resources_available["file"] = pbs.size("7gb")

s=pbs.server()
for j in s.jobs():
    pbs.logmsg(pbs.LOG_DEBUG, "got j %s" % (j.id,))

for q in s.queues():
    pbs.logmsg(pbs.LOG_DEBUG, "got q %s" % (q.name,))

for v in s.vnodes():
    pbs.logmsg(pbs.LOG_DEBUG, "got vnode %s" % (v.name,))

for r in s.resvs():
    pbs.logmsg(pbs.LOG_DEBUG, "got resv %s" % (r.resvid))
```

In our example, we have two jobs running on the execution host:

```
jupiter:/var/spool/PBS/mom_priv/hooks/tmp # qstat
Job id         Name        User        Time Use  S Queue
------------   ----------- ----------- --------  - -----
501.jupiter       STDIN       TestUser      0        H workq
502.jupiter       STDIN       TestUser      0        H workq
506.jupiter       STDIN       TestUser      00:00:00 R workq
507.jupiter       STDIN       TestUser      00:00:00 R workq
```

The *.in, *.out, and *.data files end up here:

```
jupiter:/var/spool/PBS/mom_priv/hooks/tmp # ls -ltr
-rw-r--r-- 1 root root  6885 Sep 17 04:09 hook_exechost_periodic_period_11753.in
-rw-r--r-- 1 root root  1387 Sep 17 04:09 hook_exechost_periodic_period_11753.out
-rw-r--r-- 1 root root 19039 Sep 17 04:09 hook_exechost_periodic_period_11753.data
```

List the exechost_periodic event file:

```
jupiter:/var/spool/PBS/mom_priv/hooks/tmp # cat hook_exechost_periodic_period_11753.in

pbs.event().job_list["507.jupiter.example.com"]._delete=False
pbs.event().job_list["507.jupiter.example.com"]._rerun=False
```

Attributes of the execjob_begin hook:

```
Hook begin
    type = site
    enabled = true
    event = execjob_begin
    user = pbsadmin
    alarm = 30
    order = 1
    debug = true
    fail_action = none
```

Contents of the execjob_begin hook:

```
import pbs
e=pbs.event()

e.job.Priority=7
e.job.Variable_List["Monsieur"] = "Shlomi"

s=pbs.server()
for j in s.jobs():
    pbs.logmsg(pbs.LOG_DEBUG, "got j %s" % (j.id,))

for q in s.queues():
    pbs.logmsg(pbs.LOG_DEBUG, "got q %s" % (q.name,))

for v in s.vnodes():
    pbs.logmsg(pbs.LOG_DEBUG, "got vnode %s" % (v.name,))

for r in s.resvs():
    pbs.logmsg(pbs.LOG_DEBUG, "got resv %s" % (r.resvid))
```

We submit a job:

```
% qsub job.scr
```

The resulting execjob_begin debug files are here:

```
jupiter:/var/spool/PBS/mom_priv/hooks/tmp # ls -ltr
-rw-r--r-- 1 root root  2263 Sep 17 04:15 hook_execjob_begin_begin_11883.in
-rw-r--r-- 1 root root   585 Sep 17 04:15 hook_execjob_begin_begin_11883.out
-rw-r--r-- 1 root root 15327 Sep 17 04:15 hook_execjob_begin_begin_11883.data
```

```

List the execjob_begin hook execution record file:

```
jupiter:/var/spool/PBS/mom_priv/hooks/tmp # cat hook_execjob_begin_begin_11883.out
pbs.event().accept=True
pbs.event().reject=False
pbs.event().job.Variable_List=PBS_O_SYSTEM=Linux,PBS_O_SHELL=/bin/bash,Monsieur=Shlomi,PBS_O_HOM
    E=/home/TestUser,PBS_O_HOST=jupiter.example.com,PBS_O_LOGNAME=TestUser,PBS_O_WORKDIR=/home/T
    estUser/jobs,PBS_O_LANG=en_US.UTF-8,PBS_O_QUEUE=workq,PBS_O_MAIL=/var/spool/mail/TestUser,PB
    S_O_PATH=/usr/local/bin:/usr/local/bin:/usr/local/bin:/usr/lib64/mpi/gcc/openmpi/bin:/home/T
    estUser/bin:/usr/local/bin:/usr/bin:/bin:/usr/bin/X11:/usr/X11R6/bin:/usr/games:/opt/pbs/bin
    :/opt/pbs/bin:/opt/pbs/bin
pbs.event().job.Priority=7
```

Attributes of the execjob_launch hook:

```
Hook launch
    type = site
    enabled = true
    event = execjob_launch
    user = pbsadmin
    alarm = 30
    order = 1
    debug = true
    fail_action = none
```

Contents of the execjob_launch hook:

```
import pbs
e=pbs.event()

e.progname = "/bin/sleep"
e.argv[1] = "30"

s=pbs.server()
for j in s.jobs():
    pbs.logmsg(pbs.LOG_DEBUG, "got j %s" % (j.id,))

for q in s.queues():
    pbs.logmsg(pbs.LOG_DEBUG, "got q %s" % (q.name,))

for v in s.vnodes():
    pbs.logmsg(pbs.LOG_DEBUG, "got vnode %s" % (v.name,))

for r in s.resvs():
    pbs.logmsg(pbs.LOG_DEBUG, "got resv %s" % (r.resvid))
```

Submit a job:

```
% qsub job.scr
```

The execjob_launch hook writes the *.in, *.data, and *.out files in /var/spool/PBS/spool:

```
jupiter:/var/spool/PBS/spool # ls -ltr /var/spool/PBS/spool
-rw------- 1 TestUser users  3489 Sep 17 04:24 hook_execjob_launch_launch_12135.in
-rw------- 1 TestUser users  1045 Sep 17 04:24 hook_execjob_launch_launch_12135.out
-rw------- 1 TestUser users 15906 Sep 17 04:24 hook_execjob_launch_launch_12135.data
```

List the execjob_launch hook event file:

```
cat hook_execjob_launch_launch_12135.in

    sr/lib64/mpi/gcc/openmpi/bin:/home/TestUser/bin:/usr/local/bin:/usr/bin:/bin:/usr/bin/X11:/u
    sr/X11R6/bin:/usr/games:/opt/pbs/bin:/opt/pbs/bin:/opt/pbs/bin,LOGNAME=TestUser,PBS_TASKNUM=
    1,TZ=US/Eastern
```

8.9 Interactive Debugging using pbs_python

You can perform interactive debugging by leaving out the hook name and supplying event input information and/or site data information. For example, to interactively debug with event input and site data information:

```
pbs_python --hook -i MyEventInputFile -s MySiteData
```

You get a pbs_python prompt, and in order to end the session, issue a pbs.event().accept() or pbs.event().reject():

```
>>import pbs
>>print pbs.event().job.id
1234.examplehost
>>pbs.event().accept()
```

8.10 Error Reporting and Logging

Hook errors are printed to stderr for the command (qsub, qalter, pbs_rsub, or qmove) that triggered the hook. If the hook provides a custom error message, that message is treated the same way.

Hooks can log custom strings to the log file of the daemon from which the hook is executing. When logging a message, a hook uses message logging methods to specify the message, and constant objects to specify the log event class. See "pbs.logmsg()" on page 177, and section 6.15.4.4, "Message Log Level Objects", on page 177.

When the PBS server starts, it prints to the server logs both the Python version integrated with the server, and a list of all the hook names registered with the server.

To see only hook-related 0x0400 messages in the MoM logs, such as "<hook name>;started", "<hook_name>;finished", set the $logevent MoM parameter to *0x400* in the MoM configuration file.

To see all the different types of MoM log messages, set $logevent to *0xffff*.

The default value for the $logevent MoM parameter is *975*, so that the following log events are captured. See "Log Levels" on page 375 of the PBS Professional Reference Guide for more about log levels.

8.10.1 Errors During Creation and Deployment

8.10.1.1 Hook Name Matches Existing Hook

Creating a hook whose name matches that of an existing hook: the following error message is printed in stderr and in the server logs:

"hook error: hook name <hook_name> already registered, try another name"

8.10.1.2 Using a Hook Name that Starts with "*PBS*"

Using a hook name that starts with "*PBS*": the hook name is rejected with the following error in qmgr's stderr, as well as in the server logs:

"hook error: cannot use PBS as a prefix - it is reserved for PBS hooks"

8.10.1.3 Deleting a Non-Existent Hook

Deleting a non-existent hook: the following is returned in qmgr's stderr and server logs:

"qmgr: hook error: <non-existent hook name> does not exist"

8.10.1.4 Specifying a Non-Existent Event Type

Specifying a non-existent event type: an error message is printed to qmgr's stderr and also to the server logs:

Example:

```
Qmgr: set hook hook1 event="mom_checkpoint"
"hook error: invalid argument to event. Should be one of: queuejob, modifyjob, resvsub, movejob,
   runjob, provision, execjob_begin, execjob_prologue, execjob_epilogue, execjob_preterm,
   execjob_end, exechost_periodic, execjob_launch, exechost_startup, execjob_attach or "" for no
   event."
"qmgr: hook error returned from server"
```

8.10.1.5 Using a Bad Hook Value

Putting in a bad hook value: an error is printed to qmgr's stderr and also to the server logs:

Example:

```
Qmgr: set hook hook2 order=1025
"qmgr obj=hookA svr=default: order given (1025) is outside the acceptable range of [1, 1000] for
   type 'site'."
"qmgr: hook error returned from server"
```

8.10.1.6 Unauthorized User

If qmgr is invoked, and the object being operated on is "*hook*", and the executing user at some host does not have access to the target server's private location for hooks data, then the following error is issued to stderr and server logs:

"<user>@<host> is unauthorized to access hooks data from server <hostname>"

8.10.1.7 Setting a Bad Hook Type

Setting a bad type to a hook produces the following error message in qmgr's stderr and also in the server logs:

"hook error: invalid argument to type. Must be site"

8.10.1.8 Setting a Bad Alarm Value

Setting a bad alarm value to a hook produces the following error message in qmgr's stderr and also in the server logs:

"hook error: alarm value of a hook must be > 0"

8.10.1.9 Exporting To Non-Writable File

Exporting a hook's content to a file that is not writable due to ownership or permission problems results in the following error message being printed to stderr:

"qmgr: hook error: <output_file> permission denied"

8.10.1.10 Setting Bad Hook user Attribute

Setting a value for the user attribute of a hook to something other than "*pbsadmin*" produces the following error message in qmgr's stderr and also in the server logs:

"hook error: user value of a hook must be pbsadmin, pbsuser"

This attribute does not need to be set to the actual name of the PBS service account.

8.10.1.11 Importing From Non-Readable File

Importing a hook where the PBS server is unable to open the input file because the file is non-existent, has a permission problem, or any other system-related error causes the following error message to be printed in stderr and in the server logs:

"qmgr: hook error: unable to open <filename> by server run by <user>@<host>: <error message>"

Examples:

"qmgr: hook error: unable to open hook1.py by server run by pbsadmin@hostX: permission denied"

"qmgr: hook error: unable to open hook1.py by server run by pbsadmin@hostY: No such file or directory"

8.10.1.12 Importing or Exporting with Wrong Content Type

Importing or exporting a hook where the <*content-type*> is something other than "*application/x-python*" causes the following error message to be printed in stderr and in the server logs:

"qmgr: hook error: <content_type> must be 'application/x-python'"

Importing/exporting a hook where the <*content-encoding*> is something other than "*default*" or "*base64*" causes the following error message to be printed in stderr and on the server logs:

"qmgr: hook error: <content_encoding> must be 'default' or 'base64'"

An import call on a hook that already has a content script results in the following informational message being printed in stdout and server logs:

"qmgr: hook <hook_name> contents overwritten by file <hook input file>

8.10.1.13 Setting Vnode State to Invalid Value

Setting a vnode's state attribute to an invalid value causes the pbs.BadAttributeValueError exception to be raised.

8.10.1.14 Creating a Hook with Same Name as Existing Hook

You may find that when you remove a hook, it may take some time for the hook to be completely purged. If you run "qmgr -c 'create hook <hook_name>'" where a previous hook of the same <*hook_name*> still exists, you will see the following message:

"hook name <hook_name> is pending delete, try another name"

Either specify another name for the hook, or retry the qmgr request again later, after the previous hook is completely purged.

8.10.2 Errors And Messages During Hook Execution

8.10.2.1 Successful Operation of runjob Hook

When a hook successfully sets an attribute, one of the following is written to the server's log:

<job ID>; '<hook name>' hook set job's <attribute name> = <value>

or

Job held by '<hook name>' hook on <timedate>

8.10.2.2 Unsuccessful Operation for runjob Hook

When a hook fails to set an attribute, the following is written to the server's log:

<job ID>; '<hook name>' hook failed to set job's <attribute name> = <value>

8.10.2.3 Rejecting an Action

If a hook rejects an action by calling the pbs.event().reject() function:

- The following messages are printed to stderr of the command that triggered the hook:

  "<command_name>: Request rejected by filter hook <hook_name>" "<command_name>:<'msg' value passed to pbs.event().reject()>"

  where 'msg' is the message passed (if any) as input to pbs.event().reject().
- The following messages are printed in the appropriate PBS daemon log, logged at event class 0x0400:

  "<user>@<host>…<request type> request rejected by <hook name> "<user>@<host> …<request type> <'msg' value passed to pbs.event().reject()>"

8.10.2.4 Triggering an Alarm

If the alarm was triggered while executing a hook:

- The command that initiated the request gets the following messages in its stderr:
  "<command_name>: Request rejected by filter hook <hook_name>" "<command_name>: alarm call while running hook <hook_name>"
- The following entry appears in the appropriate PBS daemon log, logged under event class PBSEVENT_DEBUG2:
  "<user>@<host>…<request type> alarm call while running hook <hook_name>, request rejected"

8.10.2.5 Encountering an Unhandled Exception

If a hook encounters an unhandled exception:

- PBS rejects the corresponding action. The command that triggered the hook gets the following message in stderr:
  "<command_name>: request rejected as filter hook <hook_name> encountered an exception. Inform admin."
- The following message appears on the appropriate PBS daemon log, logged under PBSEVENT_DEBUG2 event class:
  "<request type> hook <hook_name> encountered an exception, request rejected"

See section 5.2.3, “Hook Alarm Calls and Unhandled Exceptions”, on page 44.

8.10.2.6 Starting and Finishing Hook Execution

Whenever hook execution starts or finishes, timestamped 0x0400 event class log messages appear in the appropriate PBS daemon log:

"11/13/2007 00:00:42 …<user>@<host>…<request type> running hook named <hook name>"

"11/13/2007 00:01:42<user@><host>…<request type> <hook_name> finished"

8.10.2.7 Hook Timeout

When a hook timeout is triggered, the hook script gets a Python KeyboardInterrupt from the PBS server. The server logs show the following:

```
06/17/2008 17:57:16;0001;Server@host2;Svr;Server@host2;PBS server internal error (15011) in
    Python script received a KeyboardInterrupt, <type 'exceptions.KeyboardInterrupt'>
```

8.10.2.8 Hooks Attempting I/O

When the PBS server is running, stdout, stderr, and stdin are closed, so that a hook script containing calls to print to standard output or standard error, or to read input from standard input, gets the following exception:

```
02/24/2008 08:03:34;0086;Server@a-centauri;Svr;Server@a-centauri;Compiling script file:
    </var/spool/pbs/server_priv/hooks/hook_test.PY>
02/24/2008 08:03:34;0001;Server@a-centauri;Svr;Server@a-centauri;PBS server internal error
    (15011) in Error evaluating Python script, <type 'exceptions.IOError'>
```

8.10.2.9 Bad Value for debug Attribute

If you specify an invalid value for a hook's debug attribute, the following error message appears in qmgr's STDERR:

"unexpected value '<bad_val>' must be (not case sensitive) true|t|y|1|false|f|n|0"

8.10.2.10 Commands Fail Inside Hooks

When a command fails inside a hook, but succeeds outside the hook, the problem may be a difference in the environments.

8.10.2.11 runjob Hook Errors

8.10.2.11.i Modifying Hold, Execution Time, Dependency, or Project of Accepted Job

If a runjob hook accepts an event request, using pbs.event().accept(), but attempts to set a disallowed attribute, the hook request is rejected.

If the hook is triggered by a `qrun` command, the following message is sent to `stderr` where the `qrun` command was run. If the hook is triggered when the scheduler tries to run the job, the following message is written to the job's comment attribute:

```
request rejected by filter hook <hook_name>: cannot modify job after runjob request has been
    accepted.
```

The following message is written to the PBS server log, at log event class PBSEVENT_DEBUG2:

```
<hook name>; Found job <attribute name> attribute flagged to be set
runjob request rejected by <hook name>: cannot modify job after runjob request has been accepted.
```

8.10.2.11.ii Modifying Disallowed Attributes of Rejected Job

If a runjob hook rejects an event request, using pbs.event().reject(), but attempts to do any of the above, the following message is written to the PBS server log, at log event class 0x0100:

```
runjob request rejected by <hook name>: cannot modify job attribute
<attribute name> after runjob request has been rejected.
```

8.10.2.11.iii Modifying Vnode

If a runjob hook event is accepted via a pbs.event().accept() call, and yet an attempt is made to modify a vnode's state, then the hook request is rejected. The following message is sent to the `stderr` of `qrun`, and becomes the job's comment:

```
request rejected by filter hook <hook_name>: cannot modify vnode after runjob request has been
    accepted.
```

The following message appears in the PBS server log, logged at event class PBSEVENT_DEBUG2:

```
runjob request rejected by <hook name>: cannot modify a vnode after runjob request has been
    accepted.
```

8.10.2.11.iv runjob Hook Referencing Wrong Parameter

If a runjob hook attempts to reference a pbs.event() parameter other than pbs.event().job, the exception pbs.EventIncompatibleError is raised.

8.10.2.11.v Attempting to Set Restricted Resource

A runjob hook cannot set the value of a Resource_List member other than those listed in Table 5-11, “Built-in Job Resources Readable & Settable by Hooks via Job Events,” on page 64.

Setting any of the wrong resources results in the following:

- The hook request is rejected
- The following message is sent to the STDERR of qrun, or after the failed pbs_runjob():

  " request rejected by filter hook: '<hook name>' hook failed to set job's Resource_List.<resc_name> = <resc_value> (not allowed)"
- The scheduler updates the affected job's comment attribute with the above message.
- The following message appears in the server's log, logged at level PBSEVENT_DEBUG2:

  "runjob request rejected: '<hook name>' hook failed to set job's Resource_list.<resc_name> = <resc_value> (not allowed)"

8.10.2.12 Special Errors Requiring Support

If you encounter any of the following log messages, an internal failure has occurred during hook setup. Please contact PBS Professional support:

```
04/15/2011 17:55:23;0100;Server@jobim;Hook;<hook_name>t3;Encountered an error while setting event
04/15/2011 17:55:23;0001;Server@jobim;Svr;Server@jobim;PBS server internal error (15011) in
    _get_job, partially populated python job object
04/15/2011 17:55:23;0001;Server@jobim;Svr;Server@jobim;PBS server internal error (15011) in
    _get_server, partially populated python server object
04/15/2011 17:55:26;0001;Server@jobim;Svr;Server@jobim;PBS server internal error (15011) in
    _get_queue, partially populated python queue object
04/15/2011 17:55:26;0001;Server@jobim;Svr;Server@jobim;PBS server internal error (15011) in
    _get_vnode, partially populated python vnode object
04/15/2011 17:55:26;0001;Server@jobim;Svr;Server@jobim;PBS server internal error (15011) in
    _get_resv, warning: partially populated python resv object
```

8.10.3 Errors During Startup

If the server starts up and encounters a hook that has no content (no script was imported into the hook), PBS displays the following warning:

```
"failed to stat <path_server_priv_hooks>/<hook_name>.PY"
"failed to allocate storage for python script
<path_server_priv_hooks>/<hook_name>.PY"
```

8.10.4 Errors in Hook Updates

Updates to hooks are asynchronous with respect to jobs. During an update, some jobs may run on updated MoMs while others run on MoMs that are not yet updated. A multi-host job that started running before the update may find itself running on some MoMs that are updated and some that are not. In addition, a multi-host job that starts during the update may start on updated and non-updated MoMs. When a job triggers a hook, the hook that runs is the current hook, not the hook that was there when the job started. If you change, delete, or add a hook while a job is running, and the job subsequently triggers the hook, that job will encounter whatever changes have propagated to the MoM.

- If a job runs where a hook update is incomplete, PBS prints the following to the server's log file:

  "vnode <node_name>'s parent mom <mom_host>:<mom_port> has a pending copy hook or delete hook request"

Bear in mind that hooks are updated asynchronously with respect to jobs, so a multi-host job that started before the update may encounter an incompletely updated hook.

- As PBS copies or deletes execution or periodic hooks to the MoMs, the following messages are printed in the server's log file at 2047:

  "successfully sent hook file <filename> to <mom_hostname>"

  "successfully sent rescdef file <filename> to <mom host name>"

  "successfully deleted hook file <filename> from <mom host name>"

  "successfully deleted rescdef file <filename> from <mom host name>"

  "failed to copy hook file <filename> to <mom host name>"

  "failed to copy rescdef file <filename> to <mom host name>"

  "failed to delete hook file <filename> from <mom host name>"

  "failed to delete rescdef file <filename> from <mom host name>"

- You may find that when you remove a hook, it takes some time for the hook to be completely purged. If you run "`qmgr -c 'create hook <hook_name>'`" where a previous hook of the same <*hook_name*> still exists, you will see the following message:

  "hook name <hook_name> is pending delete, try another name"

  Either specify another name for the hook, or retry the `qmgr` request again later, after the previous hook is completely purged.

- If a hook tries to use a resource that is not yet propagated, this will cause an exception, which if unhandled, may delete the job. Write your hooks so that they trap exceptions and deal gracefully with the job. For example, you can use pbs.event().job.rerun(). Custom resources are propagated to MoMs under the following circumstances:
  - When you install PBS on a multi-vnoded machine
  - When you add MoMs, resources are propagated to those MoMs
  - When you create a custom resource inside a hook

8.10.5 Hook-related Error Codes

The following are hook-related error codes:

Table 8-3: Hook-related Error Codes

Error Name	Code	Description
PBSE_MOM_INCOMPLETE_HOOK	*15167*	Execution hook not fully transferred to a particular MoM
PBSE_MOM_REJECT_ROOT_SCRIPTS	*15168*	A MoM has rejected a request to copy a hook-related file, or a job script to be executed by root
PBSE_HOOK_REJECT	*15169*	A MoM received a reject result from an execution or periodic hook
PBSE_HOOK_REJECT_RERUNJOB	*15170*	Hook rejection requiring a job to be rerun
PBSE_HOOK_REJECT_DELETEJOB	*15171*	Hook rejection requiring a job to be deleted

8.10.6 Troubleshooting

8.10.6.1 Bad Interpreter Path

If you see the following error:

```
/opt/pbs/bin/pbs_python: bad interpreter: No such file or directory
```

You should check to see whether this is a valid path on this host. Try to `cd` to the job execution directory and execute any command using this interpreter path.

8.10.6.2 Viewing Hook Propagation

You don't need to restart `pbs_mom` for a MoM hook to take effect. If you use `qmgr`, PBS takes care of copying the new hook over to the MoM, in the background. It's possible a job may have seen the old MoM hook before the new hook arrives. After the new hook arrives, you'll see a message in the `server_logs` with the following:

```
vnode <name>'s parent mom <mom_name> has a pending copy hook or delete hook request
```

9
Hook Examples

Contents

9.1 queuejob Hook Examples

Example 9-1: Reject jobs which do not specify walltime

Hook type: queuejob

Script RequireWalltime.py:

```
import pbs
import sys

try:
    e = pbs.event()
    j = e.job
    if j.Resource_List["walltime"] == None :
        e.reject("Job has no walltime requested")

except SystemExit:
    pass

except pbs.UnsetResourceNameError:
    e.reject("Job has no walltime requested")
```

Create hook and import script:

```
qmgr -c 'create hook RequireWalltime event="queuejob"'
qmgr -c 'import hook RequireWalltime application/x-python default RequireWalltime.py'
```

Example 9-2: *Reject jobs with CPU requests that are not multiples of 8*

Hook type: queuejob

Script Multiple8.py:

```
import pbs
import sys

e = pbs.event()
j = e.job

mult_limit = 8

if j.Resource_List["ncpus"] != None:
    try:
        e = pbs.event()
        j = e.job
        R = j.Resource_List["ncpus"] % mult_limit
        if R != 0:
            e.reject("Ncpus resource is not a multiple of %s." % (mult_limit,))
    except SystemExit:
        pass
    except (pbs.UnsetResourceNameError, TypeError):
        e.reject("Bad ncpus resource value.")

else:
    R = pbs.event().job.Resource_List
    sel = repr(R["select"])
    tot_ncpus = 0
    for chunk in sel.split("+"):
        nchunks = 1
        for c in chunk.split(":"):
            kv = c.split("=")
            if len(kv) == 1:
                nchunks = kv[0]
            elif len(kv) == 2:
                if kv[0] == "ncpus":
                    tot_ncpus += (int(nchunks) * int(kv[1]))

    try:
        mod = tot_ncpus % mult_limit
        if mod != 0:
            e.reject("Ncpus resource is not a multiple of %s." % \
            (mult_limit,))
    except SystemExit:
        pass
    except (pbs.UnsetResourceNameError, TypeError):
```

```
        e.reject("Bad Ncpus resource value.")
```

Create hook and import script:

```
qmgr -c 'create hook Multiple8 event="queuejob"'
qmgr -c 'import hook Multiple8 application/x-python default Multiple8.py'
```

Example 9-3: *If a user asks for* `-l ncpus=8:ppn=24`*, change* ncpus *to 24*

Hook type: queuejob

Script `ChangeNcpus.py`:

```
import pbs
import sys

try:
    e = pbs.event()
    j = e.job
    j.Resource_List["ncpus"] = max(j.Resource_List["ncpus"],j.Resource_List["ppn"])

except SystemExit:
    pass

except (pbs.UnsetResourceNameError, pbs.BadResourceValError):
    e.reject("Failed to reset ncpus value")
```

Create hook and import script:

```
qmgr -c 'create hook ChangeNcpus event="queuejob"'
qmgr -c 'import hook ChangeNcpus application/x-python default ChangeNcpus.py'
```

Example 9-4: *Calculate and set custom resource*

Hook type: queuejob

Custom resource cph == total ncpus * walltime (in hours). Calculate it and set its value.

You must create the cph resource before using it.

Script CustCPH.py:

```
import pbs

R = pbs.event().job.Resource_List
sel = repr(R["select"])
tot_ncpus = 0
for chunk in sel.split("+"):
    nchunks = 1
    for c in chunk.split(":"):
        kv = c.split("=")
        if len(kv) == 1:
            nchunks = kv[0]
        elif len(kv) == 2:
            if kv[0] == "ncpus":
                tot_ncpus += (int(nchunks) * int(kv[1]))
R["cph"] = tot_ncpus * R["walltime"]
```

Create hook and import script:

```
qmgr -c 'create hook CustCPH event="queuejob"'
qmgr -c 'import hook CustCPH application/x-python default CustCPH.py'
```

Example 9-5: *Put interactive jobs in a particular queue*

Hook type: queuejob

Put job into "interQ" if the job was submitted interactively (using *qsub -I*).

Script IQueue.py:

```
# get the pbs module
import pbs
import sys
try:
    # Get the hook event information and parameters
    # This will be for the 'queuejob' event type.
    e = pbs.event()

    # Get the information for the job being queued
    j = e.job
    if j.interactive:
        # Get the "interQ" queue object
        q = pbs.server().queue("interQ")
        # Reset the job's destination queue
        # parameter for this event
        j.queue = q
        # accept the event
        e.accept()
except SystemExit:
    pass
except:
    e.reject("Failed to route job to queue interQ")
```

Create hook and import script:

```
qmgr -c 'create hook IQueue event="queuejob"'
qmgr -c 'import hook IQueue application/x-python default IQueue.py'
```

Example 9-6: *Set job project based on queue where job is submitted*

Hook type: queuejob

The following is a snippet of a queuejob hook:

```
import pbs
e = pbs.event()
If e.job.queue == None:
    # user did not specify a queue to submit to, so use default
    target_qname = pbs.server().default_queue
else:
    target_qname = e.job.queue.name
If (target_qname == "large") or (target_qname == "medium"):
    e.job.project = "some_large_medium_project"
```

Example 9-7: Speed up throughput of interactive jobs

Hook type: queuejob

Use a queuejob hook that determines whether a job entering the system is an interactive job. If so, it directs the job to the high priority queue specified in 'high_priority_queue', and tells the server to restart the scheduling cycle. You must first define a "high" queue as follows:

```
qmgr -c "create queue high queue_type=e,Priority=150"
qenable high
qstart high
```

The default priority for an express queue is *150*. If you do not want interactive jobs to go into an express queue, set the priority of the queue named "high" to a value greater than ordinary queues but lower than the value for an express queue. See section 4.9.18, “Express Queues”, on page 138.

Instantiate the hook as follows:

```
qmgr -c "create hook rapid_inter event=queuejob"
qmgr -c "import hook rapid_inter application/x-python default rapid_inter.py"
```

Hook script:

```
import pbs

high_priority_queue="high"

e = pbs.event()
if e.job.interactive:
    high = pbs.server().queue(high_priority_queue)
    if high != None:
        e.job.queue = high
        pbs.logmsg(pbs.LOG_DEBUG, "quick start interactive job")
        pbs.server().scheduler_restart_cycle()
```

Example 9-8: Validate job account

This hook reads valid accounts from a JSON file.

```
import os
import simplejson

try:
    import pbs

    pbs_conf = pbs.pbs_conf

except ImportError:
    pass

# Read in the configurations file
pbs_hook_cfg = pbs.hook_config_filename
if pbs_hook_cfg == None:
    pbs.logmsg(pbs.EVENT_DEBUG3,"%s"%os.environ)
    pbs_hook_cfg = os.environ["PBS_HOOK_CONFIG_FILE"]
pbs.logmsg(pbs.EVENT_DEBUG3,"read config file: %s"%pbs.hook_config_filename)
config_file = open(pbs.hook_config_filename).read()

va_cfg = simplejson.loads(config_file)

#pbs.logmsg(pbs.EVENT_DEBUG2,"config file: %s"%va_cfg)

je = pbs.event()
j = pbs.event().job

user=je.requestor

account=j.Account_Name

#pbs.logmsg(pbs.EVENT_DEBUG2,"my Account_Name is: %s"%account)
#pbs.logmsg(pbs.EVENT_DEBUG2,"allowed users for this account are:
    %s"%va_cfg["accounts"][account])

if user in va_cfg["accounts"][account]:
    pbs.logmsg(pbs.EVENT_DEBUG2,"user is allowed to submit to account")
else:
    pbs.logmsg(pbs.EVENT_DEBUG2,"user is NOT allowed to submit to account")
    je.reject("user is unauthorized to submit to this account")
```

Here is an example JSON file with valid accounts:

```
{
   "accounts": {
      "account1":["user1"],
      "account11":["user11"],
      "account2":["user2"],
      "accountall":["user1","user2"]
   }
}
```

Example 9-9: *Check job resource request and verify that job can run in this complex*

```
#!/usr/bin/env python

# -*- coding: utf-8 -*-

# Purpose: To check the request of the job and verify that it will be able to
#         run on this cluster
#
# Setup: Modify the config file. You will need to provide the correct
#   information for your complex

import pbs
import sys
import os
from string import join
import simplejson as json
import traceback
import re
import string

pbs.logmsg(pbs.EVENT_DEBUG, "Entering the check limits hook")
e = pbs.event()

#
# FUNCTION convert_size
#
# Convert a string containing a size specification (e.g. "1m") to a
# string using different units (e.g. "1024k").
#
# This function only interprets a decimal number at the start of the string,
# stopping at any unrecognized character and ignoring the rest of the string.
#
# When down-converting (e.g. MB to KB), all calculations involve integers and
# the result returned is exact. When up-converting (e.g. KB to MB) floating
# point numbers are involved. The result is rounded up. For example:
#
```

```
# 1023MB -> GB yields 1g
# 1024MB -> GB yields 1g
# 1025MB -> GB yields 2g  <-- This value was rounded up
#
# Pattern matching or conversion may result in exceptions.
#

```

9.2 modifyjob Hook Examples

Example 9-10: Prevent users from using *qalter* to change their jobs

Hook type: modifyjob

Allow only administrators to change jobs.

Script NoAlter.py, on Windows, in a domain:

```
import os
import pbs

e = pbs.event()
j = e.job
who = e.requestor
pbs.logmsg(pbs.LOG_DEBUG, "requestor=%s" % (who,))
isadmin=0
admin_ulist = ["PBS_Server", "Scheduler", "pbs_mom", "Administrator"]

if who in admin_ulist:
    isadmin=1
else:
    cmd = "net user "  + who + " /domain"
    admin_glist = ['Administrators', 'Domain Admins', 'Enterprise
        Admins']
    for line in os.popen(cmd).readlines():
        if line.find("Group") >= 0:
            for li in line.split("*"):
                if li.strip() in admin_glist:
                    isadmin=1
                    break
if e.type == pbs.HOOK_EVENT_MODIFYJOB and not isadmin:
    e.reject("Normal users are not allowed to modify their jobs")
```

Script NoAlter.py, on Linux:

```
import pbs
e = pbs.event()
j = e.job
who = e.requestor
pbs.logmsg(pbs.LOG_DEBUG, "requestor=%s" % (who,))
admin_ulist = ["PBS_Server", "Scheduler", "pbs_mom", "root"]
if who not in admin_ulist:
    e.reject("Normal users are not allowed to modify their jobs")
```

Create hook and import script:

```
qmgr -c 'create hook NoAlter event="modifyjob"'
qmgr -c 'import hook NoAlter application/x-python default NoAlter.py'
```

Example 9-11: *Reject jobs requesting a specific queue that do not request mem*

Hook type: modifyjob

Reject jobs requesting workq2 if they don't also request memory.

Script queuespec.py:

```
import pbs
import sys
try:
    e = pbs.event()
    j = e.job
    if j.queue.name == "workq2" and not j.Resource_List["mem"]:
        e.reject("workq2 requires job to have mem specification")

except SystemExit:
    pass

except:
    e.reject("%s hook failed with %s. Please contact
        Admin" % (e.hook_name, sys.exc_info()[:2]))
```

Create hook, import script:

```
qmgr -c 'create hook queuespec event="modifyjob"'
qmgr -c 'import hook queuespec application/x-python default queuespec.py'
```

9.3 jobobit Hook Examples

Example 9-12: jobobit hook

```
import pbs
import sys
try:
    e = pbs.event()
    job = e.job
    pbs.logjobmsg(job.id, 'jobobit hook, "%s" started' % (e.hook_name,))
    pbs.logjobmsg(job.id, 'jobobit hook, job starttime:%s' % (job.stime,))
    pbs.logjobmsg(job.id, 'jobobit hook, job obittime:%s' % (job.obittime,))
    pbs.logjobmsg(job.id, 'jobobit hook, job_state=%s' % (job.job_state,))
    pbs.logjobmsg(job.id, 'jobobit hook, job_substate=%s' % (job.substate,))
    state_desc = pbs.REVERSE_JOB_STATE.get(job.job_state, '(None)')
    substate_desc = pbs.REVERSE_JOB_SUBSTATE.get(job.substate, '(None)')
    pbs.logjobmsg(job.id, 'jobobit hook, job_state_desc=%s' % (state_desc,))
    pbs.logjobmsg(job.id, 'jobobit hook, job_substate_desc=%s' % (substate_desc,))
    if hasattr(job, "resv") and job.resv:
        pbs.logjobmsg(job.id, 'jobobit hook, resv:%s' % (job.resv.resvid,))
        pbs.logjobmsg(job.id, 'jobobit hook, resv_nodes:%s' % (job.resv.resv_nodes,))
        pbs.logjobmsg(job.id, 'jobobit hook, resv_state:%s' % (job.resv.reserve_state,))
    else:
        pbs.logjobmsg(job.id, 'jobobit hook, resv:(None)')
    pbs.logjobmsg(job.id, 'jobobit hook, "%s" finished' % (e.hook_name,))
except Exception as err:
    ty, _, tb = sys.exc_info()
    pbs.logmsg(pbs.LOG_ERROR, "jobobit hook, error: " + str(ty) +
        str(tb.tb_frame.f_code.co_filename) + str(tb.tb_lineno))
    e.reject()
else:
    e.accept()
```

PBS server log excerpt of a jobobit hook executing:

```
10/11/2021 19:57:16.179481;0008;Server@pdw-s1;Job;7.pdw-s1;jobobit hook, "jobobit_example"

    finished
```

9.4 execjob_launch Hook Examples

Example 9-13: Modify arguments to job program

Hook type: execjob_launch

The argv[] entries can be modified to change the existing arguments to progname.

Given the following hook:

```
# cat launch.py
import pbs
e = pbs.event()
e.argv[1] = "cool"

# qmgr -c "create hook launch event=execjob_launch"
# qmgr -c "import hook launch application/x-python default launch.py"
```

So if a job is submitted as follows:

```
% qsub -- /bin/echo uncool
```

When the job is submitted, progname = "/*bin*/*echo*", argv[0] = "/*bin*/*echo*", argv[1]="*uncool*". However, when the job executes, the execjob_launch hook runs, causing "/bin/echo cool" to execute instead of "/bin/echo uncool".

9.5 execjob_prologue and execjob_epilogue Hook Examples

Example 9-14: Run shell script prologue or epilogue.

You can use this hook when the execjob_prologue and execjob_epilogue events are used in other hooks, such as the cgroups hook, and you still want to run the classic prologue and epilogue scripts we describe in section "Using Shell Scripts for Prologue and Epilogue", on page 458 in the PBS Professional Administrator's Guide. Additionally, the hook introduces parallel prologue and epilogue shell scripts.

See "Using Hooks for Prologue and Epilogue", on page 462 in the PBS Professional Administrator's Guide, for configuration and installation instructions.

This hook is included in $PBS_EXEC/unsupported. as run_pelog_shell.py, along with its configuration file, run_pelog_shell.ini.

Configuration File

Here is the contents of run_pelog_shell.ini:

```
[run_pelog_shell]
# Enable parallel prologues/epilogues that run on sister moms. Note that all
# the normal requirements apply, except the scripts should be named pprologue
# and pepilogue.
ENABLE_PARALLEL=False

# Provide verbose hook output to the user's .o/.e file
VERBOSE_USER_OUTPUT=False

# DEFAULT_ACTION can be one of DELETE or RERUN
DEFAULT_ACTION=RERUN

# Enable Torque argument compatibility
TORQUE_COMPAT=False
```

Hook Script

Here is the hook script (the contents of run_pelog_shell.py):

```
import pbs
import os, sys
import time

# Set up a few variables
start_time=time.time()
pbs_event=pbs.event()
hook_name=pbs_event.hook_name
hook_alarm=30 # default, we'll read it from the .HK later
DEBUG=False # default, we'll read it from the .HK later
job=pbs_event.job

# The trace_hook function has been written to be portable between hooks.
def trace_hook(**kwargs):
    """Simple exception trace logger for PBS hooks
    loglevel=<int> (pbs.LOG_DEBUG): log level to pass to pbs.logmsg()
    reject=True: reject the job upon completion of logging trace
    trace_in_reject=<bool> (False): pass trace to pbs.event().reject()
    trace_in_reject=<str>: message to pass to pbs.event().reject() with trace
    Usage:
    try:
        your=code(here)
    except:
        trace_hook()
    """
    import sys

    if 'loglevel' in kwargs:
        loglevel=kwargs['loglevel']
    else:
        loglevel=pbs.LOG_ERROR
    if 'reject' in kwargs:
        reject=kwargs['reject']
    else:
        reject=True
    if 'trace_in_reject' in kwargs:
        trace_in_reject=kwargs['trace_in_reject']
    else:
        trace_in_reject=False

    # Associate hook events with the appropriate PBS constant. This is a list

    resources_available.host = mars
    resources_available.ncpus = 7 (set in hook)
    resources_available.vnode = mars[1]
```

9.7 exechost_periodic Hook Examples

Example 9-16: Monitor load; offline or free vnode depending on CPU load

Hook type: exechost_periodic

Monitor load average on the local host. Offline or free the vnode representing the host depending on the CPU load.

You can modify values for ideal_load and max_load. Your hook does the following:

If the system's CPU load average rises above max_load, the state of the vnode corresponding to the current host is set to *offline*. This prevents the scheduler from scheduling jobs on this vnode.

If the system's CPU load average falls below ideal_load, the state of the vnode representing the current host is set to *free*. This allows the scheduler to schedule jobs on this vnode.

To instantiate this hook, specify the following:

```
qmgr -c "create hook load_balance event=exechost_periodic,freq=10"
qmgr -c "import hook load_balance application/x-python default load_balance.py"
```

Hook script:

```
import pbs
import os
import re

ideal_load=1.5
max_load=2.0

# get_la: returns a list of load averages within the past 1-minute, 5-minute, 15-minutes range.
def get_la():
    line=os.popen("uptime").read()
    r = re.search(r'load average: (\S+), (\S+), (\S+)$', line).groups()
    return map(float, r)

local_node = pbs.get_local_nodename()

vnl = pbs.event().vnode_list
current_state = pbs.server().vnode(local_node).state
mla = get_la()[0]
if (mla >= max_load) and ((current_state == pbs.ND_OFFLINE) == 0):
    vnl[local_node].state = pbs.ND_OFFLINE
    vnl[local_node].comment = "offlined node as it is heavily loaded"
elif (mla < ideal_load) and ((current_state == pbs.ND_OFFLINE) != 0):
    vnl[local_node].state = pbs.ND_FREE
    vnl[local_node].comment = None
```

Example 9-17: Periodically update resources on vnodes

Hook type: exechost_periodic

Periodically update the values of a set of custom resources for the vnode where the current MoM runs.

The current set includes two size types, which are scratch and home

Prerequisites:

1. Create the following custom resources:

```
qmgr -c "create resource scratch type=size, flag=nh"
qmgr -c "create resource home type=size, flag=nh"
```

2. Add the new resources to the "resources:" line in the sched_config file and restart pbs_sched:

```
% cat PBS_HOME/sched_priv/sched_config resources
ncpus, mem, arch, [...], scratch, home
```

3. Install this hook as follows:

```
qmgr -c "create hook mom_dyn_res event=exechost_periodic,freq=30"
qmgr -c "import hook mom_dyn_res application/x-python default mom_dyn_res.py"
```

The mom_dyn_res.py script:

```
# NOTE:
#  Update the dyn_res[] array below to include any other custom resources
#  to be included in the updates. Ensure that each resource added has an
#  entry in the scheduler's sched_config file.

import pbs
import os
import sys

# get_filesystem_avail_unprivileged: returns available size in kbytes
# (in pbs.size type) to unprivileged users, of the filesystem where
# 'dirname' resides.

def get_filesystem_avail_unprivileged( dirname ):
    o = os.statvfs(dirname)
    return pbs.size( "%skb" % ((o.f_bsize * o.f_bavail) / 1024) )

# get_filesystem_avail_privileged: returns available size in kbytes
# (in pbs.size type) to privileged users, of the filesystem where 'dirname'
# resides.

def get_filesystem_avail_privileged( dirname ):
    o = os.statvfs(dirname)
    return pbs.size( "%skb" % ((o.f_bsize * o.f_bfree) / 1024) )

try:
    # Define here the custom resources as key, and the function and its
    # argument for obtaining the value of the custom resource:
```

```
    #   Format: dyn_res[<resource_name>] = [<function_name>,
    #                   <function_argument>]
    # So "<function_name>(<function_argument>)" is called to return the
    # value for custom <resource_name>.
    dyn_res = {}
    dyn_res["scratch"] = [get_filesystem_avail_unprivileged, "/tmp"]
    dyn_res["home"]= [get_filesystem_avail_unprivileged, "/home"]

    vnl = pbs.event().vnode_list
    local_node = pbs.get_local_nodename()

    for k in dyn_res.keys():
        vnl[local_node].resources_available[k] = dyn_res[k][0](dyn_res[k][1])

except SystemExit:
    pass

except:
    e = pbs.event()
    e.reject("%s hook failed with %s. Please contact Admin" % \
    (e.hook_name, sys.exc_info()[:2]))
```

Example 9-18: Log loads on vnodes

Hook type: exechost_periodic

You must create the custom resources r1m, r5m, and r15m on the vnodes.

```
#cat getload.py

import pbs
import sys
import os
load = os.getloadavg()
r1m = load[0]
r5m = load[1]
r15m = load[2]
e = pbs.event()
mynode = pbs.get_local_nodename()
v = e.vnode_list[mynode]
v.resources_available["r1m"] = r1m
v.resources_available["r5m"] = r5m
v.resources_available["r15m"] = r15m
pbs.logmsg(pbs.LOG_DEBUG,"getloadavg: vnode %s, r1m = %f, r5m = %f, r15m = %f" %
(repr(mynode), r1m, r5m, r15m))
```

Example 9-19: *Set job attributes and resources*

Hook type: exechost_periodic

```
% cat period.py
import pbs
E = pbs.event()
for k in e.job_list.keys():
    e.job_list[k].resources_used["mem"] = pbs.size("7gb")
    e.job_list[k].Variable_List["POLI"] = "negri"
    e.job_list[k].Hold_Types = pbs.hold_types("us")
```

Create the hook:

```
# qmgr -c "create hook period event=exechost_periodic,freq=30"
# qmgr -c "import hook period application/x-python default period.py"
```

Submit several jobs:

```
% qsub job.scr
<job-id1>
% qsub job.scr
<job-id2>
```

As the exechost_periodic hook executes, the jobs get the new values:

```
% qstat -f <job-id1>
…
Resources_used.mem = 7gb
Hold_Types = us
Variable_List = …POLI=negri…
2
% qstat -f <job-id1>
…
Resources_used.mem = 7gb
Hold_Types = us
Variable_List = …POLI=negri…
```

9.8 resvsub Hook Examples

Example 9-20: Restrict ability to submit reservations to PBS administrators

Hook type: resvsub

Script NoSub.py on Windows:

```
import pbs
import os
e = pbs.event()
r = e.resv
who = e.requestor
pbs.logmsg(pbs.LOG_DEBUG, "requestor=%s" % (who,))
isadmin=0

admin_ulist = ["PBS_Server", "Scheduler", "pbs_mom", "Administrator"]
if who in admin_ulist:
    isadmin=1
else:
    cmd = "net user "  + who + "/domain"
    admin_glist = ['Administrators', 'Domain Admins', 'Enterprise
        Admins']
    for line in os.popen(cmd).readlines():
        if line.find("Group") >= 0:
            for li in line.split("*"):
                if li.strip() in admin_glist:
                    isadmin=1
                    break
if e.type == pbs.HOOK_EVENT_RESVSUB and not isadmin:
    e.reject("Only admins allowed to create reservations!")
```

Script NoSub.py on Linux:

```
import pbs
import os
e = pbs.event()
r = e.resv
who = e.requestor
pbs.logmsg(pbs.LOG_DEBUG, "requestor=%s" % (who,))

admin_ulist = ["PBS_Server", "Scheduler", "pbs_mom", "root"]

if e.type == pbs.HOOK_EVENT_RESVSUB and who not in admin_ulist:
    e.reject("Only admins allowed to create reservations!")
```

Create hook and import script:

```
qmgr -c 'create hook NoSub event="resvsub"'
qmgr -c 'import hook NoSub application/x-python default NoSub.py'
```

9.9 periodic Hook Examples

Example 9-21: Run job start time estimator

Hook type: periodic

Run job start time estimator named pbs_est.

Script run_pbs_est.py:

```
import pbs
import time
import os
import subprocess

pbs_est_cmd = os.path.join(pbs.pbs_conf['PBS_EXEC'], 'sbin', 'pbs_est')

e = pbs.event()

pbs.logmsg(pbs.LOG_DEBUG, "Starting job start time estimation task")

exit_stat = subprocess.call([pbs_est_cmd], shell=True)
if exit_stat != 0:
    e.reject("%s exited abnormally with return code %d" % (pbs_est_cmd, exit_stat))
else:
    e.accept()
```

9.10 modifyvnode Hook Example

Example 9-22: Hook that records current and previous vnode values in the PBS log, for the case where the vnode just went down:

```
# VnodeDownReport draft 20201102 19:46
# Sample modifyvnode event hook script
import pbs
import os, sys

try:
    e = pbs.event()
    vnode = e.vnode # Represents the current (recently changed) state
    vnode_o = e.vnode_o  # Represents the state prior to the change

    if ((int(vnode.state)) & pbs.ND_STATE_VNODE_UNAVAILABLE) and not ((int(vnode_o.state)) &
    pbs.ND_STATE_VNODE_UNAVAILABLE):
        #
        # A node just went down. Report current and previous vnode values.
        #
        # Reports attributes in "Table 5-7: Vnode Attributes" from the 2020.1 Hooks Guide,
        # EXCEPT:
        #   arch (vnode attribute not defined in demo deployment)
        #   hpcbp_enable (vnode attribute not defined in demo deployment)
        #   hpbcbp_stage_protocol (vnode attribute not defined in demo deployment)
        #   hpcbp_webservice_address (vnode attribute not defined in demo deployment)
        #   hhpcbp_user_name (vnode attribute not defined in demo deployment)
        #   topology_info (due to output size)
        #

        # Demonstrate the new vnode state list functions
        vnode_state_str_list = ",".join(vnode.extract_state_strs())
        vnode_o_state_str_list = ",".join(vnode_o.extract_state_strs())
        vnode_state_int_list = ','.join([str(_) for _ in vnode.extract_state_ints()])
        vnode_o_state_int_list = ','.join([str(_) for _ in vnode_o.extract_state_ints()])

        # First print the state values
        pbs.logmsg(pbs.LOG_DEBUG, '%s;%s;state: vnode=%s vnode_o=%s' % \
            (e.hook_name, vnode.name, hex(vnode.state), hex(vnode_o.state)))
        pbs.logmsg(pbs.LOG_DEBUG, '%s;%s;state string list: vnode=%s vnode_o=%s' % \
            (e.hook_name, vnode.name, vnode_state_str_list, vnode_o_state_str_list))
        pbs.logmsg(pbs.LOG_DEBUG, '%s;%s;state int list: vnode=%s vnode_o=%s' % \
            (e.hook_name, vnode.name, vnode_state_int_list, vnode_o_state_int_list))

        # Next print the remaining vnode members
        pbs.logmsg(pbs.LOG_DEBUG, '%s;%s;comment: vnode=%s vnode_o=%s' % \
            (e.hook_name, vnode.name, vnode.comment, vnode_o.comment))
```

```
            pbs.logmsg(pbs.LOG_DEBUG, '%s;%s;current_aoe: vnode=%s vnode_o=%s' % \
                (e.hook_name, vnode.name, vnode.current_aoe, vnode_o.current_aoe))
            pbs.logmsg(pbs.LOG_DEBUG, '%s;%s;in_multivnode_host: vnode=%s vnode_o=%s' % \
                (e.hook_name, vnode.name, vnode.in_multivnode_host, vnode_o.in_multivnode_host))
            pbs.logmsg(pbs.LOG_DEBUG, '%s;%s;jobs: vnode=%s vnode_o=%s' % \
                (e.hook_name, vnode.name, vnode.jobs, vnode_o.jobs))
            pbs.logmsg(pbs.LOG_DEBUG, '%s;%s;last_state_change_time: vnode=%s vnode_o=%s' % \
                (e.hook_name, vnode.name, str(vnode.last_state_change_time),
        str(vnode_o.last_state_change_time)))
            pbs.logmsg(pbs.LOG_DEBUG, '%s;%s;Mom: vnode=%s vnode_o=%s' % \
                (e.hook_name, vnode.name, vnode.Mom, vnode_o.Mom))
            pbs.logmsg(pbs.LOG_DEBUG, '%s;%s;ntype: vnode=%s vnode_o=%s' % \
                (e.hook_name, vnode.name, hex(vnode.ntype), hex(vnode_o.ntype)))

9.11 Multi-event Hooks

Example 9-23: Helper function for logging exceptions more completely and flexibly:

```
# The trace_hook function has been written to be portable between hooks.
def trace_hook(**kwargs):
    """Simple exception trace logger for PBS hooks
    loglevel=<int> (pbs.LOG_DEBUG): log level to pass to pbs.logmsg()
    reject=True: reject the job upon completion of logging trace
    trace_in_reject=<bool> (False): pass trace to pbs.event().reject()
    trace_in_reject=<str>: message to pass to pbs.event().reject() with trace
    Usage:
    try:
        your=code(here)
    except:
        trace_hook()
    """

    import pbs
    import sys

    if 'loglevel' in kwargs:
        loglevel=kwargs['loglevel']
    else:
        loglevel=pbs.LOG_ERROR
    if 'reject' in kwargs:
        reject=kwargs['reject']
    else:
        reject=True
    if 'trace_in_reject' in kwargs:
        trace_in_reject=kwargs['trace_in_reject']
    else:
        trace_in_reject=False

    # Associate hook events with the appropriate PBS constant. This is a list
    # of all hook events as of PBS Pro 13.0. If the event does not exist, it is
    # removed from the list.
    hook_events=['queuejob', 'modifyjob', 'movejob', 'runjob', 'execjob_begin',
                 'execjob_prologue', 'execjob_launch', 'execjob_attach',
                 'execjob_preterm', 'execjob_epilogue', 'execjob_end',
                 'resvsub', 'provision', 'exechost_periodic',
                 'exechost_startup']

    hook_event={}
    for he in hook_events:
        # Only set available hooks for the current version of PBS.
```

```
    if hasattr(pbs, he.upper()):
        event_code=eval('pbs.'+he.upper())
        hook_event[event_code]=he
        hook_event[he]=event_code
        hook_event[he.upper()]=event_code
        del event_code
    else:
        del hook_events[hook_events.index(he)]

Contents

1
Glossary of Terms

This chapter describes the terms used in PBS Professional documentation.

Accept an action (Hooks)

A hook *accepts* an action when the hook allows the action to take place.

Access control list, ACL

An *ACL*, or *Access Control List*, is a list of users, groups, or hosts from which users or groups may be attempting to gain access. This list defines who or what is allowed or denied access to parts of PBS such as the server, queues, or reservations. A server ACL applies to access to the server, and therefore all of PBS. A queue's ACL applies only to that particular queue. A reservation's ACL applies only to that particular reservation. See "ACLs" on page 493 in the PBS Professional Administrator's Guide.

Access to a queue

Applies to users, groups, and hosts. Being able to submit jobs to the queue, move jobs into the queue, being able to perform operations on jobs in the queue, and being able to get the status of the queue.

Access to a reservation

Applies to users, groups, and hosts. Being able to place jobs in the reservation, whether by submitting jobs to the reservation or moving jobs into the reservation. It also means being able to delete the reservation, and being able to operate on the jobs in the reservation.

Access to the server

Applies to users, groups, and hosts. Being able to run PBS commands to submit jobs and perform operations on them such as altering, selecting, and querying status. It also means being able to get the status of the server and queues.

Account string

An *account string* is an arbitrary character string of characters that your site may use to provide additional accounting or charge information. The syntax is unspecified except that it must be a single string. When provided on the command line to a PBS utility or in a directive in a PBS job script, any embedded white space must be escaped by enclosing the string in quotes.

Action (Hooks)

A PBS operation or state transition. The actions that hooks can affect are submitting a job, altering a job, running a job, making a reservation, and moving a job to another queue.

Active (Failover)

A server daemon is active when it is managing user requests and communicating with a scheduler and MoMs.

Active Directory (Windows)

Active Directory is an implementation of LDAP directory services by Microsoft to use in Windows environments. It is a directory service used to store information about the network resources (e.g. user accounts and groups) across a domain.

Admin (Windows)

A user logged in from an account that is either:

1. A member of a group having full control over the local computer and the domain controller
2. Allowed to make domain and schema changes to the Active Directory.

Administrator

Same as PBS Administrator.

Linux: person with Manager privilege and root access.

Windows: person with Manager privilege who is a member of the local Administrators group.

A person who administers PBS, performing functions such as downloading, installing, upgrading, configuring, or managing PBS.

Administrator is distinguished from "site administrator", although often these are the same person.

Administrators (Windows)

A group that has built-in capabilities that give its members full control over the local system, or the domain controller host itself.

Advance reservation

A reservation for a specific set of resources for a specified start time and duration in the future. Advance reservations are created by users to reserve resources for jobs. The reservation is available only to the creator of the reservation and any users or groups specified by the creator.

ALM license server

The license server that supplies licenses to run a PBS complex. See the *PBS Works Licensing Guide*.

AOE, Application operating environment

The environment on a vnode. This may be one that results from provisioning that vnode, or one that is already in place

API

PBS provides an *Application Programming Interface,* or *API,* which is used by the commands to communicate with the server. This API is described in the *PBS Professional Programmer's Guide*. A site may make use of the API to implement new commands if so desired.

Application checkpoint

The application performs its own checkpointing when it receives the appropriate signal etc.

Array job

See "Job array".

ASAP reservation, job-specific ASAP reservation

Reservation created for a specific queued job, for the same resources the job requests. PBS schedules the reservation to run as soon as possible, and PBS moves the job into the reservation. Created when you use `pbs_rsub -Wqmove=<job ID>` on a queued job.

Attribute

An *attribute* is a data item belonging to an object such as a job, reservation, vnode, queue, hook, scheduler, or server. The attribute's value affects the behavior of or provides information about the object. See Chapter 6, "Attributes", on page 277. You specify attributes via the `qmgr` command.

Backfilling

A scheduling policy where

1. High-priority jobs are scheduled for execution
2. Lower-priority jobs are run if the following conditions are true:

   Resources (that cannot be used by the high-priority jobs) are available

   The lower-priority jobs will not delay the higher-priority jobs

Lower-priority jobs selected for execution are those next in priority order that will fit in the available resources.

Batch, Batch processing

Allowing jobs to be run outside of the interactive login environment.

Borrowing vnode

The vnode where a shared vnode resource is available, but not managed.

Built-in hook

A hook that is supplied as part of PBS. These hooks cannot be created or deleted by administrators. See "Managing Built-in Hooks" on page 179 in the PBS Professional Hooks Guide.

Built-in resource

A resource that is defined in PBS Professional as shipped. Examples of built-in resources are ncpus, which tracks the number of CPUs, and mem, which tracks memory. See "Built-in vs. Custom Resources" on page 231 in the PBS Professional Administrator's Guide.

Checkpoint/Restart

Allows jobs to be checkpointed and restarted. Uses OS-provided or third-party checkpoint/restart facility.

Checkpoint and Abort, checkpoint_abort

The checkpoint script or tool writes a restart file, then PBS kills and requeues the job. The job resumes from the start file when it is executed again.

Child vnode

On a multi-vnode machine, there is one parent vnode and one or more child vnodes. For multi-vnode machines, child vnodes represent hardware. See "Parent vnode" on page 13.

Chunk

A set of resources allocated as a unit to a job. Specified inside a selection directive. All parts of a chunk come from the same host. In a typical MPI (Message-Passing Interface) job, there is one chunk per MPI process. See "Chunk Resources" on page 233 in the PBS Professional Administrator's Guide or "Requesting Resources in Chunks", on page 55 of the PBS Professional User's Guide.

Chunk-level resource, host-level resource

A resource that is available at the host level, for example, CPUs or memory. Chunk resources are requested inside of a selection statement. The resources of a chunk are to be applied to the portion of the job running in that chunk.

Chunk resources are requested inside a select statement. A single chunk is requested using this form:

-l select=<resource name>=<value>:<resource name>=<value>

For example, one chunk might have 2 CPUs and 4GB of memory:

```
-l select=ncpus=2:mem=4gb
```

To request multiples of a chunk, prefix the chunk specification by the number of chunks:

-l select=[number of chunks]<chunk specification>

For example, to request six of the previous chunk:

```
-l select=6:ncpus=2:mem=4gb
```

To request different chunks, concatenate the chunks using the plus sign ("+"):

-l select=[number of chunks]<chunk specification>+[number of chunks]<chunk specification>

For example, to request two kinds of chunks, one with 2 CPUs per chunk, and one with 8 CPUs per chunk, both kinds with 4GB of memory:

```
-l select=6:ncpus=2:mem=4gb+3:ncpus=8:mem=4GB
```

Chunk set

An identical set of chunks requested in a select statement. The following is a chunk set: 4:ncpus=8:mem=4GB

Cluster

A relatively homogeneous set of systems that are used as if they are a single machine.

Commands

PBS supplies both command line programs that are POSIX 1003.2d conforming and a graphical interface. These are used to submit, monitor, modify, and delete jobs. These client commands can be installed on any system type supported by PBS and do not require the local presence of any of the other components of PBS.

There are three classifications of commands: user commands (which any authorized user can use), Operator commands, and Manager (or administrator) commands. Operator and Manager commands require specific access privileges.

Communication daemon, comm

The daemon which handles communication between the server, scheduler, and MoMs. Executable is `pbs_comm`.

Complex

A PBS complex consists of the machines running one primary server+scheduler (plus, optionally, a secondary backup server+scheduler) and all the machines on which the MoMs (attached to this server+scheduler) are running. A complex can be a heterogeneous mix of system architectures, and can include one or more clusters.

Consumable resource

A consumable resource is a resource that is reduced or taken up by being used. Examples of consumable resources are memory or CPUs. See "Consumable vs. Non-consumable Resources" on page 231 in the PBS Professional Administrator's Guide.

CPU

Has two meanings, one from a hardware viewpoint, and one from a software viewpoint:

1. A core. The part of a processor that carries out computational tasks. Some systems present virtual cores, for example in hyperthreading.
2. Resource required to execute a program thread. PBS schedules jobs according, in part, to the number of threads, giving each thread a core on which to execute. The resource used by PBS to track CPUs is called "*ncpus*". The number of CPUs available for use defaults to the number of cores reported by the OS. When a job requests one CPU, it is requesting one core on which to run.

Creating a hook

When you "create a hook" using `qmgr`, you're telling PBS that you want it to make you an empty hook object that has no characteristics other than a name.

Custom resource

A resource that is not defined in PBS as shipped. Custom resources are created by the PBS administrator or by PBS for some systems. See "Built-in vs. Custom Resources" on page 231 in the PBS Professional Administrator's Guide.

Data service account

Created by PBS on installation. Account that is internal to the data service, with its own data service password. Used by PBS to log into and do operations on the data service. PBS maps this account to the PBS data service management account. Must have same name as PBS data service management account.

Data service management account

Created by administrator. Account with a system password. Data service account maps to the PBS data service management account and both must have the same name.

Default server

The default server is the server which handles any server tasks, such as client requests, unless you specify a different server. By default, PBS provides a default server; you do not need to take any action to have a default server. If you have installed more than one server, you can specify the default using these:

- The PBS_DEFAULT environment variable
- The PBS_SERVER parameter in `/etc/pbs.conf` on the local host

If both are present, PBS_DEFAULT overrides PBS_SERVER.

Server names have the following format:

<hostname>[:<port number>]

where *hostname* is the fully-qualified domain name of the host on which the server is running and *port number* is the port number to which to connect. If you do not specify *port number*, PBS defaults to using 15001.

There is always at least one active server; the default server is the active server unless another server has been made active.

Degraded reservation

An advance reservation for which one or more associated vnodes are unavailable.

A standing reservation for which one or more vnodes associated with any occurrence are unavailable.

Delegation (Windows)

A capability provided by Active Directory that allows granular assignment of privileges to a domain account or group. So for instance, instead of adding an account to the "Account Operators" group which might give too much access, delegation allows giving the account read access only to all domain users and groups information. This is done via the Delegation wizard.

Deprecate

We use *deprecated* to mean that something such as a feature or a platform is still supported, but will not be supported beginning with a later release. When a feature is no longer supported, we say it has been removed or is obsolete.

Destination, destination identifier, destination queue, destination server

String. One or more queues or a server. Jobs may be queried at or sent to a destination queue. Commands may be directed to a destination queue or server. A destination may be at the default PBS server or at another server.

Destination queue format:

<queue name>

Indicates specified queue at default server.

@<server name>

When moving a job, indicates default queue at that server.

When operating on queues, can indicate all queues at that server.

<queue name>@<server name>

Indicates specified queue at specified server.

Destination server format:

(no server name)

Indicates default server.

@<server name>

Indicates specified server.

@default

Indicates default server.

Directive

A means by which the user specifies to PBS the value of a job submission variable such as number of CPUs, the name of the job, etc. The default start of a directive is "*#PBS*". PBS directives either specify resource requirements or attribute values. See page "Using PBS Directives", on page 17 of the PBS Professional User's Guide.

Domain Admin Account (Windows)

A domain account on Windows that is a member of the "Domain Admins" group.

Domain Admins (Windows)

A global group whose members are authorized to administer the domain. By default, the Domain Admins group is a member of the Administrators group on all computers that have joined a domain, including the domain controllers.

Domain User Account (Windows)

A domain account on Windows that is a member of the Domain Users group.

Domain Users (Windows)

A global group that, by default, includes all user accounts in a domain. When you create a user account in a domain, it is added to this group automatically.

Endpoint

A PBS server, scheduler, or MoM daemon.

Enterprise Admins (Windows)

A group that exists only in the root domain of an Active Directory forest of domains. The group is authorized to make forest-wide changes in Active Directory, such as adding child domains.

Entity, PBS entity

A user, group, or host.

Entity share

Setting job execution and/or preemption priority according to how much of the fairshare tree is assigned to each job's owner.

Event

A PBS operation or state transition. Also called *action*. For a list of events, see "Event Types" on page 87 in the PBS Professional Hooks Guide.

Execution event hook

A hook that runs at an execution host. These hooks run after a job is received by MoM. Execution event hooks have names prefixed with "*execjob_*".

Execution host

A computer which runs PBS jobs. An *execution host* is a system with a single operating system (OS) image, a unified virtual memory space, one or more CPUs and one or more IP addresses. Systems like Linux clusters, which contain separate computational units each with their own OS, are collections of hosts. Systems such as the HPE 8600 are also collections of hosts.

An execution host can be comprised of one or more vnodes. On the HPE 8600, each blade is treated as a vnode. See "Vnode".

Execution queue

A queue from which a job can be executed.

Failover

The PBS complex can run a backup server. If the primary server fails, the secondary takes over without an interruption in service.

Failure action

The action taken when a hook fails to execute. Specified in the fail_action hook attribute. See "Using the fail_action Hook Attribute" on page 37 in the PBS Professional Hooks Guide.

Fairshare

A scheduling policy that prioritizes jobs according to how much of a specified resource is being used by, and has recently been used by, job submitters. Job submitters can be organized into groups and subgroups, so that jobs can also be prioritized according to those groups' resource usage. Users and groups can each be allotted a percentage of total resource usage. See "Using Fairshare" on page 138 in the PBS Professional Administrator's Guide.

File staging

File staging is the transfer of files between a specified storage location and the execution host. See "Stage in" and "Stage out".

Finished jobs

Jobs whose execution is done, for any reason:

- Jobs which finished execution successfully and exited
- Jobs terminated by PBS while running
- Jobs whose execution failed because of system or network failure
- Jobs which were deleted before they could start execution

Floating license

A unit of application license dynamically allocated (checked out) when a user begins using an application on some host (when the job starts), and deallocated (checked in) when a user finishes using the application (when the job ends).

Furnishing queue/complex

In peer scheduling, the queue/complex from which jobs are pulled to be run at another queue/complex

Generic group limit

A limit that applies separately to groups at the server or a queue. This is the limit for groups which have no individual limit specified. A limit for generic groups is applied to the usage across the entire group. A separate limit can be specified at the server and each queue.

Generic project limit

Applies separately to projects at the server or a queue. The limit for projects which have no individual limit specified. A limit for generic projects is applied to the usage across the entire project. A separate limit can be specified at the server and each queue.

Generic user limit

A limit that applies separately to users at the server or a queue. This is the limit for users who have no individual limit specified. A separate limit for generic users can be specified at the server and at each queue.

Group

A collection of system users. A user must be a member of at least one group, and can be a member of more than one group.

Group access, Access by group

Refers to access to PBS objects, such as the server, queues, and reservations. A user in the specified group is allowed access at the server, queues, and reservations

Group ID (GID)

Unique numeric identifier assigned to each group. See "Group".

Group limit

Refers to configurable limits on resources and jobs. This is a limit applied to the total used by a group, whether the limit is a generic group limit or an individual group limit.

History jobs

Jobs which will no longer execute at this server:

- Moved jobs
- Finished jobs

Hold

A restriction which prevents a job from being executed. When a job has a hold applied to it, it is in the *Held* (*H*) state. See section 2.44, "qhold", on page 150.

Hook

Hooks are custom executables that can be run at specific points in the execution of PBS. They accept, reject, or modify the upcoming action. This provides job filtering, patches or workarounds, and extends the capabilities of PBS, without the need to modify source code.

Host

A machine running an operating system. A host can be made up of one or more vnodes. All vnodes of a host share the same value for resources_available.host.

Host access, Access from host

Refers to user access at the server, queues, and reservations from the specified host

Hostname

A hostname is a string. A hostname is of the form <machine name>.<domain name>, where *domain name* is a hierarchical, dot-separated list of subdomains. A hostname cannot contain the following:

- A dot ("."), other than as a subdomain separator
- The commercial at sign, "@", as this is often used to separate a file from the host in a remote file name
- To prevent confusion with port numbers, a hostname cannot contain a colon (":")

HTT

Intel's Hyper-Threading Technology

Idle

A server daemon is idle when it is running, but only accepting handshake messages, not performing workload management.

Importing a hook

When you "import a hook" using `qmgr`, you're telling PBS which Python script to run when the hook is triggered.

Importing a hook configuration file

When you "import a hook configuration file" using `qmgr`, you're telling PBS which file should be stored as the configuration file for the specified hook.

Indirect resource

A shared vnode resource at vnode(s) where the resource is not defined, but which share the resource.

Individual group limit

Applies separately to groups at the server or a queue. This is the limit for a group which has its own individual limit specified. An individual group limit overrides the generic group limit, but only in the same context, for example, at a particular queue. The limit is applied to the usage across the entire group. A separate limit can be specified at the server and each queue.

Individual project limit

Applies separately to projects at the server or a queue. Limit for a project which has its own individual limit specified. An individual project limit overrides the generic project limit, but only in the same context, for example, at a particular queue. The limit is applied to the usage across the entire project. A separate limit can be specified at the server and each queue.

Individual user limit

Applies separately to users at the server or a queue. This is the limit for users who have their own individual limit specified. A limit for an individual user overrides the generic user limit, but only in the same context, for example, at a particular queue. A separate limit can be specified at the server and each queue.

Installation account

The account used by the administrator when installing PBS. Not the *pbsadmin* account used by PBS.

Interactive job

A job where standard input and output are connected to the terminal from which the job was submitted.

Job or Batch job

A unit of work managed by PBS. A *job* is a related set of tasks, created and submitted by the user. The user specifies the resources required by the job, and the processes that make up the job. When the user submits a job to PBS, the user is handing off these tasks to PBS to manage. PBS then schedules the job to be run, and manages the running of the job, treating the tasks as parts of a whole. A job is usually composed of a set of directives and a shell script.

Job array

A *job array* is a container for a collection of similar jobs submitted under a single job ID. It can be submitted, queried, modified and displayed as a unit. The jobs in the collection are called subjobs. For more on job arrays, see "Job Arrays", on page 153 of the PBS Professional User's Guide.

Job array identifier

The identifier returned upon success when submitting a job array.

Job array identifiers are a sequence number followed by square brackets:

<sequence number>[][.<server name>][@<server name>]

Example:

```
1234[]
```

Note that some shells require that you enclose a job array ID in double quotes.

The largest value that *sequence number* can be is set in the max_job_sequence_id server attribute. This attribute defaults to *9999999*. Minimum value for this attribute is *9999999*, and maximum is *999999999999*. After maximum for sequence number has been reached, job array IDs start again at *0*.

Job array range

A specification for a set of subjobs within a job array. When specifying a range, indices used must be valid members of the job array's indices. Format:

<sequence number>[<first>-<last>:<step>][.server][@new server]

first is the first index of the subjobs.

last is the last index of the subjobs.

step is the stepping factor.

Job ID, Job identifier

When a job is successfully submitted to PBS, PBS returns a unique identifier for the job. Format:

<sequence number>[.<server>][@<new server>]

The <server> portion indicates the name of the original server where the job was submitted.

The @<new server> portion indicates the current location of the job if it is not at the original server.

The largest value that *sequence number* can be is set in the max_job_sequence_id server attribute. This attribute defaults to *9999999*. Minimum value for this attribute is *9999999*, and maximum is *999999999999*. After maximum for sequence number has been reached, job IDs start again at *0*.

Job name, Job array name

A job name or job array name can be at most 230 characters. It must consist only of alphabetic, numeric, plus sign ("+"), dash or minus or hyphen ("-"), underscore ("_"), and dot or period (".") characters.

Default: if a script is used to submit the job, the job's name is the name of the script. If no script is used, the job's name is "*STDIN*".

Job state

A job exists in one of the possible states throughout its existence within the PBS system. For example, a job can be queued, running, or exiting. See "States" on page 361.

Job-specific ASAP reservation, ASAP reservation

Reservation created for a specific queued job, for the same resources the job requests. PBS schedules the reservation to run as soon as possible, and PBS moves the job into the reservation. Created when you use `pbs_rsub -Wqmove=<job ID>` on a queued job.

Job-specific now reservation, now reservation

Reservation created for a specific running job. PBS creates a job-specific now reservation on the same resources as the job is using, and moves the job into the reservation. The reservation is created and starts running immediately when you use `pbs_rsub --job <job ID>` on a running job.

Job-specific reservation

A reservation created for a specific job, for the same resources that the job requested.

Job-specific start reservation, start reservation

Reservation created for a specific job, for the same resources the job requests. PBS starts the job according to scheduling policy. When the job starts, PBS creates and starts the reservation, and PBS moves the job into the reservation. Created when you use `qsub -Wcreate_resv_from_job=true` to submit a job or when you `qalter` a job to set the job's create_resv_from_job attribute to *True*.

Job Submission Description Language (JSDL)

Language for describing the resource requirements of jobs.

Job-wide resource, server resource, queue resource

A job-wide resource, also called a server-level or queue-level resource, is a resource that is available to the entire job at the server or queue.

A job-wide resource is available to be consumed or matched at the server or queue if you set the server or queue resources_available.<resource name> attribute to the available or matching value. For example, you can define a custom resource called *FloatingLicenses* and set the server's resources_available.FloatingLicenses attribute to the number of available floating licenses.

Examples of job-wide resources are shared scratch space, application licenses, or walltime.

A job can request a job-wide resource for the entire job, but not for individual chunks. Job-wide resources are requested outside of a selection statement, in this form:

-l keyword=value[,keyword=value ...]

where *keyword* identifies either a consumable resource or a time-based resource such as walltime.

A resource request "outside of a selection statement" means that the resource request comes after "`-l`", but not after "`-lselect=`".

Kill a job

To terminate the execution of a job.

Leaf

An endpoint (a server, scheduler, or MoM daemon.)

License Manager Daemon (`lmx-serv-altair`)

Daemon that functions as the license server. ALM license server. See the *PBS Works Licensing Guide*.

License server

Manages licenses for PBS jobs. ALM license server. See the *PBS Works Licensing Guide*.

License Server List Configuration

One form of redundant license server configuration. A collection of "<port number>@<hostname>" settings, pointing to license servers managing Altair licenses. Each server on the list is tried in turn. There could be X licenses on <server1>, Y licenses on <server2>, and Z licenses on <server3>, and the total licenses available would actually be X+Y+Z, but a request must be satisfied only by one server at a time. The first running server is the only server queried. See the *PBS Works Licensing Guide*.

Limit

A maximum that can be applied in various situations:

- The maximum number of jobs that can be queued
- The maximum number of jobs that can be running
- The maximum number of jobs that can be queued and running
- The maximum amount of a resource that can be allocated to queued jobs
- The maximum amount of a resource that can be consumed at any time by running jobs
- The maximum amount of a resource that can be allocated to queued and running jobs

Linux-Windows complex, Windows-Linux complex

A PBS complex with a Linux server/scheduler/comm host and Windows execution and client hosts.

Load balance

Scheduling policy wherein jobs are distributed across multiple hosts to even out the workload on each host.

Manager

A person who has been granted Manager privilege by being listed in the server's managers attribute. A Manager is authorized to use all restricted capabilities of PBS. A PBS Manager may act upon the server, queues, or jobs. See "Manager" on page 491 in the PBS Professional Administrator's Guide.

Managing vnode

The vnode where a shared vnode resource is defined, and which manages the resource.

Master provisioning script, Master script (Hooks)

The script that makes up the provisioning hook.

Memory-only vnode

Represents a node board that has only memory resources (no CPUs).

Mixed-mode complex

A PBS complex with a Linux server/scheduler/comm host, Linux execution and client hosts, and Windows execution and client hosts.

MoM

The daemon which runs on an execution host, managing the jobs on that host. *MoM* is the informal name for the process called `pbs_mom`. One MoM runs on each execution host.

MoM runs each job when it receives a copy of the job from the server. MoM creates a new session that is as identical to the user's login session as possible. For example under Linux, if the user's login shell is `csh`, MoM creates a session in which `.login` is run as well as `.cshrc`. MoM returns the job's output to the user when directed to do so by the server.

MoM is a reverse-engineered acronym that stands for "Machine Oriented Mini-server".

Monitoring

The act of tracking and reserving system resources and enforcing usage policy. This covers both user-level and system-level monitoring as well as monitoring running jobs. Tools are provided to aid human monitoring of the PBS system as well.

Primary execution host MoM (was Mother Superior)

The MoM on the head or first host of a multihost job. This MoM controls the job, communicates with the server, and controls and consolidates resource usage information. When a job is to run on more than one execution host, the job is sent to the MoM on the primary execution host, which then starts the job.

Moved jobs

Jobs which were moved to another server

No longer used. See "Execution host".

Non-consumable resource

A non-consumable resource is a resource that is not reduced or taken up by being used. Examples of non-consumable resources are Boolean resources and walltime. See "Consumable vs. Non-consumable Resources" on page 231 in the PBS Professional Administrator's Guide.

Non-job event hook

A hook that is not directly related to a specific job. Non-job event hooks are periodic hooks, startup hooks, provisioning hooks, and reservation creation hooks.

Now reservation, job-specific now reservation

Reservation created for a specific running job. PBS creates a job-specific now reservation on the same resources as the job is using, and moves the job into the reservation. The reservation is created and starts running immediately when you use `pbs_rsub --job <job ID>` on a running job.

Object, PBS object

An element of PBS such as the server, a queue, or a reservation

Occurrence of a standing reservation

An instance of the standing reservation.

An occurrence of a standing reservation behaves like an advance reservation, with the following exceptions:

- While a job can be submitted to a specific advance reservation, it can only be submitted to the standing reservation as a whole, not to a specific occurrence. You can only specify *when* the job is eligible to run. See the `qsub(1B)` man page.
- When an advance reservation ends, it and all of its jobs, running or queued, are deleted, but when an occurrence ends, only its running jobs are deleted.

Each occurrence of a standing reservation has reserved resources which satisfy the resource request, but each occurrence may have its resources drawn from a different source. A query for the resources assigned to a standing reservation will return the resources assigned to the soonest occurrence, shown in the resv_nodes attribute reported by `pbs_rstat`.

Operator

This term means a person who has been granted Operator privilege by being listed in the server's operators attribute. An Operator can use some but not all of the restricted capabilities of PBS. See "Operator" on page 490 in the PBS Professional Administrator's Guide.

Overall limit

Limit on the total usage. In the context of server limits, this is the limit for usage at the PBS complex. In the context of queue limits, this is the limit for usage at the queue. An overall limit is applied to the total usage at the specified location. Separate overall limits can be specified at the server and each queue.

Owner, Job owner

The user who submitted a specific job to PBS.

Parameter

A *parameter* specifies an element of the behavior of a component of PBS. For example, MoMs have parameters specifying which events to log, or what the maximum load should be. Parameters are specified by editing the component's configuration files.

Parent vnode

For single-vnode machines, the only vnode is the parent vnode.

For multi-vnode machines, there is a vnode called the *parent vnode*. A parent vnode does not correspond to any actual hardware. The parent vnode is used to define any placement set information that is invariant for a given host. The parent vnode is also used to define dynamic host-level resources, and can be used to define shared resources. See "Parent Vnodes and Child Vnodes" on page 42 in the PBS Professional Administrator's Guide. We used to call this vnode the "natural vnode".

For multi-vnode machines, vnodes that represent hardware are called *child vnodes*. See "Child vnode" on page 3.

Node

A host

pbshook

Keyword used by `qmgr` to operate on built-in hooks.

PBS Entity

A user, group, or host

pbs module

The *pbs module* is an interface to PBS and the hook environment. The interface is made up of Python objects, which have attributes and methods. You can operate on these objects using Python code.

PBS Object

An element of PBS such as the server, a queue, or a reservation

PBS Administrator

Same as Administrator.

Linux: person with Manager privilege and root access.

Windows: person with Manager privilege who is a member of the local Administrators group.

A person who administers PBS, performing functions such as downloading, installing, upgrading, configuring, or managing PBS.

PBS Administrator is distinguished from "site administrator", although often these are the same person.

pbsadmin (Windows)

The account that is used to execute the PBS MoM, `pbs_mom`, via the Service Control Manager on Windows. This must be "*pbsadmin*".

PBS_HOME

The path containing PBS files. The path under which PBS files are installed on the local system.

Default: `/var/spool/pbs`

PBS_EXEC

The path containing PBS executables. The path under which PBS executables are installed on the local system.

Default: `/opt/pbs`

PBS Professional

A workload management system consisting of a server, a scheduler, and any number of execution hosts each managed by a MoM. PBS accepts batch jobs from users, and schedules them on execution hosts according to the policy chosen by the site. PBS manages the jobs and their output according to site-specified policy.

Peer scheduling

A feature allowing different PBS complexes to automatically run each others' jobs. This way jobs can be dynamically load-balanced across the complexes. Each complex involved in peer scheduling is called a *peer*.

Placement set

A set of vnodes on which jobs can be run, selected so that the job will run as efficiently as possible. Placement sets are used to improve task placement (optimizing to provide a "good fit") by exposing information on system configuration and topology. See "Placement Sets" on page 167 in the PBS Professional Administrator's Guide.

Placement set series

The set of placement sets defined by a resource, where each set has the same value for the resource. If the resource takes on N values, there are N placement sets in the series. See "Placement Sets" on page 167 in the PBS Professional Administrator's Guide.

Placement pool

All of the placement sets defined at a PBS object. Each queue can have its own placement pool, and the server can have its own placement pool. See "Placement Sets" on page 167 in the PBS Professional Administrator's Guide.

Policy, Scheduling policy

The set of rules by which a scheduler selects jobs for execution.

POSIX

Refers to the various standards developed by the Technical Committee on Operating Systems and Application Environments of the IEEE Computer Society under standard P1003.

Preempt

Stop one or more running jobs in order to start a higher-priority job.

Preemption level

Job characteristic used to determine whether a job may preempt another or may be preempted, such as being in an express queue, having an owner who is over a soft limit, being a normal job, or having an owner who is over a fairshare allotment.

Preemption method

The method by which a job is preempted. This can be checkpointing, suspension, or requeueing.

Preemption target

A preemption target is a job in a specified queue or a job that has requested a specified resource. The queue and/or resource is specified in another job's Resource_List.preempt_targets.

Pre-execution event hook

A hook that runs before the job is accepted by MoM. These hooks do not run on execution hosts. Pre-execution event hooks are for job submission, moving a job, altering a job, or just before sending a job to an execution host.

Primary scheduler

The PBS Professional scheduler daemon which is running during normal operation.

Primary execution host

The execution host where a job's top task runs, and where the MoM that manages the job runs.

Primary server

The PBS Professional server daemon which is running during normal operation.

Primetime and non-primetime

An arbitrary, defined set of time slots during which scheduling follows the rules specified for primetime. By default primetime is 24/7, but you can define it to be any desired time slots. If a time slot is not primetime, it is non-primetime, during which scheduling follows non-primetime rules. There are default behaviors for primetime and non-primetime, but you can set up the behavior you want for each type. You can also define primetime and non-primetime queues. Jobs in a primetime queue run only during primetime, and jobs in non-primetime queues run only during non-primetime. See "Using Primetime and Holidays" on page 189 in the PBS Professional Administrator's Guide.

Project

In PBS, a project is a way to group jobs independently of users and groups. A project is a tag that identifies a set of jobs. Each job's project attribute specifies the job's project.

Project limit

This is a limit applied to the total used by a project, whether the limit is a generic project limit or an individual project limit.

Provision

To install an OS or application, or to run a script which performs installation and/or setup

Provisioned vnode

A vnode which, through the process of provisioning, has an OS or application that was installed, or which has had a script run on it

Provisioning hook

The hook which performs the provisioning, either by calling other scripts or by running commands

Provisioning tool

A tool that performs the actual provisioning, e.g. HPE Performance Cluster Manager (HPCM).

Pulling queue

In peer scheduling, the queue into which jobs are pulled, and from which they are run

Queue

A *queue* is a named container for jobs at a server. There are two types of queues in PBS: routing queues and execution queues. A *routing queue* is a queue used to move jobs to other queues including those that exist on other PBS servers. A job must reside in an *execution queue* to be eligible to run and remains in an execution queue during the time it is running. In spite of the name, jobs in a queue need not be processed in queue order (first-come first-served or *FIFO*).

Queuing

The collecting together of work or tasks to be run on a computer. Users submit tasks or "jobs" to the resource management system where they are queued up until the system is ready to run them.

Redundant License Server Configuration

Allows licenses to continue to be available should one or more license servers fail. There are two types: 1) license server list configuration, and 2) three-server configuration. See the *PBS Works Licensing Guide*.

Reject an action (Hooks)

An action is *rejected* when a hook prevents the action from taking place.

Requeue

The process of stopping a running job and putting it back into the *queued* ("*Q*") state.

Rerunnable

If a running PBS job can be terminated and then restarted from the beginning without harmful side effects, the job is rerunnable. The job's Rerunnable attribute must be set to *y* in order for PBS to consider a job to be rerunnable.

Reservation degradation

PBS attempts to ensure that reservations run by finding usable vnodes when reservation vnodes become unavailable.

Reservation ID, reservation identifier

When a reservation is successfully submitted to PBS, PBS returns a unique identifier for the reservation.

Format for advance reservation:

R<sequence number>[.server][@new server]

Format for standing reservation:

S<sequence number>[.server][@new server]

Format for maintenance reservation:

M<sequence number>[.server][@new server]

Resource

A *resource* can be something used by a job, such as CPUs, memory, high-speed switches, scratch space, application licenses, or time, or it can be an arbitrary item defined for another purpose. PBS has built-in resources, and allows custom-defined resources. See "Using PBS Resources" on page 227 in the PBS Professional Administrator's Guide.

Restart

A job that was stopped after being checkpointed while previously executing is executed again, starting from the point where it was checkpointed.

Restart File

The job-specific file that is written by the checkpoint script or tool. This file contains any information needed to restart the job from where it was when it was checkpointed.

Restart Script

The script that MoM runs to restart a job. This script is common to all jobs, and so must use the information in a job's restart file to restart the job.

Route a job

When PBS moves a job between queues. PBS provides a mechanism whereby a job is automatically moved from a routing queue to another queue. This is performed by PBS. The resource request for each job in a routing queue is examined, and the job is placed in a destination queue which matches the resource request. The destination queue can be an execution queue or another routing queue.

Routing queue

A queue that serves as a temporary holding place for jobs, before they are moved to another queue. Jobs cannot run from routing queues.

Scheduler

A scheduler is a daemon which implements some or all of the site's job scheduling policy controlling when and where each job is run. A scheduler is a process called `pbs_sched`.

Scheduling

The process of selecting which jobs to run when and where, according to a predetermined policy. Sites balance competing needs and goals on the system(s) to maximize efficient use of resources (both computer time and people time).

Scheduling policy

Scheduling policy determines when each job runs, and and how much of each resource it can use. Scheduling policy consists of a system for determining the priority of each job, combined with a set of limits on how many jobs can be run, and/or how much of each resource can be used.

Schema Admins (Windows)

A group that exists only in the root domain of an Active Directory forest of domains. The group is authorized to make schema changes in Active Directory.

Secondary scheduler

The PBS Professional scheduler daemon which takes over when the primary scheduler is not available.

Secondary server

The PBS Professional server daemon which takes over when the primary server fails.

Sequence number

The numeric part of a job ID, job array ID, or reservation ID, for example, *1234*. The largest value that can be used for a sequence number is set in the max_job_sequence_id job attribute.

Server

The central PBS daemon, which does the following:

- Handles PBS commands
- Receives and creates batch jobs
- Sends jobs for execution

The server is the process called `pbs_server`.

Each PBS complex has one primary server, and if the complex is configured for failover, a secondary server.

The server contains a licensing client which communicates with the licensing server for licensing PBS jobs.

PBS provides a default server; see "Default server" on page 5.

Server name

A server name is an ASCII character string. Format:

<hostname>[:<port number>]

The network routine `gethostbyname` is used to translate this to a network address. The network routine `getservbyname` is used to determine the port number. An alternate port number may be specified by appending a colon (":") and the port number to the hostname.

Shared resource

A vnode resource defined and managed at one vnode, but available for use at others.

Shrink-to-fit job

A job that requests the min_walltime resource. A shrink-to-fit job requests a running time in a specified range, where min_walltime is required, and max_walltime is not. PBS computes the actual walltime.

Sister

Any MoM that is not on the head or first host of a multihost job. A sister is directed by the primary execution host. Also called a *subordinate MoM*.

Sisterhood

All of the MoMs involved in running a particular job.

Site

A location which for our purposes uses (or will use) PBS. A site can employ one or more PBS complexes, each made up of any combination of hardware and software that PBS supports.

Snapshot Checkpoint

The checkpoint script or tool writes a restart file, and the job continues to execute. The job resumes from this start file if the system experiences a problem during the job's subsequent execution.

Soonest occurrence of a standing reservation

The occurrence which is currently active, or if none is active, it is the next occurrence.

Stage in

The process of moving one or more job-related files from a storage location to the execution host before running the job.

Stage out

The process of moving one or more job-related files from the execution host to a storage location after running the job.

Staging and execution directory

The *staging and execution directory* is a directory on the execution host where the following happens:

- Files are staged into this directory before execution
- The job runs in this directory
- Files are staged out from this directory after execution

A job-specific staging and execution directory can be created for each job, or PBS can use a specified directory, or a default directory. See "Staging and Execution Directories for Job" on page 473 in the PBS Professional Administrator's Guide.

Standing reservation

An advance reservation which recurs at specified times. For example, the user can reserve 8 CPUs and 10GB every Wednesday and Thursday from 5pm to 8pm, for the next three months.

Start reservation, Job-specific start reservation

Reservation created for a specific queued job, for the same resources the job requests. PBS starts the job according to scheduling policy. When the job starts, PBS creates and starts the reservation, and PBS moves the job into the reservation. Created when you use `qsub -Wcreate_resv_from_job=true` on a queued job.

State

The PBS server, vnodes, reservations, and jobs can be in various states, depending on what PBS is doing. For example the server can be *idle* or *scheduling*, vnodes can be *busy* or *free*, and jobs can be *queued* or *running*, among other states. For a complete description of states, see "States" on page 361.

Strict ordering

A scheduling policy where jobs are run according to policy order. If the site-specified policy dictates a particular priority ordering for jobs, that is the order in which they are run. Strict ordering can be modified by backfilling in order to increase throughput. See "Backfilling".

Subject

A process belonging to a job run by an authorized, unprivileged user (a job submitter.)

Subjob

One of the jobs in a job array, e.g. `1234[7]`, where `1234[]` is the job array itself, and 7 is the index. Queued subjobs are not individually listed in the queue; only their job array is listed. Running subjobs are individually listed.

Subjob index

The unique index which differentiates one subjob from another. This must be a non-negative integer.

Subordinate MoM

Any MoM that is not on the head or first host of a multihost job. A subordinate MoM is directed by the primary execution host. Also called a *sister*.

Task

A process belonging to a job. A POSIX session started by MoM on behalf of a job.

Task placement

The process of choosing a set of vnodes to allocate to a job that will both satisfy the job's resource request (select and place specifications) and satisfy the configured scheduling policy.

Three-server configuration

One form of redundant license server configuration. Means that if any 2 of the 3 license servers are up and running (referred to as a quorum), the system is functional, with 1 server acting as master who can issue licenses. If the master goes down, another server must take over as master. See the *PBS Works Licensing Guide*.

TPP

TCP-based Packet Protocol. Protocol used by `pbs_comm`.

User

Has two meanings:

1. A person who submits jobs to PBS, as differentiated from Operators, Managers and administrators. See "User" on page 490 in the PBS Professional Administrator's Guide.
2. A system user, identified by a unique character string (the user name) and by a unique number (the user ID). Any person using the system has a username and user ID.

User access, Access by user

The specified user is allowed access at the server, queues, and reservations .

User ID, UID

A unique numeric identifier assigned to each user.

User limit

Refers to configurable limits on resources and jobs. A limit placed on one or more users, whether generic or individual.

Vchunk

The part of a chunk that is supplied by one vnode. If a chunk is broken up across multiple vnodes, each vnode supplies a vchunk.

Version 1 configuration file

MoM configuration file containing MoM configuration parameters. See Chapter 3, "MoM Parameters", on page 243.

Version 2 configuration file

Also called vnodedefs file. Vnode configuration file containing vnode attribute and resource settings. Created using `pbs_mom -s insert` command. See "Version 2 Vnode Configuration Files" on page 46 in the PBS Professional Administrator's Guide.

Virtual processor, VP

PBS can treat a vnode as if it has more processors available than the number of physical processors. When resources_available.ncpus is set to a number higher than the actual number of physical processors, the vnode can be said to have virtual processors. Also called logical processors.

Vnode

A virtual node, or *vnode*, is an abstract object representing a host or a set of resources which form a usable part of an execution host. This could be an entire host, or a nodeboard or a blade. A single host can be made up of multiple vnodes. Each vnode can be managed and scheduled independently. Each vnode in a complex must have a unique name. Vnodes on a host can share resources, such as node-locked licenses.

vnodedefs file

A Version 2 configuration file. Vnode configuration file containing vnode attribute and resource settings. Created using `pbs_mom -s insert` command. See "Version 2 Vnode Configuration Files" on page 46 in the PBS Professional Administrator's Guide.

vp

Virtual processor. The smallest unit of execution resources that can be specified to run a job.

Windows-Linux complex, Linux-Windows complex

A PBS complex with a Linux server/scheduler/comm host and Windows execution and client hosts.

2
PBS Commands

The commands described in this chapter work with a live PBS Professional complex; you cannot use these implementations on a simulation. The Simulate feature uses commands that are implemented for use with simulations; for those, see Chapter 3, "Simulate Command Reference", on page 21 of the *PBS Professional Simulate Guide*.

2.1 Our Command Notation

Optional Arguments

Optional arguments are enclosed in square brackets. For example, in the `qstat` man page, the `-E` option is shown this way:

qstat [-E]

To use this option, you would type:

```
qstat -E
```

Variable Arguments

Variable arguments (where you fill in the variable with the actual value) such as a job ID or vnode name are enclosed in angle brackets. Here's an example from the `pbsnodes` man page:

pbsnodes -v <vnode>

To use this command on a vnode named "my_vnode", you'd type:

```
pbsnodes -v my_vnode
```

Optional Variables

Optional variables are enclosed in angle brackets inside square brackets. In this example from the `qstat` man page, the job ID is optional:

qstat [<job ID>]

To query the job named "1234@my_server", you would type this:

```
qstat 1234@my_server
```

Literal Terms

Literal terms appear exactly as they should be used. For example, to get the version for a command, you type the command, then "--version". Here's the syntax:

qstat --version

And here's how you would use it:

```
qstat --version
```

Multiple Alternative Choices

When there are multiple options and you should choose one, the options are enclosed in curly braces. For example, if you can use either "-n" or "--name":

```
{-n | --name}
```

2.2 List of Commands

2.2.1 Requirements for Commands

Some PBS commands require root privilege or PBS Operator or Manager privilege in order to run. Some can be executed by anyone, but the output depends upon the privilege of the user.

Most PBS commands require that the server be running; some require that MoMs be running.

The following table lists the commands, and indicates the permissions required to use each, and whether the server or MoM must be running.

Table 2-1: PBS Commands

Command	Action	Permission Required	Server Must Be Running?	MoM Must Be Running?
mpiexec	Runs MPI programs under PBS on Linux	Any	No	No
pbs	Start, stop, restart, or get the PIDs of PBS daemons	Root on Linux; Admin on Windows	No	No
pbsdsh	Distributes tasks to vnodes under PBS	Root on Linux; Admin on Windows	No	Yes
pbsfs	Show or manipulate PBS fairshare usage data	Any	Yes	No
pbsnodes	Query PBS host or vnode status, mark hosts free or offline, change the comment for a host, or output vnode information	Result depends on permission	Yes	No
pbsrun	General-purpose wrapper script for `mpirun`	Root or PBS administrator only	No	No
pbsrun_unwrap	Unwraps `mpirun`, reversing `pbsrun_wrap`	Root on Linux	No	No
pbsrun_wrap	General-purpose script for wrapping `mpirun` in `pbsrun`	Root on Linux	No	No
pbs_account	For Windows. Manage PBS service account	Admin on Windows	No	No
pbs_attach	Attaches a session ID to a PBS job	Root, Admin, or job owner	Yes	Yes
pbs_comm	Starts the PBS communication daemon	Root on Linux	No	No
pbs_dataservice	Start, stop, or check the status of PBS data service	Root on Linux	No	No

Table 2-1: PBS Commands

Command	Action	Permission Required	Server Must Be Running?	MoM Must Be Running?
pbs_ds_password	Sets or changes data service user account or its password	Root on Linux; Admin on Windows	No	No
pbs_hostn	Reports hostname and network address(es)	Any	No	No
pbs_idled	Runs PBS daemon that monitors the console and informs pbs_mom of idle time	Root or PBS administrator only	No	No
pbs_iff	Tests authentication with the server	Any; useful only to root	Yes	No
pbs_interactive	For Windows. Register, unregister, or get the version of PBS_INTERACTIVE service	Administrator only	No	No
pbs_login	Caches encrypted user password for authentication	Any	No, for PBS service account Yes, for job submitters	No
pbs_mkdirs	For Windows. Create, or fix the permissions of, the directories and files used by PBS	PBS administrator only	No	No
pbs_mom	Runs the PBS job monitoring and execution daemon	Root on Linux; Admin on Windows	No	No
pbs_mpihp	Runs an MPI application in a PBS job with HP MPI	Any	Yes	Yes
pbs_mpirun	Runs MPI programs under PBS with MPICH	Any	Yes	Yes
pbs_probe	**Deprecated**. Reports PBS diagnostic information and fixes permission errors	Root or PBS administrator only	No	No
pbs_python	Python interpreter for debugging a hook script from the command line	Any	No	No
pbs_ralter	Modifies an existing advance, standing, or job-specific reservation	Job owner or PBS administrator	Yes	No
pbs_rdel	Deletes a PBS advance, standing, or job-specific reservation	Any	Yes	No

Table 2-1: PBS Commands

Command	Action	Permission Required	Server Must Be Running?	MoM Must Be Running?
pbs_release_nodes	Releases sister hosts or vnodes assigned to a PBS job	Job owner, PBS Manager, Operator, administrator, root on Linux, Admin on Windows	Yes	Yes
pbs_rstat	Shows status of PBS advance, standing, or job-specific reservations	Any	Yes	No
pbs_rsub	Creates a PBS advance, standing, or job-specific reservation	Any	Yes	No
pbs_sched	Runs a PBS scheduler	Root on Linux	No	No
pbs_server	Starts a PBS batch server	Root on Linux	No	No
pbs_snapshot	Linux only. Captures PBS workload and configuration data	Root on Linux	Yes	No
pbs_tclsh	**Deprecated**. TCL shell with TCL-wrapped PBS API	Any	No	No
pbs_tmrsh	TM-enabled replacement for `rsh/ssh` for use by MPI implementations	Any	No	Yes
pbs_topologyinfo	Reports topological information	Root or Windows administrator only	No	No
pbs_wish	**Deprecated**. TK window shell with TCL-wrapped PBS API	Any	No	No
printjob	Prints job information	Root or Windows Administrator only	No	No
qalter	Alters a PBS job	Any	Yes	No
qdel	Deletes PBS jobs	Any	Yes	No
qdisable	Prevents a queue from accepting jobs	Manager or Operator only	Yes	No
qenable	Allows a queue to accept jobs	Manager or Operator only	Yes	No
qhold	Holds PBS batch jobs	Some holds can be set by Operator, Manager, root, or administrator only	Yes	No
qmgr	Administrator's command interface for managing PBS	Any	Yes	No

Table 2-1: PBS Commands

Command	Action	Permission Required	Server Must Be Running?	MoM Must Be Running?
qmove	Moves a PBS job from one queue to another	Any; managers and operators can move jobs in some cases where unprivileged users cannot	Yes	No
qmsg	Writes message string into one or more job output files	Any	Yes	No
qorder	Swaps queue positions of two PBS jobs	Any	Yes	No
qrerun	Requeues a PBS job	Manager or Operator only	Yes	No
qrls	Releases holds on PBS jobs	Some holds can be released by Operator, Manager, root, or administrator only	Yes	No
qrun	Runs a PBS job immediately	Operator or Manager only	Yes	No
qsig	Selects specified PBS jobs	Any	Yes	No
qsig	Send signal to PBS job	Operator or Manager required to send *admin-suspend*, *admin-resume*, *suspend*, and *resume*. Any privilege for other signals.	Yes	Yes
qstart	Turns on scheduling or routing for the jobs in a PBS queue	Operator or Manager only	Yes	No
qstat	Displays status of PBS jobs, queues, or servers	Result depends on permission	Yes	No
qstop	Prevents PBS jobs in the specified queue from being scheduled or routed	Operator or Manager only	Yes	No
qsub	Submits a job to PBS	Any	Yes	No
qterm	Terminates one or both PBS servers, and optionally terminates scheduler and/or MoMs	Operator or Manager only	Yes	No
tracejob	Extracts and prints log messages for a PBS job	Root or PBS administrator only	No	No
win_postinstall.py	For Windows. Configures PBS services	Administrator	No	No

2.2.2 Windows Requirements

Under Windows, use double quotes when specifying arguments to PBS commands.

2.3 mpiexec

Runs MPI programs under PBS on Linux

2.3.1 Synopsis

mpiexec

mpiexec --version

2.3.2 Description

The PBS `mpiexec` command provides the standard `mpiexec` interface on a system running supported versions of HPE MPI. If executed on a different system, it will assume it was invoked by mistake. In this case it will use the value of PBS_O_PATH to search for the correct `mpiexec`. If one is found, the PBS `mpiexec` will exec it.

The PBS `mpiexec` calls the HPE `mpirun(1)`.

It is transparent to the user; MPI jobs submitted outside of PBS run as they would normally. MPI jobs can be launched across multiple HPE systems. PBS will manage, track, and cleanly terminate multi-host MPI jobs. PBS users can run an MPI job within a specific partition.

If CSA has been configured and enabled, PBS will collect accounting information on all tasks launched by an MPI job. CSA information will be associated with the PBS job ID that invoked it, on each execution host.

If the PBS_MPI_DEBUG environment variable's value has a nonzero length, PBS writes debugging information to standard output.

2.3.3 Usage

The PBS `mpiexec` command presents the `mpiexec` interface described in section "4.1 Portable MPI Process Startup" of the "MPI-2: Extensions to the Message-Passing Interface" document in `http://www.mpifo-rum.org/docs/mpi-20-html/node42.htm`

2.3.4 Options

--version

The `mpiexec` command returns its PBS version information and exits. This option can only be used alone.

2.3.5 Requirements

- System running a supported version of HPE MPI.
- PBS uses HPE's `mpirun(1)` command to launch MPI jobs. HPE's `mpirun` must be in the standard location.
- The location of `pbs_attach()` on each vnode of a multi-vnode MPI job must be the same as it is on the primary execution host vnode.
- In order to run multihost jobs, the HPE Array Services must be correctly configured. HPE systems communicating via HPE's Array Services must all use the same version of the `sgi-arraysvcs` package. HPE systems communicating via HPE's Array Services must have been configured to interoperate with each other using the default array. See HPE's `array_services(5)` man page.

2.3.6 Environment Variables

PBS_ENVIRONMENT

The PBS_ENVIRONMENT environment variable is used to determine whether `mpiexec` is being called from within a PBS job.

PBS_MPI_DEBUG

The PBS `mpiexec` checks the PBS_MPI_DEBUG environment variable. If this variable has a nonzero length, debugging information is written.

PBS_O_PATH

The PBS `mpiexec` uses the value of PBS_O_PATH to search for the correct `mpiexec` if it was invoked by mistake.

2.3.7 Path

PBS' `mpiexec` is located in `PBS_EXEC/bin/mpiexec`.

2.3.8 See Also

The PBS Professional Administrator's Guide, "pbs_attach" on page 56

HPE man pages: HPE's `mpirun(1)`, HPE's `mpiexec_mpt(1)`, HPE's `array_services(5)`

2.4 pbs

Start, stop, restart, or get the PIDs of PBS daemons

2.4.1 Synopsis

pbs [start | stop | restart | status]

2.4.2 Description

The `pbs` command starts, stops or restarts all PBS daemons on the local machine, or reports the PIDs of all daemons when given the *status* argument. Does not affect other hosts.

You can start, stop, restart, or status the PBS daemons using the `systemctl` command; see "Starting & Stopping PBS on Linux" on page 141 in the PBS Professional Installation & Upgrade Guide.

2.4.2.1 Caveats

This command operates only on daemons that are marked as active in `pbs.conf`. For example, if PBS_START_MOM is set to *0* in the local `pbs.conf`, this command will not operate on `pbs_mom`, and will not start, stop, or restart `pbs_mom`.

This command is typically placed in `/etc/init.d` so that PBS starts up automatically.

2.4.2.2 Required Privilege

You need root privilege to use this command to start, stop, or restart PBS daemons.

A non-root user can use this command to get the PIDs of PBS daemons.

2.4.3 Arguments

restart
: All daemons on the local machine are stopped, then they are restarted. PBS reports the name of the license server and the number and type of licenses available.

start
: Each daemon on the local machine is started. PBS reports the number and type of licenses available, as well as the name of the license server. Any running jobs are killed.

status
: PBS reports the PID of each daemon on the local machine.

stop
: Each daemon on the local machine is stopped, and its PID is reported.

2.5 pbsdsh

Distributes tasks to vnodes under PBS

2.5.1 Synopsis

pbsdsh [-c <copies>] [-s] [-v] [-o] -- <program> [<program args>]

pbsdsh [-n <vnode index>] [-s] [-v] [-o] -- <program >[<program args>]

pbsdsh --version

2.5.2 Description of `pbsdsh` Command

The `pbsdsh` command allows you to distribute and execute a task on each of the vnodes assigned to your job by executing (spawning) the application on each vnode. The `pbsdsh` command uses the PBS Task Manager, or TM, to distribute the program on the allocated vnodes.

When run without the `-c` or the `-n` option, `pbsdsh` will spawn the program on all vnodes allocated to the PBS job. The spawns take place concurrently; all execute at (about) the same time.

Note that the double dash must come after the options and before the program and arguments. The double dash is only required for Linux.

The `pbsdsh` command runs one task for each line in the $PBS_NODEFILE. Each MPI rank gets a single line in the $PBS_NODEFILE, so if you are running multiple MPI ranks on the same host, you still get multiple `pbsdsh` tasks on that host.

2.5.2.1 Example

The following example shows the `pbsdsh` command inside of a PBS batch job. The options indicate that the user wants `pbsdsh` to run the *myapp* program with one argument (*app-arg1*) on all four vnodes allocated to the job (i.e. the default behavior).

```
#!/bin/sh
#PBS -l select=4:ncpus=1
#PBS -l walltime=1:00:00

pbsdsh ./myapp app-arg1
```

2.5.3 Options to `pbsdsh` Command

-c <copies>

The program is spawned *copies* times on the vnodes allocated, one per vnode, unless *copies* is greater than the number of vnodes. If *copies* is greater than the number of vnodes, it wraps around, running multiple instances on some vnodes. This option is mutually exclusive with `-n`.

-n <vnode index>

The program is spawned only on a single vnode, which is the *vnode index*-th vnode allocated. This option is mutually exclusive with `-c`.

-o

No obit request is made for spawned tasks. The program does not wait for the tasks to finish.

-s
The program is run in turn on each vnode, one after the other.

-v
Produces verbose output about error conditions and task exit status.

--version
The pbsdsh command returns its PBS version information and exits. This option can only be used alone

2.5.4 Operands

program
The first operand, *program*, is the program to execute. The double dash must precede *program* under Linux.

program args
Additional operands, *program args*, are passed as arguments to the program.

2.5.5 Standard Error

The pbsdsh command writes a diagnostic message to standard error for each error occurrence.

2.5.6 Caveats

The pbsdsh command does not check for host availability. This can lead to the following problems:

- If you run pbsdsh while one of the hosts is down, pbsdsh enters an infinite loop
- If you restart the primary execution host while pbsdsh is running, pbsdsh exits with an error because it loses connection with MoM on the primary
- Starting pbsdsh right after a host restart may result in an error on task spawn because the task can be sent to the host before the host rejoins the job (and receives ports through which it should communicate)

2.6 pbsfs

Show or manipulate PBS fairshare usage data

2.6.1 Synopsis

Showing usage data:

pbsfs [-c <entity1> <entity2>] [-g <entity>] [-I <scheduler name>] [-p] [-t]

Manipulating usage data:

pbsfs [-d] [-e] [-I <scheduler name>] [-s <entity> <usage value>]

Printing version:

pbsfs --version

2.6.2 Description

You can use the `pbsfs` command to print or manipulate a PBS scheduler's fairshare usage data. You can print the usage data in various formats, described below. Changes made using `pbsfs` take effect in the next scheduling cycle; you do not need to restart or HUP a scheduler for changes to take effect.

We recommend that if you use the options that manipulate usage data, you should do this when a scheduler is not scheduling jobs, because scheduling while changing fairshare usage data may give unwanted results.

2.6.2.1 Prerequisites

The server must be running in order to use the `pbsfs` command.

2.6.2.2 Permissions

You must be root to run the `pbsfs` command; if not, it will print the error message, "`Unable to access fairshare data`".

2.6.3 Options to `pbsfs`

You can safely use the following options while jobs are being scheduled:

(no options)

Same as `pbsfs -p`.

-c <entity1> <entity2>

Compares two fairshare entities.

-g <entity>

Prints a detailed listing for the specified entity, including the path from the root of the tree to the entity.

-I <scheduler name>

Specifies name of scheduler whose data is to be manipulated or shown. Required for multischeds; optional for default scheduler. Name of default scheduler is "default". If not specified, `pbsfs` operates on default scheduler.

-p

Prints the fairshare tree as a table, showing for each internal and leaf vertex the group ID of the vertex's parent, group ID of the vertex, vertex shares, vertex usage, and percent of shares allotted to the vertex.

-t

Prints the fairshare tree in a hierarchical format.

--version

The pbsfs command returns its PBS version information and exits. This option can only be used alone.

It is not recommended to be scheduling jobs when you use the following options:

-d

Decays the fairshare tree by the amount specified in the fairshare_decay_factor scheduler parameter.

-e

Trims fairshare tree to just the entities in the resource_group file. Unknown entities and their usage are deleted; as a result the unknown group has no usage and no children.

-s <entity> <usage value>

Sets *entity*'s usage value to *usage value*. Editing a non-leaf entity is ignored. All non-leaf entity usage values are calculated each time you use the pbsfs command to make changes.

2.6.3.1 Output Formats for pbsfs

The pbsfs command can print output in three different formats:

pbsfs -g <entity>

Prints a detailed listing for the specified entity. Example:

```
pbsfs -g pbsuser3
fairshare entity: pbsuser3
Resgroup: 20
cresgroup: 22
Shares: 40
Percentage: 24.000000%
fairshare_tree_usage: 0.832973
usage: 1000 (cput)
usage/perc: 4167
Path from root:
TREEROOT  :     0       1201 / 1.000 = 1201
group2    :    20       1001 / 0.600 = 1668
pbsuser3  :    22       1000 / 0.240 = 4167
```

pbsfs,

pbsfs -p

Prints the entire tree as a table, with data in columns. Example:

```
pbsfs
Fairshare usage units are in: cput
TREEROOT  : Grp: -1     cgrp: 0    Shares: -1     Usage: 1201   Perc: 100.000%
group2    : Grp: 0      cgrp: 20   Shares: 60     Usage: 1001   Perc: 60.000%
pbsuser3  : Grp: 20     cgrp: 22   Shares: 40     Usage: 1000   Perc: 24.000%
pbsuser2  : Grp: 20     cgrp: 21   Shares: 60     Usage: 1      Perc: 36.000%
group1    : Grp: 0      cgrp: 10   Shares: 40     Usage: 201    Perc: 40.000%
pbsuser1  : Grp: 10     cgrp: 12   Shares: 50     Usage: 100    Perc: 20.000%
pbsuser   : Grp: 10     cgrp: 11   Shares: 50     Usage: 100    Perc: 20.000%
unknown   : Grp: 0      cgrp: 1    Shares: 0      Usage: 1      Perc: 0.000%
```

pbsfs -t

Prints the entire tree as a tree, showing group-child relationships. Example:

```
pbsfs -t
  TREEROOT(0)
      group2(20)
           pbsuser3(22)
           pbsuser2(21)
      group1(10)
           pbsuser1(12)
           pbsuser(11)
      unknown(1)
```

2.6.3.2 Data Output by pbsfs

cresgroup, cgrp

Group ID of the entity

fairshare entity

The specified fairshare tree entity

fairshare usage units

The resource for which a scheduler accumulates usage for fairshare calculations. This defaults to *cput* (CPU seconds) but can be set in a scheduler's configuration file.

fairshare_tree_usage

The entity's effective usage. See "Computing Effective Usage (fairshare_tree_usage)" on page 144 in the PBS Professional Administrator's Guide.

Path from root

The path from the root of the tree to the entity. A scheduler follows this path when comparing priority between two entities.

Percentage, perc

The percentage of the shares in the tree allotted to the entity, computed as fairshare_perc. See "Computing Target Usage for Each Vertex (fairshare_perc)" on page 144 in the PBS Professional Administrator's Guide.

Resgroup, Grp

Group ID of the entity's parent group

Shares
: The number of shares allotted to the entity

usage
: The amount of usage by the entity

usage/perc
: The value a scheduler uses to the pick which entity has priority over another. The smaller the number the higher the priority.

2.6.4 See Also

"Using Fairshare" on page 138 in the PBS Professional Administrator's Guide.

2.7 pbsnodes

Query PBS host or vnode status, mark hosts free or offline, change the comment for a host, or output vnode information

2.7.1 Synopsis

pbsnodes [-o | -r] [-s <server name>] [-C <comment>] <hostname> [<hostname> ...]

pbsnodes [-l] [-s <server name>]

pbsnodes -v <vnode> [<vnode> ...] [-s <server name>]

pbsnodes -a[v] [-S[j][L]] [-F json|dsv [-D <delimiter>]] [- s <server name>]

pbsnodes [-H] [-S[j][L]] [-F json|dsv [-D <delimiter>]] <hostname> [<hostname> ...]

pbsnodes --version

2.7.2 Description

The `pbsnodes` command is used to query the status of hosts or vnodes, to mark hosts *FREE* or *OFFLINE*, to edit a host's comment attribute, or to output vnode information. The `pbsnodes` command obtains host information by sending a request to the PBS server.

2.7.2.1 Using pbsnodes

To list all vnodes:

```
pbsnodes -av
```

To print the status of the specified host or hosts, run `pbsnodes` with no options (except the `-s` option) and with a list of hosts.

To print the command usage, run `pbsnodes` with no options and without a list of hosts.

To remove a vnode from the scheduling pool, mark it *OFFLINE*. If it is marked *DOWN*, when the server next queries the MoM, and can connect, the vnode will be marked *FREE*.

To offline a single vnode in a multi-vnoded system, use:

```
qmgr -c "set node <vnode name> state=offline"
```

2.7.2.2 Output

The order in which hosts or vnodes are listed in the output of the `pbsnodes` command is undefined. Do not rely on output being ordered.

If you print attributes, `pbsnodes` prints out only those attributes which are not at default values.

2.7.2.3 Permissions

PBS Manager or Operator privilege is required to execute `pbsnodes` with the `-o` or `-r` options, to view custom resources which have been created to be invisible to users, and to see some output such as PBS version.

2.7.3 Options to pbsnodes

(no options)

If neither options nor a host list is given, the pbsnodes command prints usage syntax.

-a

Lists all hosts and all their attributes (available and used.)

When used with the -v option, lists all vnodes.

When listing a host with multiple vnodes:

The output for the jobs attribute lists all the jobs on all the vnodes on that host. Jobs that run on more than one vnode will appear once for each vnode they run on.

For consumable resources, the output for each resource is the sum of that resource across all vnodes on that host.

For all other resources, e.g. string and Boolean, if the value of that resource is the same on all vnodes on that host, the value is returned. Otherwise the output is the literal string "<various>".

-C <comment>

Sets the comment attribute for the specified host(s) to the value of *comment*. Comments containing spaces must be quoted. The comment string is limited to 80 characters. Usage:

```
pbsnodes -C <comment> <hostname> [<hostname> ...]
```

To set the comment for a vnode:

```
qmgr -c "s n <vnode name> comment=<comment>"
```

-F dsv [-D <delimiter>]

Prints output in delimiter-separated value format. Optional delimiter specification. Default delimiter is vertical bar ("|").

-F json

Prints output in JSON format.

-H <hostname> [<hostname> ...]

Prints all non-default-valued attributes for specified hosts and all vnodes on specified hosts.

-j

Displays the following job-related headers for specified vnodes:

Table 2-2: Output for -j Option

Header	Width	Description
vnode	15	Vnode name
state	15	Vnode state
njobs	6	Number of jobs on vnode
run	5	Number of running jobs at vnode
susp	6	Number of suspended jobs at vnode
mem f/t	12	Vnode memory free/total
ncpus f/t	7	Number of CPUs at vnode free/total
nmics f/t	7	Number of MICs free/total
ngpus f/t	7	Number of GPUs at vnode free/total
jobs	No restriction	List of job IDs on vnode

Note that nmics is a custom resource that must be created by the administrator if you want it displayed here.

Each subjob is treated as a unique job.

-L

Displays output with no restrictions on column width.

-l

Lists all hosts marked as *DOWN* or *OFFLINE*. Each such host's state and comment attribute (if set) is listed. If a host also has state *STATE-UNKNOWN*, it is listed. For hosts with multiple vnodes, only hosts where all vnodes are marked as *DOWN* or *OFFLINE* are listed.

-o <hostname> [<hostname> ...]

Marks listed hosts as *OFFLINE* even if currently in use. This is different from being marked *DOWN*. A host that is marked *OFFLINE* continues to execute the jobs already on it, but is removed from the scheduling pool (no more jobs are scheduled on it.)

For hosts with multiple vnodes, `pbsnodes` operates on a host and all of its vnodes, where the hostname is resources_available.host, which is the name of the parent vnode.

To offline all vnodes on a multi-vnoded machine:

```
pbsnodes -o <name of parent vnode>
```

To offline a single vnode on a multi-vnoded system, use:

```
Qmgr: qmgr -c "set node <vnode name> state=offline"
```

Requires PBS Manager or Operator privilege.

-r <hostname> [<hostname> ...]

Clears *OFFLINE* from listed hosts.

-S

Displays the following vnode information:

Table 2-3: Output for -S Option

Header	Width	Description
name	15	Vnode name
state	15	Vnode state
OS	8	Value of OS custom resource, if any
hardware	8	Value of hardware custom resource, if any
host	15	Hostname
queue	10	Value of vnode's queue attribute
ncpus	7	Number of CPUs at vnode
nmics	7	Number of MICs at vnode
mem	8	Vnode memory
ngpus	7	Number of GPUs at vnode
comment	No restriction	Vnode comment

Note that nmics and OS are custom resources that must be created by the administrator if you want their values displayed here.

-s <server name>

Specifies the PBS server to which to connect.

-v [<vnode> [<vnode> ...]]

Lists all non-default-valued attributes for each specified vnode.

With no arguments, prints one entry for each vnode in the PBS complex.

With one or more vnodes specified, prints one entry for each specified vnode.

When used with `-a`, lists all vnodes.

--version

The `pbsnodes` command returns its PBS version information and exits. This option can only be used alone.

2.7.4 Operands

<server name>

Specifies the server to which to connect. Default: default server.

<hostname> [<hostname> ...]

Specifies the host(s) to be queried or operated on.

<vnode> [<vnode> ...]

Specifies the vnode(s) to be queried or operated on.

2.7.5 Exit Status

Zero

Success

Greater than zero

- Incorrect operands are given
- `pbsnodes` cannot connect to the server
- There is an error querying the server for the vnodes

2.7.6 See Also

The PBS Professional Administrator's Guide, "qmgr" on page 152

2.8 pbsrun

General-purpose wrapper script for mpirun

2.8.1 Synopsis

pbsrun

pbsrun --version

2.8.2 Description

pbsrun is a wrapper script for any of several versions of mpirun. This provides a user-transparent way for PBS to control jobs which call mpirun in their job scripts. The pbsrun_wrap script instantiates pbsrun so that the wrapper script for the specific version of mpirun being used has the same name as that version of mpirun.

If the mpirun wrapper script is run inside a PBS job, it translates any mpirun call of the form:

mpirun [<options>] <executable> [<args>]

into

mpirun [<options>] pbs_attach [<special options to pbs_attach>] <executable> [<args>]

where *special options* refers to any option needed by pbs_attach to do its job (e.g. *-j $PBS_JOBID*).

If the wrapper script is executed outside of PBS, a warning is issued about "not running under PBS", but it proceeds as if the actual program had been called in standalone fashion.

The pbsrun wrapper script is not meant to be executed directly; instead it is instantiated by pbsrun_wrap. It is copied to the target directory and renamed "pbsrun.<mpirun version/flavor>" where *mpirun version/flavor* is a string that identifies the mpirun version being wrapped (e.g. *ch_gm*).

The pbsrun script, if executed inside a PBS job, runs an initialization script, named $PBS_EXEC/lib/MPI/pbsrun.<mpirun version/flavor>.init, then parses mpirun-like arguments from the command line, sorting which options and option values to retain, to ignore, or to transform, before calling the actual mpirun script with a "pbs_attach" prefixed to the executable. The actual mpirun to call is found by tracing the link pointed to by $PBS_EXEC/lib/MPI/pbsrun.<mpirun version/flavor>.link.

For all of the wrapped MPIs, the maximum number of ranks that can be launched is the number of entries in $PBS_NODEFILE.

The wrapped MPIs are:

- MPICH-GM's mpirun (mpirun.ch_gm) with rsh/ssh (The wrapper is **deprecated** as of 14.2.1)
- MPICH-MX's mpirun (mpirun.ch_mx) with rsh/ssh (The wrapper is **deprecated** as of 14.2.1)
- MPICH-GM's mpirun (mpirun.mpd) with MPD (The wrapper is **deprecated** as of 14.2.1)
- MPICH-MX's mpirun (mpirun.mpd) with MPD (The wrapper is **deprecated** as of 14.2.1)
- MPICH2's mpirun
- Intel MPI's mpirun (The wrapper is **deprecated** as of 13.0)
- MVAPICH1's mpirun (The wrapper is **deprecated** as of 14.2.1)
- MVAPICH2's mpiexec

2.8.3 Options

--version

The pbsrun command returns its PBS version information and exits. This option can only be used alone.

2.8.4 Initialization Script

The initialization script, called $PBS_EXEC/lib/MPI/pbsrun.<mpirun version/flavor>.init, where *mpirun version/flavor* reflects the mpirun flavor/version being wrapped, can be modified by an administrator to customize against the local flavor/version of mpirun being wrapped.

Inside this sourced init script, 8 variables are set:

```
options_to_retain="-optA -optB <val> -optC <val1> val2> ..."
options_to_ignore="-optD -optE <n> -optF <val1> val2> ..."
options_to_transform="-optG -optH <val> -optI <val1> val2> ..."
options_to_fail="-optY -optZ ..."
options_to_configfile="-optX <val> ..."
options_with_another_form="-optW <val> ..."
pbs_attach=pbs_attach
options_to_pbs_attach="-J $PBS_JOBID"
```

2.8.4.1 Initialization Script Options

options_to_retain

Space-separated list of options and values that pbsrun.<mpirun version/flavor> passes on to the actual mpirun call. Options must begin with "-" or "--", and option arguments must be specified by some arbitrary name with left and right arrows, as in "<val1>".

options_to_ignore

Space-separated list of options and values that pbsrun.<mpirun version/flavor> does not pass on to the actual mpirun call. Options must begin with "-" or "--", and option arguments must be specified by arbitrary names with left and right arrows, as in "<n>".

options_to_transform

Space-separated list of options and values that pbsrun modifies before passing on to the actual mpirun call.

options_to_fail

Space-separated list of options that will cause pbsrun to exit upon encountering a match.

options_to_configfile

Single option and value that refers to the name of the configuration file containing command line segments found in certain versions of mpirun.

options_with_another_form

Space-separated list of options and values that can be found in *options_to_retain*, *options_to_ignore*, or *options_to_transform*, whose syntax has an alternate, unsupported form.

pbs_attach

Path to pbs_attach, which is called before the *executable* argument of mpirun.

options_to_pbs_attach

Special options to pass to the pbs_attach call. You may pass variable references (e.g. *$PBS_JOBID*) and they are substituted by pbsrun to actual values.

If pbsrun encounters any option not found in *options_to_retain*, *options_to_ignore*, and *options_to_transform*, it is flagged as an error.

These functions are created inside the init script. These can be modified by the PBS administrator.

```
transform_action () {
# passed actual values of $options_to_transform
args=$*
}

boot_action () {
mpirun_location=$1
}

evaluate_options_action () {
# passed actual values of transformed options
args=$*
}

configfile_cmdline_action () {
args=$*
}

end_action () {
mpirun_location=$1
}
```

transform_action()

The pbsrun.<mpirun version/flavor> wrapper script invokes the function transform_action() (called once on each matched item and value) with actual options and values received matching one of the *options_to_transform*. The function returns a string to pass on to the actual mpirun call.

boot_action()

Performs any initialization tasks needed before running the actual mpirun call. For instance, GM's MPD requires the MPD daemons to be user-started first. This function is called by the pbsrun.<mpirun version/flavor> script with the location of actual mpirun passed as the first argument. Also, the pbsrun.<mpirun version/flavor> checks for the exit value of this function to determine whether or not to progress to the next step.

evaluate_options_action()

Called with the actual options and values that resulted after consulting *options_to_retain*, *options_to_ignore*, *options_to_transform*, and executing transform_action(). This provides one more chance for the script writer to evaluate all the options and values in general, and make any necessary adjustments, before passing them on to the actual mpirun call. For instance, this function can specify what the default value is for a missing -np option.

configfile_cmdline_action()

Returns the actual options and values to be put in before the *option_to_configfile* parameter.

configfile_firstline_action()

Returns the item that is put in the first line of the configuration file specified in the *option_to_configfile* parameter.

end_action()

Called by `pbsrun.<mpirun version/flavor>` at the end of execution. It undoes any action done by transform_action(), such as cleanup of temporary files. It is also called when `pbsrun.<mpirun version/flavor>` is prematurely killed. This function is called with the location of actual `mpirun` passed as first argument.

The actual `mpirun` program to call is the path pointed to by `$PBS_EXEC/lib/MPI/pbsrun.<mpirun version/flavor>.link`.

2.8.4.2 Modifying *.init Scripts

In order for administrators to modify `*.init` scripts without breaking package verification in RPM, master copies of the initialization scripts are named `*.init.in`. `pbsrun_wrap` instantiates the `*.init.in` files as `*.init`. For instance, `$PBS_EXEC/lib/MPI/pbsrun.mpich2.init.in` is the master copy, and `pbsrun_wrap` instantiates it as `$PBS_EXEC/lib/MPI/pbsrun.mpich2.init`. `pbsrun_unwrap` takes care of removing the `*.init` files.

2.8.5 Versions/Flavors of `mpirun`

2.8.5.1 MPICH-GM `mpirun` (`mpirun.ch_gm`) with `rsh/ssh`: `pbsrun.ch_gm`

2.8.5.1.i Syntax

pbsrun.ch_gm <options> <executable> <arg1> <arg2> ... <argn>

Deprecated. The PBS wrapper script to MPICH-GM's `mpirun` (`mpirun.ch_gm`) with `rsh/ssh` process startup method is named `pbsrun.ch_gm`.

If executed inside a PBS job, this allows for PBS to track all MPICH-GM processes started by `rsh/ssh` so that PBS can perform accounting and have complete job control.

If executed outside of a PBS job, it behaves exactly as if standard `mpirun.ch_gm` were used.

2.8.5.1.ii Options Handling

If executed inside a PBS job script, all `mpirun.ch_gm` options given are passed on to the actual `mpirun` call with these exceptions:

-machinefile <file>

The *file* argument contents are ignored and replaced by the contents of $PBS_NODEFILE.

-np

If not specified, the number of entries found in $PBS_NODEFILE is used.

-pg

The use of the `-pg` option, for having multiple executables on multiple hosts, is allowed but it is up to the user to make sure only PBS hosts are specified in the process group file; MPI processes spawned are not guaranteed to be under the control of PBS.

2.8.5.1.iii Wrap/Unwrap

To wrap MPICH-GM's `mpirun` script:

```
# pbsrun_wrap [MPICH-GM_BIN_PATH]/mpirun.ch_gm pbsrun.ch_gm
```

To unwrap MPICH-GM's `mpirun` script:

```
# pbsrun_unwrap pbsrun.ch_gm
```

2.8.5.2 MPICH-MX `mpirun` (`mpirun.ch_mx`) with `rsh/ssh`: `pbsrun.ch_mx`

2.8.5.2.i Syntax

pbsrun.ch_mx <options> <executable> <arg1> <arg2> ... <argn>

The wrapper is **deprecated**. The PBS wrapper script to MPICH-MX's `mpirun` (`mpirun.ch_gm`) with `rsh/ssh` process startup method is named `pbsrun.ch_mx`.

If executed inside a PBS job, this allows PBS to track all MPICH-MX processes started by `rsh/ssh` so that PBS can perform accounting and have complete job control.

If executed outside of a PBS job, it behaves exactly as if standard `mpirun.ch_mx` were used.

2.8.5.2.ii Options Handling

If executed inside a PBS job script, all `mpirun.ch_gm` options given are passed on to the actual `mpirun` call with some exceptions:

-machinefile <file>

The *file* argument contents is ignored and replaced by the contents of $PBS_NODEFILE.

-np

If not specified, the number of entries found in $PBS_NODEFILE is used.

-pg

The use of the -pg option, for having multiple executables on multiple hosts, is allowed but it is up to the user to make sure only PBS hosts are specified in the process group file; MPI processes spawned are not guaranteed to be under the control of PBS.

2.8.5.2.iii Wrap/Unwrap

To wrap MPICH-MX's `mpirun` script:

```
# pbsrun_wrap [MPICH-MX_BIN_PATH]/mpirun.ch_mx pbsrun.ch_mx
```

To unwrap MPICH-MX's `mpirun` script:

```
# pbsrun_unwrap pbsrun.ch_mx
```

2.8.5.3 MPICH-GM `mpirun` (`mpirun.mpd`) with MPD: `pbsrun.gm_mpd`

2.8.5.3.i Syntax

pbsrun.gm_mpd <options> <executable> <arg1> <arg2> ... <argn>

The wrapper is **deprecated**. The PBS wrapper script to MPICH-GM's `mpirun` (`mpirun.ch_gm`) with MPD process startup method is called `pbsrun.gm_mpd`.

If executed inside a PBS job, this allows PBS to track all MPICH-GM processes started by the MPD daemons so that PBS can perform accounting and have complete job control.

If executed outside of a PBS job, it behaves exactly as if standard `mpirun.ch_gm` with MPD were used.

2.8.5.3.ii Options Handling

If executed inside a PBS job script, all `mpirun.ch_gm` with MPD options given are passed on to the actual `mpirun` call with these exceptions:

-m <file>

The *file* argument contents are ignored and replaced by the contents of $PBS_NODEFILE.

-np

If not specified, the number of entries found in $PBS_NODEFILE is used.

-pg

The use of the -pg option, for having multiple executables on multiple hosts, is allowed but it is up to the user to make sure only PBS hosts are specified in the process group file; MPI processes spawned are not guaranteed to be under the control of PBS.

2.8.5.3.iii Startup/Shutdown

The script starts MPD daemons on each of the unique hosts listed in $PBS_NODEFILE, using either `rsh` or `ssh` based on the value of the environment variable RSHCOMMAND. The default is `rsh`.

The script also takes care of shutting down the MPD daemons at the end of a run.

2.8.5.3.iv Wrap/Unwrap

To wrap MPICH-GM's `mpirun` script with MPD:

```
# pbsrun_wrap [MPICH-GM_BIN_PATH]/mpirun.mpd pbsrun.gm_mpd
```

To unwrap MPICH-GM's `mpirun` script with MPD:

```
# pbsrun_unwrap pbsrun.gm_mpd
```

2.8.5.4 MPICH-MX `mpirun` (`mpirun.mpd`) with MPD: `pbsrun.mx_mpd`

2.8.5.4.i Syntax

pbsrun.mx_mpd <options> <executable> <arg1> <arg2> ... <argn>

The wrapper is **deprecated**. The PBS wrapper script to MPICH-MX's `mpirun` (`mpirun.ch_mx`) with MPD process startup method is called `pbsrun.mx_mpd`.

If executed inside a PBS job, this allows PBS to track all MPICH-MX processes started by the MPD daemons so that PBS can perform accounting and have complete job control.

If executed outside of a PBS job, it behaves exactly as if standard `mpirun.ch_mx` with MPD were used.

2.8.5.4.ii Options Handling

If executed inside a PBS job script, all `mpirun.mx_mpd` with MPD options given are passed on to the actual `mpirun` call with these exceptions:

-m <file>

The *file* argument contents are ignored and replaced by the contents of $PBS_NODEFILE.

-np

If not specified, the number of entries found in $PBS_NODEFILE is used.

-pg

The use of the -pg option, for having multiple executables on multiple hosts, is allowed but it is up to the user to make sure only PBS hosts are specified in the process group file; MPI processes spawned are not guaranteed to be under the control of PBS.

2.8.5.4.iii Startup/Shutdown

The script starts MPD daemons on each of the unique hosts listed in $PBS_NODEFILE, using either `rsh` or `ssh` , based on the value of the environment variable RSHCOMMAND. The default is `rsh`.

The script also takes care of shutting down the MPD daemons at the end of a run.

2.8.5.4.iv Wrap/Unwrap

To wrap MPICH-MX's `mpirun` script with MPD:

```
# pbsrun_wrap [MPICH-MX_BIN_PATH]/mpirun.mpd pbsrun.mx_mpd
```

To unwrap MPICH-MX's `mpirun` script with MPD:

```
# pbsrun_unwrap pbsrun.mx_mpd
```

2.8.5.5 MPICH2 `mpirun`: `pbsrun.mpich2`

2.8.5.5.i Syntax

pbsrun.mpich2 [<global args>] [<local args>] <executable> [<args>] [: [<local args>] <executable> [<args>]]

- or -

pbsrun.mpich2 -configfile <configfile>

where *configfile* contains command line segments as lines:

```
[local args] executable1 [args]
[local args] executable2 [args]
[local args] executable3 [args]
```

The PBS wrapper script to MPICH2's `mpirun` is called `pbsrun.mpich2`.

If executed inside a PBS job, this allows PBS to track all MPICH2 processes so that PBS can perform accounting and have complete job control.

If executed outside of a PBS job, it behaves exactly as if standard MPICH2's `mpirun` were used.

2.8.5.5.ii Options Handling

If executed inside a PBS job script, all MPICH2's `mpirun` options given are passed on to the actual `mpirun` call with these exceptions:

-host and -ghost

For specifying the execution host to run on. Not passed on to the actual `mpirun` call.

-machinefile <file>

The *file* argument contents are ignored and replaced by the contents of $PBS_NODEFILE.

MPICH2's mpirun -localonly <num processes>

For specifying number of processes to run locally. Not supported. The user is advised instead to use the equivalent arguments: `-np <num processes> -localonly`. The reason for this is that the `pbsrun` wrapper script cannot handle a variable number of arguments to an option (e.g. "`-localonly`" has one argument and "`-localonly <num processes>`" has two arguments).

-np

If the user does not specify the `-np` option, no default value is provided by the PBS wrapper scripts. It is up to the local `mpirun` to decide what the reasonable default value should be, which is usually *1*.

2.8.5.5.iii Startup/Shutdown

The script takes care of ensuring that the MPD daemons on each of the hosts listed in $PBS_NODEFILE are started. It also takes care of ensuring that the MPD daemons have been shut down at the end of MPI job execution.

2.8.5.5.iv Wrap/Unwrap

To wrap MPICH2's `mpirun` script:

```
# pbsrun_wrap [<MPICH2 BIN PATH>]/mpirun pbsrun.mpich2
```

To unwrap MPICH2's `mpirun` script:

```
# pbsrun_unwrap pbsrun.mpich2
```

In the case where MPICH2 uses `mpirun.py`, run `pbsrun_wrap` on `mpirun.py` itself.

2.8.5.6 Intel MPI `mpirun`: `pbsrun.intelmpi`

Wrapping Intel MPI, and support for `mpdboot`, are **deprecated**.

2.8.5.6.i Syntax

pbsrun.intelmpi [<mpdboot options>] [<mpiexec options>] <executable> [<prog args>] [: [<mpiexec options>] <executable> [<prog args>]]

- or -

pbsrun.intelmpi [<mpdboot options>] -f <configfile>

where *mpdboot options* are any options to pass to the `mpdboot` program, which is automatically called by Intel MPI's `mpirun` to start MPDs, and *configfile* contains command line segments as lines.

The PBS wrapper script to Intel MPI's `mpirun` is called `pbsrun.intelmpi`.

If executed inside a PBS job, this allows PBS to track all Intel MPI processes so that PBS can perform accounting and have complete job control.

If executed outside of a PBS job, it behaves exactly as if standard Intel MPI's `mpirun` were used.

2.8.5.6.ii Options Handling

If executed inside a PBS job script, all of the options to the PBS interface to Intel MPI's `mpirun` are passed to the actual `mpirun` call with these exceptions:

-host and -ghost
: For specifying the execution host to run on. Not passed on to the actual `mpirun` call.

-machinefile <file>
: The *file* argument contents are ignored and replaced by the contents of $PBS_NODEFILE.

mpdboot options --totalnum=* and --file=*
: Ignored and replaced by the number of unique entries in $PBS_NODEFILE and name of $PBS_NODEFILE respectively.

arguments to mpdboot options --file=* and -f <mpd_hosts_file>
: Replaced by $PBS_NODEFILE.

-s
: If `pbsrun.intelmpi` is called inside a PBS job, Intel MPI's `mpirun -s` argument to `mpdboot` is not supported as this closely matches the `mpirun` option `-s <spec>`. The user can simply run a separate `mpdboot -s` before calling `mpirun`. A warning message is issued by `pbsrun.intelmpi` upon encountering a `-s` option telling users of the supported form.

-np

If the user does not specify the -np option, no default value is provided by the PBS wrap scripts. It is up to the local mpirun to decide what the reasonable default value should be, which is usually *1*.

2.8.5.6.iii Startup/Shutdown

Intel MPI's mpirun itself takes care of starting/stopping the MPD daemons. pbsrun.intelmpi always passes the arguments -totalnum=<number of mpds to start> and -file=<mpd_hosts_file> to the actual mpirun, taking its input from unique entries in $PBS_NODEFILE.

2.8.5.6.iv Wrap/Unwrap

To wrap Intel MPI's mpirun script:

```
# pbsrun_wrap [INTEL_MPI_BIN_PATH]/mpirun pbsrun.intelmpi
```

To unwrap Intel MPI's mpirun script:

```
# pbsrun_unwrap pbsrun.intelmpi
```

2.8.5.7 MVAPICH1 mpirun: pbsrun.mvapich1

2.8.5.7.i Syntax

pbsrun.mvapich1 <mpirun options> <executable> <options>

The wrapper is **deprecated**. The PBS wrapper script to MVAPICH1's mpirun is called pbsrun.mvapich1.

Only one executable can be specified. MVAPICH1 allows the use of InfiniBand.

If executed inside a PBS job, this allows PBS to be aware of all MVAPICH1 ranks and to track their resources, so that PBS can perform accounting and have complete job control.

If executed outside of a PBS job, it behaves exactly as if standard mpirun were used.

2.8.5.7.ii Options Handling

If executed inside a PBS job script, all mpirun options given are passed on to the actual mpirun call with these exceptions:

-map <list>

The map option is ignored.

-exclude <list>

The exclude option is ignored.

-machinefile <file>

The machinefile option is ignored.

-np

If not specified, the number of entries found in $PBS_NODEFILE is used.

2.8.5.7.iii Wrap/Unwrap

To wrap MVAPICH1's mpirun script:

```
# pbsrun_wrap <path-to-actual-mpirun> pbsrun.mvapich1
```

To unwrap MVAPICH1's mpirun script:

```
# pbsrun_unwrap pbsrun.mvapich1
```

2.8.5.8 MVAPICH2 `mpiexec: pbsrun.mvapich2`

2.8.5.8.i Syntax

pbsrun.mvapich2 <mpiexec args> <executable> <executable's args> [: <mpiexec args> <executable> <executable's args>]

The PBS wrapper script to MVAPICH2's `mpiexec` is called `pbsrun.mvapich2`.

Multiple executables can be specified using the colon notation. MVAPICH2 allows the use of InfiniBand.

If executed inside a PBS job, this allows PBS to be aware of all MVAPICH2 ranks and to track their resources, so that PBS can perform accounting and have complete job control.

If executed outside of a PBS job, it behaves exactly as if standard `mpiexec` were used.

2.8.5.8.ii Options Handling

If executed inside a PBS job script, all `mpiexec` options given are passed on to the actual `mpiexec` call with these exceptions:

-host <hostname>

The *hostname* argument contents are ignored.

-machinefile <file>

The *file* argument contents are ignored and replaced by the contents of the $PBS_NODEFILE.

2.8.5.8.iii Wrap/Unwrap

To wrap MVAPICH2's `mpiexec` script:

```
# pbsrun_wrap <path-to-actual-mpiexec> pbsrun.mvapich2
```

To unwrap MVAPICH2's `mpiexec` script:

```
# pbsrun_unwrap pbsrun.mvapich2
```

2.8.6 Requirements

The `mpirun` being wrapped must be installed and working on all the vnodes in the PBS cluster.

2.8.7 Errors

If `pbsrun` encounters any option not found in *options_to_retain*, *options_to_ignore*, and *options_to_transform*, it is flagged as an error.

2.8.8 See Also

The PBS Professional Administrator's Guide, "pbs_attach" on page 56, "pbsrun_wrap" on page 52, "pbsrun_unwrap" on page 51

2.9 pbsrun_unwrap

Unwraps `mpirun`, reversing `pbsrun_wrap`

2.9.1 Synopsis

pbsrun_unwrap pbsrun.<mpirun version/flavor>

pbsrun_unwrap --version

2.9.2 Description

The `pbsrun_unwrap` script is used to reverse the actions of the `pbsrun_wrap` script.

Use `pbsrun_wrap` to wrap `mpirun`.

Using `pbsrun_unwrap` for Intel MPI is **deprecated** as of 13.0.

2.9.2.1 Syntax

pbsrun_unwrap pbsrun.<mpirun version/flavor>

For example, running the following:

```
pbsrun_unwrap pbsrun.ch_gm
```

causes the following actions:

1. Checks for a link in `$PBS_EXEC/lib/MPI/pbsrun.ch_gm.link`; If one exists, get the pathname it points to, for example:

   ```
   /opt/mpich-gm/bin/mpirun.ch_gm.actual
   ```

2. rm $PBS_EXEC/lib/MPI/pbsrun.mpirun.ch_gm.link
3. rm /opt/mpich-gm/bin/mpirun.ch_gm
4. rm $PBS_EXEC/bin/pbsrun.ch_gm
5. mv /opt/mpich-gm/bin/mpirun.ch_gm.actual /opt/mpich-gm/bin/mpirun.ch_gm

2.9.3 Options

--version

The `pbsrun_unwrap` command returns its PBS version information and exits. This option can only be used alone.

2.9.4 See Also

The PBS Professional Administrator's Guide,"pbs_attach" on page 56, "pbsrun_wrap" on page 52

2.10 pbsrun_wrap

General-purpose script for wrapping mpirun in pbsrun

2.10.1 Synopsis

pbsrun_wrap [-s] <path to actual mpirun> pbsrun.<mpirun version/flavor>

pbsrun_wrap --version

2.10.2 Description

The pbsrun_wrap script is used to wrap any of several versions of mpirun in pbsrun. The pbsrun_wrap script creates a symbolic link with the same path and name as the mpirun being wrapped. This calls pbsrun, which uses pbs_attach to give MoM control of jobs. The result is transparent to the user; when mpirun is called from inside a PBS job, PBS can monitor and control the job, but when mpirun is called from outside of a PBS job, it behaves as it would normally. See "pbs_attach" on page 56.

Use pbsrun_unwrap to reverse the process.

Using pbsrun_wrap for Intel MPI is **deprecated** as of 13.0.

Available only under Linux.

2.10.2.1 Syntax

pbsrun_wrap [-s] <path to actual mpirun> pbsrun.<mpirun version/flavor>

Any mpirun version/flavor that can be wrapped has an initialization script ending in ".init", found in $PBS_EXEC/lib/MPI:

```
$PBS_EXEC/lib/MPI/pbsrun.<mpirun version/flavor>.init
```

The pbsrun_wrap script instantiates the pbsrun wrapper script as pbsrun.<mpirun version/flavor> in the same directory where pbsrun is located, and sets up the link to actual mpirun call via the symbolic link:

```
$PBS_EXEC/lib/MPI/pbsrun.<mpirun version/flavor>.link
```

For example, running:

```
pbsrun_wrap /opt/mpich-gm/bin/mpirun.ch_gm pbsrun.ch_gm
```

causes the following actions:

1. Save original mpirun.ch_gm script:
   mv /opt/mpich-gm/bin/mpirun.ch_gm /opt/mpich/gm/bin/mpirun.ch_gm.actual
2. Instantiate pbsrun wrapper script as pbsrun.ch_gm:
   cp $PBS_EXEC/bin/pbsrun $PBS_EXEC/bin/pbsrun.ch_gm
3. Link "mpirun.ch_gm" to actually call "pbsrun.ch_gm":
   ln -s $PBS_EXEC/bin/pbsrun.ch_gm /opt/mpich-gm/bin/mpirun.ch_gm
4. Create a link so that "pbsrun.ch_gm" calls "mpirun.ch_gm.actual":
   ln -s /opt/mpich-gm/bin/mpirun.ch_gm.actual $PBS_EXEC/lib/MPI/pbsrun.ch_gm.link

2.10.3 Options

-s

Sets the "strict_pbs" options in the various initialization scripts (e.g. pbsrun.bgl.init, pbsrun.ch_gm.init, etc...) to *1* from the default *0*. This means that the mpirun being wrapped by pbsrun will only be executed if inside a PBS environment. Otherwise, the user gets the error:

```
Not running under PBS exiting since strict_pbs is enabled; execute only in PBS
```

--version

The pbsrun_wrap command returns its PBS version information and exits. This option can only be used alone.

2.10.4 Requirements

The mpirun being wrapped must be installed and working on all the vnodes in the PBS complex.

2.10.5 See Also

The PBS Professional Administrator's Guide, "pbs_attach" on page 56, "pbsrun_unwrap" on page 51

2.11 pbs_account

For Windows. Manage PBS service account

2.11.1 Synopsis

pbs_account [-a <PBS service account name>] [-c [<password>]] [--ci] [--instid <instance ID>] [-o <output path>] [-p [<password>]] [--reg <service path>] [-s] [--unreg <service path>]

2.11.2 Description

The `pbs_account` command is used to manage the PBS service account. It is used to create the account, set or validate the account password, add privileges to the account, and register or unregister the account with the SCM.

2.11.2.1 Permissions

This command can be run by administrators only.

2.11.2.2 Platforms

This command is available on Windows only.

2.11.2.3 Caveats

Using `pbs_account --unreg` and `pbs_account --reg` stops and restarts MoM, which can kill jobs.

2.11.3 Options

-a <account name>

Specifies service account name.

-c [<password>]

- If specified account does not exist, creates the account with the password.
- If specified account exists, validates password against it.

Gives necessary privileges to the specified account: *Create Token Object*, *Replace Process Level Token*, *Log on as a Service*, and *Act as Part of the Operating System*

If password is not specified, user is prompted for password.

--ci

Informational only. Prints actions taken by `pbs_account` while creating PBS service account when operations are performed.

--instid <instance ID>

Specifies the instance ID when registering or unregistering multiple instances of a service. Example:

```
pbs_account --reg "C:\Program Files (x86)\PBS Pro_2\exec\sbin\pbs_mom" --instid 2 -a <username>
    -p <password>

pbs_account --unreg "C:\Program Files (x86)\PBS Pro_2\exec\sbin\pbs_mom" --instid 2
```

-o <output path>

Prints `stdout` and `stderr` messages in specified output path.

-p [<password >]

Updates the PBS service account password. If no password is specified, the user is prompted for a password.

--reg <path to service>

Registers the PBS service with the SCM, instructing it to run the services under the PBS service account. *path to service* must be in double quotes. Restarts MoM.

-s

Adds necessary privileges to the PBS service account. Grants the "Create Token Object", "Replace Process Level Token", "Log On as a Service", and "Act as Part of the Operating System" privileges to PBS service account.

--unreg <path to service>

Unregisters the PBS service with the SCM. *path to service* must be in double quotes. Stops MoM.

(no options)

Prints name of PBS service account, if it exists. Exit value is 0.

2.11.4 Examples

Example 2-1: To create the PBS service account:

```
pbs_account -c -s -p <password>
```

Example 2-2: To change the PBS service account:

```
pbs_account --reg <service path> -a <PBS service account name>
```

Example 2-3: To register the MoM service:

```
pbs_account --reg "\Program Files\PBS\exec\sbin\pbs_mom.exe" -p <password>
```

2.11.5 Exit Value

Zero

Upon success

2.12 pbs_attach

Attaches a session ID to a PBS job

2.12.1 Synopsis

Linux

pbs_attach [-j <job ID>] [-m <port number>] -p <PID>

pbs_attach [-j <job ID>] [-m <port number>] [-P] [-s] <cmd> [<arg> ...]

pbs_attach --version

Windows

pbs_attach [-c <path to script>] [-j <job ID>] [-m <port number>] -p <PID>

pbs_attach [-c <path to script>] [-j <job ID>] [-m <port number>] [-P] [-s] <cmd> [<arg> ...]

pbs_attach --version

2.12.2 Description

The `pbs_attach` command associates the processes in a session with a PBS job by attaching the session ID to the job. This allows PBS MoM to monitor and control those processes.

MoM uses process IDs to determine session IDs, which are put into MoM's task list (attached to the job.) All process IDs in a session are then associated with the job.

When a command *cmd* is given as an operand, the `pbs_attach` process becomes the parent process of *cmd*, and the session ID of `pbs_attach` is attached to the job.

2.12.3 Options to `pbs_attach`

-c <path to script>

Windows only. Specified command is invoked using a new command shell. In order to spawn and attach built-in DOS commands such as `set` or `echo`, it is necessary to open the task using a `cmd` shell. The new command shell, `cmd.exe`, is attached as a task to the PBS job. The `pbs_attach` command spawns a program using a new command shell when attaching a batch script, or when invoked with the `-c` option.

-j <job ID>

The job ID to which the session ID is to be attached. If *job ID* is not specified, a best effort is made to determine the job to which to attach the session.

-m <port number>

The port at which to contact MoM. Default: value of $PBS_MANAGER_SERVICE_PORT from `pbs.conf`.

-p <PID>

Process ID whose session ID is to be attached to the job. Default: process ID of `pbs_attach`. Cannot be used with the `-P` or `-s` options or the *cmd* operand.

-P

Attach sessions of both `pbs_attach` and the parent of `pbs_attach` to job. When used with `-s` option, the sessions of the new `fork()`ed `pbs_attach` and its parent, which is `pbs_attach`, are attached to the job. Cannot be used with the `-p` or `-s` options or the *cmd* operand.

-s

Starts a new session and attaches it to the job; `pbs_attach` calls `fork()`, then the child `pbs_attach` first calls `setsid()` and then calls `tm_attach` to attach the new session to the job. The session ID of the new `pbs_attach` is attached to the job.

--version

The `pbs_attach` command returns its PBS version information and exits. This option can only be used alone.

2.12.4 Operands

cmd

Name of command whose process ID is to be associated with the job.

2.12.5 Exit Status

0

Success

1

Any error following successful command line processing. A message is printed to standard error.

If *cmd* is specified, `pbs_attach` waits for *cmd* to exit, then exits with the exit value of *cmd*.

If *cmd* is not specified, `pbs_attach` exits after attaching the session ID(s) to the job.

The PBS Professional Administrator's Guide, "pbs_mom" on page 71, "pbs_tmrsh" on page 123, "TM Library", on page 95 of the PBS Professional Programmer's Guide

2.13 pbs_comm

Starts the PBS communication daemon

2.13.1 Synopsis

pbs_comm [-N] [-r <other routers>] [-t <number of threads>]

pbs_comm --version

2.13.2 Description

The PBS communication daemon, `pbs_comm`, handles communication between daemons, except for scheduler-server and server-server communication, which uses TCP. The server, scheduler(s), and MoMs are connected by one or more `pbs_comm` daemons.

See "Communication" on page 45 in the PBS Professional Installation & Upgrade Guide.

Available on Linux only.

2.13.3 Options to pbs_comm

-N

Runs the communication daemon in standalone mode.

-r <other routers>

List of other `pbs_comm` daemons to which this `pbs_comm` must connect. This is equivalent to the `pbs.conf` variable PBS_COMM_ROUTERS. The command line overrides the variable. Format:

<hostname>[:<port number>][,<hostname>[:<port number>]]

-t <number of threads>

Number of threads the `pbs_comm` daemon uses. This is equivalent to the `pbs.conf` variable PBS_COMM_THREADS. The command line overrides the variable. Format:

Integer

--version

Prints the PBS version information and exits. This option can only be used alone.

2.13.4 Configuration Parameters

PBS_LEAF_ROUTERS

Parameter in `/etc/pbs.conf`. Tells an endpoint where to find its communication daemon.

You can tell each endpoint which communication daemon it should talk to. Specifying the port is optional.

Format: *PBS_LEAF_ROUTERS=<hostname>[:<port number>][,<hostname>[:<port number>]]*

PBS_COMM_ROUTERS

Parameter in `/etc/pbs.conf`. Tells a `pbs_comm` where to find its fellow communication daemons.

When you add a communication daemon, you must tell it about the other `pbs_comm`s in the complex. When you inform communication daemons about each other, you only tell one of each pair about the other. Do not tell both about each other. We recommend that an easy way to do this is to tell each new `pbs_comm` about each existing `pbs_comm`, and leave it at that.

Format: *PBS_COMM_ROUTERS=<hostname>[:<port number>][,<hostname>[:<port number>]]*

PBS_COMM_THREADS

Parameter in `/etc/pbs.conf`. Tells `pbs_comm` how many threads to start.

By default, each `pbs_comm` process starts four threads. You can configure the number of threads that each `pbs_comm` uses. Usually, you want no more threads than the number of processors on the host.

Maximum allowed value: *100*

Format: *Integer*

Example:

```
PBS_COMM_THREADS=8
```

PBS_COMM_LOG_EVENTS

Parameter in `/etc/pbs.conf`. Tells `pbs_comm` which log mask to use.

By default, `pbs_comm` produces few log messages. You can choose more logging, usually for troubleshooting. See "Logging and Errors with TPP" on page 54 in the PBS Professional Installation & Upgrade Guide for logging details.

Format: *Integer*

Default: *511*

Example:

```
PBS_COMM_LOG_EVENTS=<log level>
```

PBS_LEAF_NAME

Parameter in `/etc/pbs.conf`. Tells endpoint what name to use for network. The value does not include a port, since that is usually set by the daemon.

By default, the name of the endpoint's host is the hostname of the machine. You can set the name where an endpoint runs. This is useful when you have multiple networks configured, and you want PBS to use a particular network.

The server only queries for the canonicalized address of the MoM host, unless you let it know via the Mom attribute; if you have set PBS_LEAF_NAME in `/etc/pbs.conf` to something else, make sure you set the Mom attribute at vnode creation.

TPP internally resolves the name to a set of IP addresses, so you do not affect how `pbs_comm` works.

Format: *String*

Example:

```
PBS_LEAF_NAME=host1
```

PBS_START_COMM

Parameter in `/etc/pbs.conf`. Tells PBS init script whether to start a `pbs_comm` on this host if one is installed. When set to *1*, `pbs_comm` is started.

Just as with the other PBS daemons, you can specify whether each host should start `pbs_comm`.

Format: *Boolean*

Default: *0*

Example:

```
PBS_START_COMM=1
```

2.13.5 Communication Daemon Logfiles

The `pbs_comm` daemon creates its log files under `$PBS_HOME/comm_logs`. This directory is automatically created by the PBS installer.

In a failover configuration, this directory is in the shared PBS_HOME, and is used by the pbs_comm daemons running on both the primary and secondary servers. This directory must never be shared across multiple pbs_comm daemons in any other case.

The log filename format is *yyyymmdd* (the same as for other PBS daemons).

The log record format is the same as used by other pbs daemons, with the addition of the thread number and the daemon name in the log record. The log record format is as follows:

<date and time>;<event code>;<daemon name>(<thread number>);<object type>;<object name>;<message>

Example:

```
03/25/2014 15:13:39;0d86;host1.example.com;TPP;host1.example.com(Thread 2);Connection from leaf
    192.168.184.156:19331, tfd=81 down
```

2.13.6 Signal Handling by Communication Daemon

The pbs_comm daemon handles the following signals:

HUP

Re-reads the value of $PBS_COMM_LOG_EVENTS from pbs.conf.

TERM

The pbs_comm daemon exits.

2.14 pbs_dataservice

Start, stop, or check the status of PBS data service

2.14.1 Synopsis

pbs_dataservice [start | stop | status]

2.14.2 Description

The `pbs_dataservice` command starts, stops or gets the status of the PBS data service.

2.14.2.1 Permission

Root privilege is required to use this command.

2.14.3 Arguments

start
: Starts the PBS data service.

stop
: Stops the PBS data service.

  Can be used only when the PBS server is not running.

status
: Displays the status of the PBS data service, as follows:

  - Data service running

    `PBS Data Service running`
  - Data service not running

    `PBS Data Service not running`

2.14.4 Exit Status

Zero
: Success

Non-zero
: Failure

2.15 pbs_ds_password

Sets or changes data service user account or its password

2.15.1 Synopsis

pbs_ds_password [-C <username>] [-r]

2.15.2 Description

You can use this command to change the user account or account password for the data service.

2.15.2.1 Passwords

Blank passwords are not allowed.

If you type in a password, make sure it does not contain restricted characters. The `pbs_ds_password` command generates passwords containing the following characters:

0123456789abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ!@#$%^&()_+*

When creating a password manually, do not use \ (backslash) or ‘ (backquote). This can prevent certain commands such as `pbs_server`, `pbs_ds_password`, and `printjob` from functioning properly, as they rely on connecting to the database. The format is also described in "PBS Password" on page 357.

2.15.2.2 Permissions

On Linux, root privilege is required to use this command. On Windows, Admin privilege is required.

2.15.2.3 Restrictions

Do not run this command if failover is configured. It is important not to inadvertently start two separate instances of the data service on two machines, thus potentially corrupting the database. If failover is configured, stop the secondary server, remove definitions for PBS_PRIMARY and PBS_SECONDARY from `pbs.conf` on the primary server host, start PBS, run `pbs_ds_password`, stop PBS, replace the definitions, and start PBS again.

2.15.3 Options to `pbs_ds_password`

-C <username>

Changes user account for data service to specified account. Specified user account must already exist.

On Linux-based systems, the specified user account must not be root.

On Windows, the specified user account must match the PBS service account (which can be any user account.)

This option cannot be used while the data service is running.

Can be used with the `-r` option to automatically generate a password for the new account.

-r

Generates a random password. The data service is updated with the new password.

Can be used with the `-C` option.

(no options)

Asks the user to enter a new password twice. Entries must match. Updates data service with new password.

2.15.4 Exit Status

Zero
: Success

Non-zero
: Failure

2.16 pbs_hostn

Reports hostname and network address(es)

2.16.1 Synopsis

pbs_hostn [-v] <hostname>

pbs_hostn --version

2.16.2 Description

The `pbs_hostn` command takes a hostname, and reports the results of both the `gethostbyname(3)` and `gethostbyaddr(3)` system calls. Both forward and reverse lookup of hostname and network addresses need to succeed in order for PBS to authenticate a host.

Running this command can assist in troubleshooting problems related to incorrect or non-standard network configuration, especially within clusters.

2.16.3 Options

-v
: Turns on verbose mode.

--version
: The `pbs_hostn` command returns its PBS version information and exits. This option can only be used alone.

2.16.4 Operands

hostname
: The `pbs_hostn` command accepts a *hostname* operand either in short name form, or in fully qualified domain name (FQDN) form.

2.16.5 Standard Error

The `pbs_hostn` command writes a diagnostic message to standard error for each error occurrence.

2.16.6 Exit Status

Zero
: Upon successful processing of all the operands presented to the `pbs_hostn` command.

Greater than zero
: If the `pbs_hostn` command fails to process any operand.

2.17 pbs_idled

Runs PBS daemon that monitors the console and informs pbs_mom of idle time

2.17.1 Linux Synopsis

pbs_idled [-D <display>] [-r <reconnect delay>] [-w <wait time>]

pbs_idled --version

2.17.2 Windows Synopsis

pbs_idled [start | stop]

pbs_idled --version

2.17.3 Linux Description

On Linux, the pbs_idled program monitors an X windows display and communicates the idle time of the display back to PBS. If the mouse is moved or a key is touched, PBS is informed that the vnode is busy.

You should run this program from the system-wide Xsession file, in the background before the window manager is run. If this program is run outside of the Xsession, it needs to be able to make a connection to the X display. See the xhost or xauth man pages for a description of X security.

2.17.4 Windows Description

On Windows, pbs_idled reads its polling interval from a file called idle_poll_time which is created by MoM. The service monitors keyboard, mouse, and console activity, and updates a file called idle_touch when it finds user activity. The idle_touch file is created by MoM.

2.17.5 Linux Options to pbs_idled

-D <display>
: The display to connect to and monitor

-r <reconnect delay>
: Time to wait before we try to reconnect to the X display if the previous attempt was unsuccessful

-w <wait time>
: Interval between times when the daemon checks for events or pointer movement

--version
: The pbs_idled command returns its PBS version information and exits. This option can only be used alone.

2.17.6 Windows Options to pbs_idled

start
: Starts the pbs_idled process.

stop

Stops the pbs_idled process.

--version

The pbs_idled process returns its PBS version information and exits. This option can only be used alone.

2.17.7 See Also

The PBS Professional Administrator's Guide

xhost(1), xauth(1)

2.18 pbs_iff

Tests authentication with the server

2.18.1 Usage

pbs_iff [-t] <server host> <server port>

pbs_iff --version

2.18.2 Description

Called from the pbs_connect() IFL API to authenticate a connection with the PBS server. Designed to be called internally by PBS commands and components, to be used by our IFL layer to talk to the server.

If `pbs_iff` cannot authenticate, it returns an error message.

2.18.2.1 Required Privilege

Can be run by any user.

It's a setuid root binary so it runs as the user who requests a connection to a server but it becomes root so that it can grab a privileged port.

2.18.3 Options to pbs_iff

-t
: Test mode; means test whether `pbs_iff` can authenticate with the server

--version
: Reports version and exits; can only be used alone

2.18.4 Arguments to pbs_iff

daemon host
: Host where server is running

daemon port
: Port on which server is listening; default is 15001

2.18.5 Exit Status

Zero
: If `pbs_iff` is able to contact the server at the specified port

Non-zero
: If `pbs_iff` is unable to contact the server at the specified port

2.19 pbs_interactive

Windows. Register, unregister, or get the version of PBS_INTERACTIVE service

2.19.1 Synopsis

pbs_interactive [R | U]

pbs_interactive --version

2.19.2 Description

The pbs_interactive command registers, unregisters, or gets the version of the Windows PBS_INTERACTIVE service. The service must be registered manually; the installer does not register it.

On Windows, the PBS_INTERACTIVE service itself monitors logging in and out by users, starts a pbs_idled process for each user logging in, and stops the pbs_idled process of each user logging out.

2.19.2.1 Required Privilege

Admin privilege is required to use this command.

2.19.3 Arguments

R

Registers the PBS_INTERACTIVE service.

U

Unregisters the PBS_INTERACTIVE service.

--version

The pbs_interactive command returns its PBS version information and exits. This option can only be used alone.

2.20 pbs_login

Caches encrypted user password for authentication

2.20.1 Usage

pbs_login

pbs_login -m <PBS service account password>

echo <password>| pbs_login -p

2.20.2 Description

The `pbs_login` command encrypts the password and caches it locally where it can be used by daemons for authorization.

Job submitters must run this command at each submission host each time their password changes.

On Windows, the `win_postinstall` script calls `pbs_login` to store the PBS service account password so that the account user can be authenticated by daemons.

2.20.3 Required Privilege

Can be run by any user.

2.20.4 Options to pbs_login

(no options)

Queries user for password.

-m <PBS service account password>

This option is intended to be used only by the PBS service account, which is the account that is used to execute `pbs_mom` via the Service Control Manager on Windows. This option is used during installation when invoked by the `win_postinstall` script, or by the administrator when the PBS service account password has changed. Stores PBS service account password in the `mom_priv` directory.

-p

Caches user password on client host. Intended to be run by job submitter at client host. Allows job submitter to be authenticated by daemons.

2.21 pbs_mkdirs

For Windows. Create, or fix the permissions of, the directories and files used by PBS

2.21.1 Synopsis

pbs_mkdirs

pbs_mkdirs [mom]

2.21.2 Description

Runs on Windows only. If the directories and files used by PBS exist, the `pbs_mkdirs` command fixes their permissions. If the directories and/or files do not exist, the `pbs_mkdirs` command creates them, with the correct permissions. The `pbs_mkdirs` command always examines the following directories and files:

`pbs.conf`
`PBS_EXEC`
`PBS_HOME/spool`
`PBS_HOME/undelivered`
`PBS_HOME/pbs_environment`

2.21.2.1 Required Privilege

You must have Administrator privilege to run this command.

2.21.3 Options

mom
: The `pbs_mkdirs` command examines the following additional items:

`PBS_HOME/mom_priv`
`PBS_HOME/mom_logs`

(no options)
: The `pbs_mkdirs` command examines all of the files and directories specified for the `mom` option.

2.21.4 See Also

The PBS Professional Administrator's Guide, "pbs_probe" on page 80

2.22 pbs_mom

Runs the PBS job monitoring and execution daemon

2.22.1 Synopsis

pbs_mom [-a <alarm timeout>] [-C <checkpoint directory>] [-c <config file>] [-d <MoM home directory>] [-L <logfile>] [-M <MoM port>] [-N] [-n <nice value>] [-p|-r] [-R <inter-MoM communication port>] [-S <server port>] [-s <options>]

pbs_mom --version

2.22.2 Description

The `pbs_mom` command starts the PBS job monitoring and execution daemon, called *MoM*.

The standard MoM starts jobs on the execution host, monitors and reports resource usage, enforces resource usage limits, and notifies the server when the job is finished. The MoM also runs any prologue scripts before the job runs, and runs any epilogue scripts after the job runs.

The MoM performs any communication with job tasks and with other MoMs. The MoM on the first vnode on which a job is running manages communication with the MoMs on the remaining vnodes on which the job runs.

The MoM manages one or more vnodes. PBS may treat a host as a set of virtual nodes, in which case one MoM manages all of the host's vnodes. See "Configuring MoMs and Vnodes" on page 37 in the PBS Professional Administrator's Guide.

2.22.2.1 Logging

The MoM's log file is in `PBS_HOME/mom_logs`. The MoM writes an error message in its log file when it encounters any error. If it cannot write to its log file, it writes to standard error. The MoM writes events to its log file. The MoM writes its PBS version and build information to the logfile whenever it starts up or the logfile is rolled to a new file.

2.22.2.2 Required Permission

The executable for `pbs_mom` is in `PBS_EXEC/sbin`, and can be run only by root on Linux, and Admin on Windows.

2.22.2.2.i HPE Systems Running Supported Versions of HPE MPI

A PBS job can run across multiple machines that run supported versions of HPE MPI.

PBS can run using HPE's MPI (MPT) over InfiniBand. See the PBS Professional Administrator's Guide.

2.22.2.3 Effect on Jobs of Starting MoM

When MoM is started or restarted, her default behavior is to leave any running processes running, but to tell the PBS server to requeue the jobs she manages. MoM tracks the process ID of jobs across restarts.

In order to have all jobs killed and requeued, use the `-r` option when starting or restarting MoM.

In order to leave any running processes running, and not to requeue any jobs, use the `-p` option when starting or restarting MoM.

2.22.3 Options to pbs_mom

-a <alarm timeout>

Number of seconds before alarm timeout. Whenever a resource request is processed, an alarm is set for the given amount of time. If the request has not completed before *alarm timeout*, the OS generates an alarm signal and sends it to MoM.

Format: *Integer*

Default: *10 seconds*

-C <checkpoint directory>

Specifies the path to the directory where MoM creates job-specific subdirectories used to hold each job's restart files. MoM passes this path to checkpoint and restart scripts. Overrides other checkpoint path specification methods. Any directory specified with the -c option must be owned, readable, writable, and executable by root only (*rwx,---,---*, or *0700*), to protect the security of the restart files. See the -d option to pbs_mom and "Specifying Checkpoint Path" on page 397 in the PBS Professional Administrator's Guide.

Format: *String*

Default: PBS_HOME/checkpoint

-c <config file>

MoM will read this alternate default configuration file upon starting. If this is a relative file name it is relative to PBS_HOME/mom_priv. If the specified file cannot be opened, pbs_mom will abort. See the -d option.

MoM's normal operation, when the -c option is not given, is to attempt to open the default configuration file PBS_HOME/mom_priv/config. If this file is not present, pbs_mom will log the fact and continue.

-d <MoM home directory>

Specifies the path of the directory to be used in place of PBS_HOME by pbs_mom. The default directory is given by $PBS_HOME.

Format: *String*

-L <logfile>

Specifies an absolute path and filename for the log file. The default is a file named for the current date in PBS_HOME/mom_logs/. See the -d option.

Format: *String*.

-M <MoM port>

Specifies the port number on which MoM will listen for server requests and instructions. Overrides PBS_MOM_SERVICE_PORT setting in pbs.conf and environment variable.

Format: *Integer port number*.

Default: *15002*.

-n <nice value>

Specifies the priority for the pbs_mom daemon.

Format: *Integer*.

-N

Specifies that when starting, MoM should not detach from the current session.

-p

Specifies that when starting, MoM should allow any running jobs to continue running, and not have them requeued. Cannot be used with the -r option. MoM is not the parent of these jobs.

-r

Specifies that when starting, MoM should requeue any rerunnable jobs and kill any non-rerunnable jobs that she was tracking, and mark the jobs as terminated. Cannot be used with the -p option. MoM is not the parent of these jobs.

It is not recommended to use the -r option after a reboot, because process IDs of new, legitimate tasks may match those MoM was previously tracking. If they match and MoM is started with the -r option, MoM will kill the new tasks.

-R <inter-MoM communication port>

Specifies the port number on which MoM will listen for pings, resource information requests, communication from other MoMs, etc. Overrides PBS_MANAGER_SERVICE_PORT setting in pbs.conf and environment variable.

Format: *Integer port number*

Default: *15003*

-S <server port>

Specifies the port number on which pbs_mom initially contacts the server.

Format: *Integer port number*

Default: *15001*

-s <file options>

If you are running the cgroups hook, make sure that the vnode names in any Version 2 configuration file exactly match those in the output of pbsnodes -av.

This option lets you add, delete, and display Version 2 configuration files. Run this command at the host you want to change. The *file options* are used this way:

-s insert <Version 2 filename> <inputfile>

Reads *inputfile* and copies it to a Version 2 vnode configuration file with the filename *Version 2 filename*. For example, to create a Version 2 file named "Myhost_V2":

```
pbs_mom -s insert <Myhost_V2> <myhost_v2_input>
```

If a configuration file with the specified *Version 2 filename* already exists, the operation fails, and pbs_mom prints a diagnostic and exits with a nonzero status. Configuration files whose names begin with the prefix "*PBS*" are reserved. You cannot add a file whose name begins with "*PBS*"; pbs_mom will print a diagnostic message and exit with a nonzero status.

-s remove <Version 2 filename>

Removes the configuration file named *Version 2 filename* if it exists. Example:

```
pbs_mom -s remove <Version 2 filename>
```

If the file does not exist or if you try to remove a file with the reserved "PBS" prefix, the operation fails, and pbs_mom prints a diagnostic and exits with a nonzero status.

-s show <Version 2 filename>

Prints the contents of the named file to standard output. Example:

```
pbs_mom -s show <Version 2 filename>
```

If *Version 2 filename* does not exist, the operation fails and pbs_mom writes a diagnostic and exits with a nonzero status.

-s list

MoM lists the PBS-prefixed and site-defined configuration files in the order in which they are executed. Example:

```
pbs_mom -s list
```

WINDOWS:

Under Windows, use the -N option so that pbs_mom will start up as a standalone program. For example:

```
pbs_mom -N -s insert <Version 2 filename> <inputfile>
```

or

```
pbs_mom -N -s list
```

--version

The pbs_mom command returns its PBS version information and exits. This option can only be used alone.

2.22.4 Files and Directories

$PBS_HOME/mom_priv

Default directory for default configuration files.

$PBS_HOME/mom_priv/config

MoM's default configuration file.

$PBS_HOME/mom_logs

Default directory for log files written by MoM.

$PBS_HOME/mom_priv/prologue

File containing administrative script to be run before job execution.

$PBS_HOME/mom_priv/epilogue

File containing administrative script to be run after job execution.

2.22.5 Signal Handling

pbs_mom handles the following signals:

SIGHUP

The pbs_mom daemon rereads its configuration files, closes and reopens the log file, and reinitializes resource structures.

SIGALRM

MoM writes a log file entry. See the -a <alarm timeout> option.

SIGINT

The pbs_mom daemon exits, leaving all running jobs still running. See the -p option.

SIGKILL

This signal is not caught. The pbs_mom daemon exits immediately.

SIGTERM, SIGXCPU, SIGXFSZ, SIGCPULIM, SIGSHUTDN

The pbs_mom daemon terminates all running children and exits.

SIGPIPE, SIGUSR1, SIGUSR2, SIGINFO

These are ignored.

All other signals have their default behavior installed.

2.22.6 Exit Status

Zero

Upon success

Greater than zero

- If the `pbs_mom` daemon fails to start
- If the `-s insert` option is used with an existing *Version 2 filename*
- If the administrator attempts to add a script whose name begins with "*PBS*"
- If the administrator attempts to use the `-s remove` option on a nonexistent configuration file, or on a configuration file whose name begins with "*PBS*"
- If the administrator attempts to use the `-s show` option on a nonexistent script

2.22.7 See Also

The PBS Professional Administrator's Guide

2.23 pbs_mpihp

Runs an MPI application in a PBS job with HP MPI

2.23.1 Synopsis

pbs_mpihp [-h <hostname>] [-np <number>] [<other HP mpirun options>] <program> [<args>]

pbs_mpihp [<HP mpirun options>] -f <appfile> [-- [<extra args>]]

pbs_mpihp --version

2.23.2 Description

The PBS command `pbs_mpihp` replaces the standard `mpirun` command in a PBS HP MPI job, for executing programs. `pbs_mpihp` is a front end to the HP MPI version of `mpirun`.

When `pbs_mpihp` is invoked from a PBS job, it processes the command line arguments, then calls standard HP `mpirun` to actually start the MPI ranks. The ranks created are mapped onto CPUs on the vnodes allocated to the PBS job. The environment variable MPI_REMSH is set to `$PBS_EXEC/bin/pbs_tmrsh`. This causes the processes that are created to become part of the PBS job.

The path to standard HP `mpirun` is found by checking to see if a link exists with the name `PBS_EXEC/etc/pbs_mpihp`. If this link exists, it points to standard HP `mpirun`. If it does not exist, a call to `mpirun -version` is made to determine whether it is HP `mpirun`. If so, the call is made to "`mpirun`" without an absolute path. If HP `mpirun` cannot be found, an error is output, all temp files are cleaned up and the script exits with value 127.

If `pbs_mpihp` is invoked from outside a PBS job, it passes all of its arguments directly to standard HP `mpirun` without further processing.

2.23.2.1 Configuration

When HP MPI is wrapped with `pbs_mpihp`, "`rsh`" is the default used to start the mpids. If you wish to use "`ssh`" or something else, be sure to set the following in `$PBS_HOME/pbs_environment`:

```
PBS_RSHCOMMAND=ssh
```

or put the following in the job script:

```
export PBS_RSHCOMMAND=<rsh_cmd>
```

2.23.2.2 Usage

Usage is the same as for HP `mpirun`.

`pbs_mpihp <program>` allows one executable to be specified.

`pbs_mpihp -f <appfile>` uses an *appfile* to list multiple executables. The format is described in the HP `mpirun` man page. If this form is used from inside a PBS job, the file is read to determine what executables are to be run and how many processes are started for each.

Executing `pbs_mpihp` with the `-client` option is not supported under PBS.

2.23.3 Options to `pbs_mpihp`

All options except the following are passed directly to HP `mpirun` with no modification.

-client
Not supported.

-f <appfile>
The specified *appfile* is read by `pbs_mpihp`.

-h <hostname>
Ignored by `pbs_mpihp`.

-l <username>
Ignored by `pbs_mpihp`.

-np <number>
Specifies the *number* of processes to run on the PBS vnodes.

--version
The `pbs_mpihp` command returns its PBS version information and exits. This option can only be used alone.

2.23.4 Exit Values

127
If HP `mpirun` cannot be found

2.23.5 See Also

The PBS Professional Administrator's Guide
`mpirun(1)`

2.24 pbs_mpirun

Deprecated. Runs MPI programs under PBS with MPICH

2.24.1 Synopsis

pbs_mpirun [<mpirun options>]

pbs_mpirun --version

2.24.2 Description

The PBS command `pbs_mpirun` replaces the standard `mpirun` command in a PBS MPICH job using P4.

On Windows, this command cannot be used to start job processes or track a job's resource usage.

2.24.2.1 Prerequisite

The PATH on remote machines must contain `PBS_EXEC/bin`.

2.24.2.2 Usage

Usage is the same as for `mpirun`, except for the `-machinefile` option. All other options are passed directly to `mpirun`.

2.24.3 Options to `pbs_mpirun`

<mpirun options>

The options to `pbs_mpirun` are the same as for `mpirun`, except for the `-machinefile` option. This is generated by `pbs_mpirun`. The user should not attempt to specify `-machinefile`.

The value for `-machinefile` is a temporary file created from PBS_NODEFILE in the format:

```
hostname-1[:number of processors]
hostname-2[:number of processors]
hostname-n[:number of processors]
```

where if the number of processors is not specified, it is *1*. An attempt by the user to specify the `-machinefile` option will result in a warning saying "`Warning, -machinefile value replaced by PBS`".

The default value for the `-np` option is the number of entries in PBS_NODEFILE.

--version

The `pbs_mpirun` command returns its PBS version information and exits. This option can only be used alone.

2.24.4 Environment Variables

`pbs_mpirun` modifies P4_RSHCOMMAND and PBS_RSHCOMMAND. Users should not edit these. `pbs_mpirun` copies the value of P4_RSHCOMMAND into PBS_RSHCOMMAND.

2.24.5 See Also

The PBS Professional Administrator's Guide, `mpirun(1)`

2.25 pbs_probe

Deprecated. Reports PBS diagnostic information and fixes permission errors

2.25.1 Synopsis

pbs_probe [-f | -v]

pbs_probe --version

2.25.2 Description

The `pbs_probe` command reports post-installation information useful for PBS diagnostics, and fixes permission errors.

2.25.2.1 Information Sources

- Information that is supplied on the command line
- The file `/etc/pbs.conf`
- The file `/etc/init.d/pbs`
- The values of any of the following environment variables; these may be set in the environment in which `pbs_probe` is run: PBS_CONF_FILE, PBS_HOME, PBS_EXEC, PBS_START_SERVER, PBS_START_MOM, and PBS_START_SCHED

2.25.2.2 Required Privilege

In order to execute `pbs_probe`, you must have PBS Operator or Manager privilege.

2.25.3 Options to `pbs_probe`

(no options)

Run in "report" mode. In this mode `pbs_probe` reports any permission errors detected in PBS infrastructure files. The command categorizes the errors and writes a list of them by category. Empty categories are not written.

-f

Run in "fix" mode. In this mode `pbs_probe` examines each of the relevant infrastructure files and, where possible, fixes any permission errors that it detects, and prints a message saying what got changed. If it is unable to fix a problem, it prints a message saying what was detected.

-v

Run in "verbose" mode. In this mode `pbs_probe` writes a complete list of the infrastructure files that it checked.

--version

The `pbs_probe` command returns its PBS version information and exits. This option can only be used alone.

2.25.4 Standard Error

The `pbs_probe` command writes a diagnostic message to standard error for each error occurrence.

2.25.5 Exit Status

Exit code does not reflect results of probe; it reflects whether or not the program ran.

Zero
: When run correctly, whether or not `pbs_probe` finds any problems or errors

Non-negative
: When run incorrectly

2.25.6 See Also

The PBS Professional Administrator's Guide

2.26 pbs_python

Python interpreter for debugging a hook script from the command line

2.26.1 Synopsis

pbs_python --hook [-e <log event mask>] [-i <event input file>] [-L <log dir>] [-l <log file>] [-o <hook execution record>] [-r <resourcedef file>] [-s <site data file>] [<Python script>]

pbs_python <standard Python options>

pbs_python --version

2.26.2 Description

The PBS Python interpreter, `pbs_python`, is a wrapper for Python.

You can use the `pbs_python` wrapper that is shipped with PBS to debug hooks. Either:

- Use the `--hook` option to `pbs_python` to run `pbs_python` as a wrapper to Python, employing the `pbs_python` options. With the `--hook` option, you cannot use the standard Python options. The rest of this section covers how to use `pbs_python` with the `--hook` option.
- Do not use the `--hook` option, so `pbs_python` runs the Python interpreter, with the standard Python options, and without access to the `pbs_python` options.

2.26.2.1 Debugging Hooks

You can get each hook to write out debugging files, and then modify the files and use them as debugging input to `pbs_python`. Alternatively, you can write the files yourself.

Debugging files can contain information about the event, about the site, and about what the hook changed. You can use these as inputs to a hook when debugging.

For a complete description of using `pbs_python` with debugging files, see "Debugging Hooks" on page 183 in the PBS Professional Hooks Guide.

2.26.3 Options to `pbs_python`

--hook

This option is a switch. When you use this option, you can use the PBS Python module (via "`import pbs`"), and the other options described here are available. When you use this option, you cannot use the standard Python options. This option is useful for debugging.

When you do not use this option, you cannot use the other options listed here, but you can use the standard Python options.

-e <log event mask>

Sets the mask that determines which event types are logged by `pbs_python`. To see only debug messages, set the value to *0xd80*. To see all messages, set the value to *0xffff*. The `pbs_python` interpreter uses the same set of mask values that are used for the $logevent <mask> entry in the `pbs_mom` configuration file. See section 2.22, "pbs_mom", on page 71. Available only when `--hook` option is used.

-i <event input file>

Text file containing data to populate pbs.event() objects. Each line specifies an attribute value or a resource value. Syntax of each input line is one of the following:

<object name>.<attribute name>=<attribute value>

<object name>.<resource list>[<resource name>]=<resource value>

Where

<object name> is a PBS object name which can refer to its sub-objects. Examples: *"pbs.event()", "pbs.event().job", "pbs.event().vnode_list["<vnode name>"]"*.

Example input file:

```
pbs.event().hook_name=proto
pbs.event().hook_type=site
pbs.event().type=queuejob
pbs.event().requestor=user1
pbs.event().requestor_host=host1
pbs.event().alarm=40
pbs.event().job.id=72
pbs.event().job.Job_Name=job1
pbs.event().job.Resource_List[ncpus]=5
pbs.event().job.Resource_List[mem]=6mb
pbs.event().vnode_list["host1"].resources_available["ncpus"] = 5
pbs.event().vnode_list["host1"].resources_available["mem"] = 300gb
```

Available only when `--hook` option is used.

-L <log dir>

Directory holding the log file where pbs.logmsg() and pbs.logjobmsg() write their output. Default is current working directory where `pbs_python` is executed. Available only when `--hook` option is used.

-l <log file>

Log file where pbs.logmsg() and pbs.logjobmsg() write their output. Default file name is current date in *yyyymmdd* format. Available only when `--hook` option is used.

-o <hook execution record>

The hook execution record contains the changes made after executing the hook script, such as the attributes and resources set in any pbs.event() jobs and reservations, whether an action was accepted or rejected, and any pbs.reject() messages.

Example hook execution record:

```
pbs.event().job.Job_Name=job2
pbs.event().job.Resource_List[file]=60gb
pbs.event().job.Resource_List[ncpus]=5
pbs.event().job.Resource_List[mem]=20gb
pbs.event().job.Account_Name=account2
pbs.event().reject=True
pbs.event().reject_msg=No way!
```

Without this option, output goes to `stdout`. Available only when `--hook` option is used.

-r <resourcedef file>

File/path name containing a resource definition specifying a custom resource whose Python type is pbs.resource. Format:

<resource name> type=<typename> [flag=<value>]

Available only when `--hook` option is used.

-s <site data file>

The site data file can contain any relevant information about the server, queues, vnodes, and jobs at the server. This file can be written by a hook or by the administrator.

When the hook writes it, this file contains the values that populate the server, queues, vnodes, reservations, and jobs, with all attributes and resources for which there are values.

The site data file is named *hook_<event type>_<hook name>_<random integer>.data*. It can be passed to `pbs_python` using the `-s <site data file>` option.

Available only when `--hook` option is used.

--version

The `pbs_python` command prints its version information and exits. This option can only be used alone.

2.26.4 Arguments

<Python script>

The hook script to execute. We recommend importing the PBS Python module at the start of the script:

```
import pbs
```

If you do not specify <*Python script*>, you can perform interactive debugging. If you type the following:

```
% pbs_python --hook -i hook.input
```

The interpreter displays a prompt:

```
>>
```

You can type your Python lines at the prompt:

```
>>import pbs
>> e=pbs.event().job
>> print e.id
<job ID>
...
```

2.27 pbs_ralter

Modifies an existing reservation

2.27.1 Summary

Alter an existing advance, standing, or job-specific reservation.

2.27.2 Synopsis

pbs_ralter [-D <duration>] [-E <end time>] [-G <auth group list>] [-I <block time>] [-l select=<select spec>] [-m <mail points>] [-M <mail list>] [-N <reservation name>] [-R <start time>] [-U <auth user list>] <reservation ID>

pbs_ralter -Wforce [-D <duration>] [-E <end time>] [-R <start time>] <reservation ID>

pbs_ralter -Wdelete_idle_time=<value>

pbs_ralter --version

2.27.3 Description

You can use the `pbs_ralter` command to alter an existing reservation, whether it is an individual job-specific, advance, or maintenance reservation, or the next or current occurrence of a standing reservation. You can change the start time, end time, duration, events that generate mail, mail recipient list, authorized groups, authorized users, select specification, and reservation name.

The PBS Administrator can use the `-Wforce` option to this command to change the start time, end time, or duration of a reservation; this option overrides the scheduler's actions.

After the change is requested, the change is either confirmed or denied. On denial of the change, the reservation is not deleted and is left as is, and the following message appears in the server's log:

```
Unable to alter reservation <reservation ID>
```

When a reservation is confirmed, the following message appears in the server's log:

```
Reservation alter successful for <reservation ID>
```

To find out whether or not the change was allowed:

- Use the `pbs_rstat` command to see whether you altered reservation attribute(s)
- Use the interactive option to check for confirmation after the blocking time has run out
- Check the server log for confirmation or denial messages

Before the change is confirmed or denied, the change is unconfirmed, and the reservation state is *AL*.

Once a reservation change is confirmed, the reservation state is *CO* or *RN*.

If the reservation has not started and it cannot be confirmed on the same vnodes, PBS searches for another set of vnodes.

If the reservation is altered, PBS logs a Y accounting record. See "Types of Accounting Log Records" on page 532 in the PBS Professional Administrator's Guide.

2.27.3.1 Caveats and Restrictions

You cannot change the start time of a reservation if jobs are running in it.

If you change the end time of a reservation so that it ends before a job running in the reservation finishes, the job is killed when the reservation ends.

If you change the select specification, the vnodes where jobs are running remain the same, but all other vnodes may change.

Do not attempt to alter a maintenance reservation.

Altering a reservation may change how top jobs are able to run, because altering a reservation has the same privilege as submitting a reservation.

2.27.3.2 Required Privilege

Without the `-Wforce` option, this command can be used by the reservation owner or the PBS Administrator.

With the `-Wforce` option, this command can be used only by the PBS Administrator.

2.27.4 Options to pbs_ralter

-D <duration>

Specifies reservation's new duration. This option can be used even when the reservation is running and has jobs that are submitted to and/or are running in the reservation.

Can be specified with start and/or end time. PBS calculates anything not specified. When specified without start or end time, PBS keeps previous start time.

If you change the duration to less than the time the reservation has already run, PBS deletes the reservation.

Format: *Duration*, as *seconds* or *hh:mm:ss*

-E <end time>

Specifies reservation's new end time. This option can be used even when the reservation is running and has jobs that are submitted to and/or are running in the reservation.

Format: *Datetime*

-G <auth group list>

Comma-separated list of names of groups who can or cannot submit jobs to this reservation. Sets reservation's Authorized_Groups attribute to *auth group list*.

This list becomes the acl_groups list for the reservation's queue.

More specific entries should be listed before more general, because the list is read left-to-right, and the first match determines access.

If both the Authorized_Users and Authorized_Groups reservation attributes are set, a user must belong to both in order to be able to submit jobs to this reservation.

Group names are interpreted in the context of the server host, not the context of the host from which the job is submitted.

See the Authorized_Groups reservation attribute in section 6.8, “Reservation Attributes”, on page 303.

Syntax:

[+|-]<group name>[,[+|-]<group name> ...]

Default: no default; group names are unchanged

-I <block time>

(Capital I) Specifies interactive mode. The `pbs_ralter` command will block, up to *block time* seconds, while waiting for the reservation's change request to be confirmed or denied.

The value for *block time* must be positive. The `pbs_ralter` command returns either the status "*CONFIRMED*" or the status "*DENIED*".

Format: *Integer*

Default: *Not interactive*

-l select=<select spec>

(Lowercase L) Specifies new select specification for reservation. New specification can shrink the reservation using a subset of the same chunks requested by the original reservation, or can grow the reservation by specifying more chunks.

If jobs are running in the reservation:

- You cannot release chunks where reservation jobs are running
- Vnodes where jobs are running cannot change, but everything else can.

If no jobs are running, the select specification can be changed completely.

When requesting chunks, make sure each chunk request specifies chunks of a single type.

-m <mail points>

Specifies the set of events that cause mail to be sent to the list of users specified in the `-M <mail list>` option.

Format: String

Syntax: Either of:

- Any combination of "*a*", "*b*", "*c*" or "*e*"
- The single character "*n*"

Table 2-4: Suboptions to -m Option

Character	Meaning
a	Notify if reservation is terminated for any reason
b	Notify when the reservation period begins
c	Notify when the reservation is confirmed
e	Notify when the reservation period ends
n	Send no mail. Cannot be used with any of a, b, c or e.

Default: No default; if not specified, mail events are unchanged.

-M <mail list>

The list of users to whom mail is sent whenever the reservation transitions to one of the states specified in the -m <mail points> option.

Format: *<username>[@<hostname>][,<username>[@<hostname>]...]*

Default: No default; if not specified, user list is unchanged.

-N <reservation name>

Specifies a name for the reservation.

Format: String up to 15 characters in length. It must consist of printable, non-white space characters with the first character alphabetic.

Default: No default; if not specified, reservation name is unchanged.

-R <start time>

Specifies reservation's new start time. This option can be used either when the reservation is not running or there are no jobs are submitted to the reservation. You cannot use this option when a reservation is not empty and has started running.

The specifications for providing the time are the same as for `pbs_rsub`:

If the day, DD, is not specified, it defaults to today if the time hhmm is in the future. Otherwise, the day is set to tomorrow. For example, if you alter a reservation with the specification `-R 1110` at 11:15 a.m., it is interpreted as being for 11:10 a.m. tomorrow. If the month portion, MM, is not specified, it defaults to the current month, provided that the specified day DD, is in the future. Otherwise, the month is set to next month. Similar rules apply to the two other optional, left-side components.

Format: *Datetime*

-U <auth user list>

Comma-separated list of users who are and are not allowed to submit jobs to this reservation. Sets reservation's Authorized_Users attribute to *auth user list*.

This list becomes the acl_users attribute for the reservation's queue.

More specific entries should be listed before more general, because the list is read left-to-right, and the first match determines access. The reservation creator's username is automatically added to this list, whether or not the reservation creator specifies this list.

If both the Authorized_Users and Authorized_Groups reservation attributes are set, a user must belong to both in order to be able to submit jobs to this reservation.

See the Authorized_Users reservation attribute in section 6.8, “Reservation Attributes”, on page 303.

Syntax:

[+|-]<username>[@<hostname>][,[+|-]<username>[@<hostname>]...]

Default: no default; user list is unchanged

-W<extended options>

This allows you to define other attributes for the reservation or perform other actions.

delete_idle_time=<allowed idle time>

Sets the reservation's delete_idle_time attribute to *allowed idle time*. Deletes the reservation after the specified amount of idle time. Applies to each instance of a standing reservation.

If the reservation is running and empty, the existing idle timer is restarted with the new value. If the reservation is not empty, the idle timer uses the new value the next time it starts.

The default value for the delete_idle_time attribute for an ASAP reservation is 10 minutes.

This option cannot be used when changing any other reservation attributes.

Format for *allowed idle time* is a duration.

To unset the delete_idle_time attribute, set it to an empty string:

```
pbs_ralter -Wdelete_idle_time=""
```

force

Enforces changes made to the reservation start time, end time, or duration, regardless of the actions of the scheduler. Can be used only by the PBS Administrator. Note that with this option you can force PBS to oversubscribe resources, in which case you (the administrator) may need to manage them yourself. Cannot be used to change the start time of a reservation in which jobs are running.

--version

The `pbs_ralter` command returns its PBS version information and exits. This option can only be used alone.

2.27.5 Operands

The `pbs_ralter` command takes a reservation ID.

For an advance or job-specific reservation this has the form:

R<sequence number>[.<server name>][@<remote server>]

For a standing reservation this has the form:

S<sequence number>[.<server name>][@<remote server>]

For a maintenance reservation this has the form:

M<sequence number>[.<server name>][@<remote server>]

@<remote server> specifies a reservation at a server other than the default server.

2.28 pbs_rdel

Deletes a PBS reservation

2.28.1 Synopsis

pbs_rdel <reservation ID>[,<reservation ID>...]

pbs_rdel --version

2.28.2 Description

The `pbs_rdel` command deletes reservations in the order specified.

This command deletes the specified reservations, whether or not they are running, all jobs in the reservations, and the reservation queues.

You can delete an entire standing reservation, but not just one instance of a standing reservation.

2.28.3 Required Privilege

A reservation may be deleted by its owner, a PBS Operator, or a PBS Manager.

2.28.4 Options

--version
: The `pbs_rdel` command returns its PBS version information and exits. This option can only be used alone.

2.28.5 Operands

The `pbs_rdel` command accepts one or more *reservation ID* operands.

For an advance or job-specific reservation this has the form:

R<sequence number>[.<server name>][@<remote server>]

For a standing reservation this has the form:

S<sequence number>[.<server name>][@<remote server>]

For a maintenance reservation this has the form:

M<sequence number>[.<server name>][@<remote server>]

@<remote server> specifies a reservation at a server other than the default server.

2.28.6 Exit Status

Zero
: Upon success

Greater than zero
: Upon failure to process any operand

2.28.7 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide, "pbs_rsub" on page 96, "pbs_rstat" on page 94, "Reservation Attributes" on page 303

2.29 pbs_release_nodes

Releases vnodes assigned to a PBS job

2.29.1 Synopsis

pbs_release_nodes [-j <job ID>] [-k (<number of hosts to keep> | <selection of vnodes to keep>)] <vnode> [<vnode> [<vnode>] ...]

pbs_release_nodes [-j <job ID>] -a

pbs_release_nodes --version

2.29.2 Description

You can use the `pbs_release_nodes` command to release no-longer-needed sister hosts or vnodes assigned to a running job, before the job would normally release them. These vnodes are then available for use by other jobs.

You can specify the names of sister vnodes to be released, or you can release all sister vnodes not on the primary execution host that are assigned to a running job via the `-a` option.

PBS can keep the number of sister hosts you specify, or PBS can release all sister vnodes except for the ones you specify via a select statement.

Can be used on jobs and subjobs, but not on job arrays or ranges of subjobs.

2.29.2.1 Caveats and Restrictions

- You can release only sister hosts or vnodes that are not on the primary execution host. You cannot release vnodes on the primary execution host.
- The job must be running (in the *R* state).
- If cgroups support is enabled, and `pbs_release_nodes` is called to release some but not all the vnodes managed by a MoM, resources on those vnodes are released.
- You cannot release a partial host. If you try to release some but not all of a host, the job's exec_vnode attribute shows the new, smaller list of vnodes, but the `pbsnodes` command will reveal that the host is still allocated to the job.
- If you specify release of a vnode on which a job process is running, that process is terminated when the vnode is released.

2.29.2.2 Required Privilege

This command can be run by the job owner, the PBS Manager, Operator, and Administrator, as well as root on Linux and Admin on Windows.

2.29.3 Options to pbs_release_nodes

-a

Releases all job vnodes not on the primary execution host. Cannot be used with `-k` option, or with list of vnode names.

-j <job ID>

Specifies the job ID for the job or subjob whose vnode(s) are to be released.

-k <keep number> | <keep selection>

Use *keep number* to specify how many sister hosts to keep.

Use *keep selection* to specify which sister vnodes to keep. The *keep selection* is a select statement beginning with "select=" specifying which vnodes to keep.

The primary execution host and its vnodes are not released.

For example, to release all sister hosts except 8:

```
pbs_release_nodes -k 8
```

To release all sister vnodes except for 4 of the ones marked with "bigmem":

```
pbs_release_nodes -k select=4:bigmem=true
```

Cannot be used with `-a` option or with vnode list argument.

(no options)

With no options, `pbs_release_nodes` uses the value of the PBS_JOBID environment variable as the job ID of the job whose vnodes are to be released.

--version

The `pbs_release_nodes` command returns its PBS version information and exits. This option can only be used alone.

2.29.4 Operands for pbs_release_nodes

The `pbs_release_nodes` command can take as an operand a list of vnodes. Format:

<vnode name> [<vnode name> [<vnode name>] ...]

Cannot be used with the `-a` option.

2.29.5 Usage

This command can be run at the command line, or called inside a job script, where it can use the value of the PBS_JOBID environment variable.

You can release any vnode that appears in the job's exec_vnode attribute that is not on the primary execution host. You can release a particular set of a job's vnodes, or you can release all of a job's non-primary-execution-host vnodes.

To release specific vnodes:

pbs_release_nodes [-j <job ID>] <vnode name> [<vnode name>] ...]

To release all of a job's vnodes that are not on the primary execution host:

pbs_release_nodes [-j <job ID>] -a

To release all except a specified number of vnodes:

pbs_release_nodes -k <number of sister hosts to keep>

To release all vnodes except for those in a select specification:

pbs_release_nodes -k <select specification>

2.30 pbs_rstat

Shows status of PBS reservations

2.30.1 Synopsis

pbs_rstat [-B] [-f|-F] [-S] [<reservation ID>...]

pbs_rstat --version

2.30.2 Description

The `pbs_rstat` command shows the status of all reservations at the PBS server. Denied reservations are not displayed.

2.30.2.1 Required Privilege

This command can be run by a user with any level of PBS privilege. For full output, users without manager or operator privilege cannot print custom resources which were created to be invisible to users.

2.30.3 Output

The `pbs_rstat` command displays output in any of brief, short, or full formats.

See section 6.8, “Reservation Attributes”, on page 303 and section 8.6, “Reservation States”, on page 367.

2.30.4 Options to `pbs_rstat`

-B
: Brief output. Displays each reservation identifier only.

-f, -F
: Full output. Displays all reservation attributes that are not set to the default value. Users without manager or operator privilege cannot print custom resources which were created to be invisible to users.

-S
: Short output. Displays a table showing the name, queue, owner, state, start time, duration, and end time of each reservation.

--version
: The `pbs_rstat` command returns its PBS version information and exits. This option can only be used alone.

(no options)
: Short output. Same behavior as `-S` option.

2.30.5 Operands

The `pbs_rstat` command accepts one or more *reservation ID* operands.

Format for an advance or job-specific reservation:

R<sequence number>[.<server name>][@<remote server>]

Format for a standing reservation:

S<sequence number>[.<server name>][@<remote server>]

Format for a maintenance reservation:

M<sequence number>[.<server name>][@<remote server>]

@<remote server> specifies a reservation at a server other than the default server.

2.30.6 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide, "Reservation Attributes" on page 303

2.31 pbs_rsub

Creates a PBS reservation

2.31.1 Synopsis

For advance and standing reservations:

pbs_rsub [-D <duration>] [-E <end time>] [-g <group list>] [-G <auth group list>] [-H <auth host list>] [-I <block time>] [-l <placement>] [-l <resource request>] [-m <mail events>] [-M <mail list>] [-N <reservation name>] [-q <destination>] [-r <recurrence rule>] [-R <start time>] [-u <user list>] [-U <auth user list>] [-W <attribute value list>]

For job-specific now reservations:

pbs_rsub [-I <block time>] [-m <mail events>] [-M <mail list>] --job <job ID>

For maintenance reservations:

pbs_rsub [-D <duration>] [-E <end time>] [-g <group list>] [-G <auth group list>] [-H <auth host list>] [-m <mail events>] [-M <mail list>] [-N <reservation name>] [-q <destination>] [-R <start time>] [-u <user list>] [-U <auth user list>] --hosts <host list>

For version information:

pbs_rsub --version

2.31.2 Description

The `pbs_rsub` command is used to create advance, standing, job-specific now, job-specific ASAP, or maintenance reservations. For creating job-specific start reservations, see "qsub" on page 216.

- An advance reservation reserves specific resources for the requested time period.
- A standing reservation reserves specific resources for recurring time periods.
- A job-specific now reservation reserves the resources being used by a specific job in case the job fails and needs to be re-submitted, allowing it to run again without having to wait to be scheduled. The reservation is created and starts running when a queued job starts running, or immediately when you use `pbs_rsub --job <job ID>` on a running job.
- A job-specific ASAP reservation is created from a queued job via `pbs_rsub -Wqmove=<job ID>`. The reservation runs as soon as possible, and the job is moved into the reservation. The reservation is created using the same resources as the job requested.
- A job-specific start reservation is created immediately using a running job's resources, and the job is moved into the reservation. You create job-specific start reservations using `qsub -Wcreate_resv_from_job=true` on a running job or when you `qalter` a job to set the job's create_resv_from_job attribute to *True*. See the `qsub` command.
- A maintenance reservation reserves the specified hosts for the specified time regardless of other circumstances.

Advance, standing, and job-specific reservations are "job reservations", to distinguish them from maintenance reservations. When a reservation is created, it has an associated queue.

To get information about a reservation, use the `pbs_rstat` command.

To delete a reservation, use the `pbs_rdel` command. Do not use the `qdel` command.

The behavior of the pbs_rsub command may be affected by any site hooks. Site hooks can modify the reservation's attributes.

2.31.2.1 Job Reservations

After an advance or standing reservation is requested, it is either confirmed or denied. A job-specific now reservation is created when the job is started and confirmed immediately. A job-specific ASAP reservation is scheduled as soon as possible. Once the reservation has been confirmed, authorized users submit jobs to the reservation's queue via qsub and qmove.

A confirmed job reservation will accept jobs at any time. The jobs in its queue can run only during the reservation period. Jobs in a single advance reservation or job-specific reservation can run only during the reservation's time slot, and jobs in a standing reservation can run only during the time slots of occurrences of the standing reservation.

When an advance reservation ends, all of its jobs are deleted, whether running or queued. When an occurrence of a standing reservation ends, only its running jobs are deleted; those jobs still in the queue are not deleted.

2.31.2.2 Maintenance Reservations

You can create maintenance reservations using pbs_rsub --hosts <host list>. Maintenance reservations are designed to make the specified hosts available for the specified amount of time, regardless of what else is happening:

- You can create a maintenance reservation that includes or is made up of vnodes that are down or offline.
- Maintenance reservations ignore the value of a vnode's resv_enable attribute.
- PBS immediately confirms any maintenance reservation.
- Maintenance reservations take precedence over other reservations; if you create a maintenance reservation that overlaps an advance or standing job reservation, the overlapping vnodes become unavailable to the job reservation, and the job reservation is in conflict with the maintenance reservation. PBS looks for replacement vnodes; see "Reservation Fault Tolerance" on page 401 in the PBS Professional Administrator's Guide.

PBS will not start any new jobs on vnodes overlapping or in a maintenance reservation. However, jobs that were already running on overlapping vnodes continue to run; you can let them run or requeue them.

You cannot specify place or select for a maintenance reservation; these are created by PBS:

- PBS creates the reservation's placement specification so that hosts are assigned exclusively to the reservation. The placement specification is always the following:

  -lplace=exclhost
- PBS sets the reservation's resv_nodes attribute value so that all CPUs on the reserved hosts are assigned to the maintenance reservation. The select specification is always the following:

  -lselect=host=<host1>:ncpus=<number of CPUs at host1>+host=<host2>:ncpus=<number of CPUs at host2>+...

Maintenance reservations are prefixed with *M*. A maintenance reservation ID has the format:

M<sequence number>.<server name>

You cannot create a recurring maintenance reservation.

Creating a maintenance reservation does not trigger a scheduling cycle.

You must have manager or operator privilege to create a maintenance reservation.

2.31.2.3 Requirements

When using pbs_rsub to request a standing, advance, or maintenance reservation, you must specify two of the following options: -R, -E, and -D. The resource request -l walltime can be used instead of the -D option.

If you want to run jobs in a reservation that will request exclusive placement, you must create the reservation with exclusive placement via `-l place=excl`.

2.31.3 Options to `pbs_rsub`

-D <duration>

Specifies reservation duration. If the start time and end time are the only times specified, this duration time is calculated.

Format: *Duration*

Default: none

-E <end time>

Specifies the reservation end time. If start time and duration are the only times specified, the end time value is calculated.

Format: *Datetime.*

Default: none

-g <group_list>

The *group list* is a comma-separated list of group names. The server uses entries in this list, along with an ordered set of rules, to associate a group name with the reservation. The reservation creator's primary group is automatically added to this list.

Format: *<group>@<hostname>[,<group>@<hostname> ...]*

-G <auth group list>

Comma-separated list of names of groups who can or cannot submit jobs to this reservation. Sets reservation's Authorized_Groups attribute to *auth group list*.

This list becomes the acl_groups list for the reservation's queue.

More specific entries should be listed before more general, because the list is read left-to-right, and the first match determines access.

If both the Authorized_Users and Authorized_Groups reservation attributes are set, a user must belong to both in order to be able to submit jobs to this reservation.

Group names are interpreted in the context of the server host, not the context of the host from which the job is submitted.

See the Authorized_Groups reservation attribute in section 6.8, “Reservation Attributes”, on page 303.

Syntax:

[+|-]<group name>[,[+|-]<group name> ...]

Default: No groups are authorized to submit jobs

--hosts <host list>

Space-separated list of hosts to be included in maintenance reservation. PBS creates placement and resource requests. Placement is always *exclhost*, and all CPUs of requested hosts are assigned to maintenance reservation. Cannot be used with the `-l <placement>`, `-l <resource request>`, or `-I <block time>` options.

-H <auth host list>

Comma-separated list of hosts from which jobs can and cannot be submitted to this reservation. This list becomes the acl_hosts list for the reservation's queue. More specific entries should be listed before more general, because the list is read left-to-right, and the first match determines access. If the reservation creator specifies this list, the creator's host is not automatically added to the list.

See the Authorized_Hosts reservation attribute in section 6.8, “Reservation Attributes”, on page 303.

Format: *[+|-]<hostname>[,[+|-]<hostname> ...]*

Default: All hosts are authorized to submit jobs

-I <block time>

Specifies interactive mode. The `pbs_rsub` command will block, up to *block time* seconds, while waiting for the reservation request to be confirmed or denied.

If *block time* is positive, and the reservation isn't confirmed or denied in the specified time, the ID string for the reservation is returned with the status "`UNCONFIRMED`".

If *block time* is negative, and a scheduler doesn't confirm or deny the reservation in the specified time, the reservation is deleted.

Cannot be used with `--hosts` option. Has no effect when used with `--job` option.

Format: *Integer*.

Default: *Not interactive*.

--job <job ID>

Immediately creates and confirms a *job-specific now reservation* on the same resources as the job (including resources inherited by the job), and places the job in the job-specific now reservation queue. Sets the job's create_resv_from_job attribute to *True*. Sets the now reservation's reserve_job attribute to the ID of the job from which the reservation was created, sets the reservation's Reserve_Owner attribute to the value of the job's Job_Owner attribute, sets the reservation's resv_nodes attribute to the job's exec_vnode attribute, sets the reservation's resources to match the job's schedselect attribute, and sets the reservation's Resource_List attribute to the job's Resource_List attribute.

The now reservation's duration and start time are the same as the job's walltime and start time. If the job is peer scheduled, the now reservation is created in the pulling complex.

Format: job ID

Default: no default

Example:

```
pbs_rsub --job 1234.myserver
```

Can be used on running jobs only (jobs in the *R* state, with substate *42*).

Cannot be used with job arrays, jobs already in reservations, or other users' jobs.

-l <placement>

The *placement* specifies how vnodes are reserved. The place statement can contain the following elements, in any order:

-l place=[<arrangement>][:[<sharing>]][:[<grouping>]]

where

arrangement

Whether this reservation chunk is willing to share this vnode or host with other chunks from this reservation. One of *free* | *pack* | *scatter* | *vscatter*

sharing

Whether this reservation chunk is willing to share this vnode or host with other reservations or jobs. One of *excl* | *shared* | *exclhost*

grouping

Whether the chunks from this reservation should be placed on vnodes that all have the same value for a resource. Can have only one instance of *group=<resource name>*

free

Place reservation on any vnode(s).

pack

All chunks are taken from one host.

scatter

Only one chunk with any MPI processes is taken from a host. A chunk with no MPI processes may be taken from the same vnode as another chunk.

vscatter

Only one chunk is taken from any vnode. Each chunk must fit on a vnode.

excl

Only this reservation uses the vnodes chosen.

shared

This reservation can share the vnodes chosen.

exclhost

The entire host is allocated to the reservation.

group=<resource name>

Chunks are grouped according to the specified resource. All vnodes in the group must have a common value for *resource*, which can be either the built-in resource host or a custom vnode-level resource.

Resource name must be a string or a string array.

If you want to run jobs in the reservation that will request exclusive placement, you must create the reservation with exclusive placement via `-l place=excl`.

The place statement cannot start with a colon. Colons are delimiters; use them only to separate parts of a place statement, unless they are quoted inside resource values.

Note that vnodes can have sharing attributes that override reservation placement requests.

See section 6.10, “Vnode Attributes”, on page 320.

Cannot be used with `--hosts` option.

-l <resource request>

The *resource request* specifies the resources required for the reservation. These resources are used for the limits on the queue that is dynamically created for the reservation. The aggregate amount of resources for currently running jobs from this queue will not exceed these resource limits. Jobs in the queue that request more of a resource than the queue limit for that resource are not allowed to run. Also, the queue inherits the value of any resource limit set on the server, and these are used for the job if the reservation request itself is silent about that resource. A non-privileged user cannot submit a reservation requesting a custom resource which has been created to be invisible or read-only for users.

Resources are requested by using the `-l` option, either in chunks inside of selection statements, or in job-wide requests using *<resource name>=<value>* pairs.

Requesting resources in chunks:

-l select=[N:]<chunk>[+[N:]<chunk> ...]

where *N* specifies how many of that chunk, and a chunk is of the form:

<resource name>=<value>[:<resource name>=<value> ...]

Requesting job-wide resources:

-l <resource name>=<value>[,<resource name>=<value> ...]

Default: One chunk containing one CPU.

Cannot be used with `--hosts` option.

-m <mail events>

Specifies the set of events that cause mail to be sent to the list of users specified in the `-M <mail list>` option.

Format: string consisting of one of the following:

- Any combination of "*a*", "*b*", "*c*" or "*e*"
- The single character "*n*"

The following table lists the sub-options to the -m option:

Table 2-5: Sub-options to -m Option

Character	Meaning
a	Notify if the reservation is terminated for whatever reason
b	Notify when the reservation period begins
c	Notify when the reservation is confirmed
e	Notify when the reservation period ends
n	Send no mail. Cannot be used with any of *a*, *b*, *c*, or *e*.

Default: "*ac*".

-M <mail list>

The list of users to whom mail is sent whenever the reservation transitions to one of the states specified in the `-m <mail events>` option.

Format: *<username>[@<hostname>][,<username>[@<hostname>]...]*

Default: Reservation owner.

-N <reservation name>

Specifies a name for the reservation.

Format: *Reservation Name*. See "Reservation Name" on page 358.

Default: None.

-q <server>

Specifies the server at which to create the reservation.

Default: Default server

-r <recurrence rule>

Specifies rule for recurrence of standing reservations. Rule must conform to iCalendar syntax, and is specified using a subset of parameters from RFC 2445.

Valid syntax for *recurrence rule* takes one of two forms:

FREQ=<freq spec>;COUNT=<count spec>;<interval spec>

or

FREQ=<freq spec>;UNTIL=<until spec>;<interval spec>

where

freq spec

Frequency with which the standing reservation repeats. Valid values are:

WEEKLY|DAILY|HOURLY

count spec

The exact number of occurrences. Number up to 4 digits in length.

Format: *Integer*.

interval spec

Specifies interval. Format is one or both of:

BYDAY=MO|TU|WE|TH|FR|SA|SU

or

BYHOUR=0|1|2|...|23

When using both, separate them with a semicolon.

Elements specified in the recurrence rule override those specified in the arguments to the -R and -E options. For example, the BYHOUR specification overrides the hourly part of the -R option. For example, `-R 0730 -E 0830 ... BYHOUR=9` results in a reservation that starts at 9:30 and runs for 1 hour.

until spec

Occurrences will start up to but not after date and time specified. Format:

<YYYYMMDD>[T<HHMMSS>]

Note that the year-month-day section is separated from the hour-minute-second section by a capital T.

Requirements:

- The recurrence rule must be on one unbroken line and must be enclosed in double quotes.
- A start and end date must be used when specifying a recurrence rule. See the R and E options.
- The PBS_TZID environment variable must be set at the submission host. The format for PBS_TZID is a timezone location. Examples: `America/Los_Angeles, America/Detroit, Europe/Berlin, Asia/Calcutta`. See the PBS Professional User's Guide.
- Spaces are not allowed.

Examples of Standing Reservations

For a reservation that runs every day from 8am to 10am, for a total of 10 occurrences:

```
pbs_rsub -R 0800 -E 1000 -r "FREQ=DAILY;COUNT=10"
```

Every weekday from 6am to 6pm until December 10 2008

```
pbs_rsub -R 0600 -E 1800 -r "FREQ=WEEKLY;BYDAY=MO,TU,WE,TH,FR;UNTIL=20081210"
```

Every week from 3pm to 5pm on Monday, Wednesday, and Friday, for 9 occurrences, i.e., for three weeks:

```
pbs_rsub -R 1500 -E 1700 -r "FREQ=WEEKLY;BYDAY=MO,WE,FR;COUNT=3"
```

-R <start time>

Specifies reservation starting time. If the reservation's end time and duration are the only times specified, this start time is calculated.

If the day, *DD*, is not specified, it defaults to today if the time *hhmm* is in the future. Otherwise, the day is set to tomorrow. For example, if you submit a reservation with the specification `-R 1110` at 11:15 a.m., it is interpreted as being for 11:10am tomorrow. If the month portion, *MM*, is not specified, it defaults to the current month, provided that the specified day *DD*, is in the future. Otherwise, the month is set to next month. Similar rules apply to the two other optional, left-side components.

Format: *Datetime*

-u <user list>

Not used. Comma-separated list of user names.

Format: *<username>[@<hostname>][,<username>[@<hostname>] ...]*

Default: None.

-U <auth user list>

Comma-separated list of users who are and are not allowed to submit jobs to this reservation. Sets reservation's Authorized_Users attribute to *auth user list*.

This list becomes the acl_users attribute for the reservation's queue.

More specific entries should be listed before more general, because the list is read left-to-right, and the first match determines access. The reservation creator's username is automatically added to this list, whether or not the reservation creator specifies this list.

If both the Authorized_Users and Authorized_Groups reservation attributes are set, a user must belong to both in order to be able to submit jobs to this reservation.

See the Authorized_Users reservation attribute in section 6.8, "Reservation Attributes", on page 303.

Syntax:

[+|-]<username>[@<hostname>][,[+|-]<username>[@<hostname>]...]

Default: Job owner only.

-W<extended options>

This allows you to define other attributes for the reservation or perform other actions.

delete_idle_time=<allowed idle time>

Deletes the reservation after the specified amount of idle time. Applies to each instance of a standing reservation.

The default value for the delete_idle_time attribute for an ASAP reservation is 10 minutes.

qmove=<job ID> [-I -<timeout>]

Takes as input a queued job, creates a *job-specific ASAP reservation* for the same resources the job requests, and moves the job into the reservation's queue. The reservation is scheduled to run as soon as possible.

When the reservation is created, it inherits its resources from the job, not from the resources requested through the `pbs_rsub` command.

You can use the `-I` option to specify a timeout for the conversion. If you use the `qmove` option to convert a job to a reservation, and the reservation is not confirmed within the timeout period, the reservation is deleted. The default timeout period is *10 seconds*. There is no option for this kind of reservation to be unconfirmed.

To specify the timeout, you must give a negative value for the `-I` option. For example, to specify a timeout of 300 seconds:

```
pbs_rsub -Wqmove=<job ID> -I -300
```

The default value for the delete_idle_time attribute for an ASAP reservation is 10 minutes.

The `-R` and `-E` options to `pbs_rsub` are disabled when using the qmove=<job ID> option.

Some shells require that you enclose a job array ID in double quotes.

Can be used on queued jobs only.

--version

The `pbs_rsub` command returns its PBS version information and exits. This option can only be used alone.

2.31.4 Output

The `pbs_rsub` command returns the reservation identifier.

Format for an advance or job-specific reservation:

R<sequence number>.<server name>

The associated queue's name is the prefix, *R<sequence number>*.

Format for a standing reservation:

S<sequence number>.<server name>

The associated queue's name is the prefix, *S<sequence number>*.

Format for a maintenance reservation:

M<sequence number>.<server name>

The PBS Professional User's Guide, the PBS Professional Administrator's Guide, "pbs_rstat" on page 94, "pbs_rdel" on page 90, "Reservation Attributes" on page 303

2.32 pbs_sched

Runs a PBS scheduler

2.32.1 Synopsis

pbs_sched [-a <alarm>] [-c <clientsfile>] [-d <home dir>] [-I <scheduler name>] [-L <logfile>] [-n] [-N] [-p <output file>] [-t <num threads>]

pbs_sched --version

2.32.2 Description

Runs the default scheduler or a multisched.

2.32.2.1 Required Permission

`pbs_sched` must be executed with root permission.

2.32.3 Options to `pbs_sched`

-c <clientsfile>

Add clients to this scheduler's list of known clients. The *clientsfile* contains single-line entries of the form

```
$clienthost <hostname>
```

Each *hostname* is added to the list of hosts allowed to connect to this scheduler. If *clientsfile* cannot be opened, this scheduler aborts. Path can be absolute or relative. If relative, it is relative to `PBS_HOME/sched_priv/`.

-d <home dir>

The directory in which this scheduler will run.

Default: `PBS_HOME/sched_priv`.

-I <scheduler name>

Name of scheduler to start. Required when starting a multisched.

-L <logfile>

The absolute path and filename of the log file. This scheduler writes its PBS version and build information to *logfile* whenever it starts up or *logfile* is rolled to a new file.

See the -d option.

Default: This scheduler opens a file named for the current date in the `PBS_HOME/sched_log` directory.

-n

Tells this scheduler to not restart itself if it receives a sigsegv or a sigbus. A scheduler by default restarts itself if it receives either of these two signals more than five minutes after starting. A scheduler does not restart itself if it receives either one within five minutes of starting.

-N

Runs the scheduler in standalone mode.

-p <output file>

Any output which is written to standard out or standard error is written to *output file*. The pathname can be absolute or relative, in which case it is relative to `PBS_HOME/sched_priv`.

See the -d option.

Default: `PBS_HOME/sched_priv/sched_out`

-t <num threads>

Specifies number of threads for this scheduler.

Scheduler automatically caps number of threads at the number of cores (or hyperthreads if applicable), regardless of value of *num threads*.

Overrides PBS_SCHED_THREADS environment variable and PBS_SCHED_THREADS parameter in `pbs.conf`.

Valid values: *>=1*

Default: one thread

--version

The `pbs_sched` command returns its PBS version information and exits. This option can only be used alone.

2.32.4 Signal Handling

All signals are ignored until the end of the cycle. Most signals are handled in the standard UNIX fashion.

SIGHUP

This scheduler closes and reopens its log file and rereads its configuration file if one exists.

SIGALRM, SIGBUS, etc.

Ignored until end of scheduling cycle. This scheduler quits.

SIGINT and SIGTERM

This scheduler closes its log file and shuts down.

All other signals have the default action installed.

2.32.5 Exit Status

Zero

Upon normal termination

2.32.6 See Also

The PBS Professional Administrator's Guide

2.33 pbs_server

Starts a PBS batch server

2.33.1 Synopsis

pbs_server [-A <acctfile>] [-a <active>] [-C] [-d <config path>] [-e <mask>] [-F <delay>] [-L <logfile>] [-M <MoM port>] [-N] [-p <port number>] [-R <MoM RM port>] [-s <replacement string>] [-t <restart type>]

pbs_server --version

2.33.2 Description

The `pbs_server` command starts a batch server on the local host. Typically, this command is in a local boot file such as `/etc/rc.local`. If the batch server is already running, `pbs_server` exits with an error.

2.33.2.1 Required Permission

To ensure that the `pbs_server` command is not runnable by the general user community, the server runs only if its real and effective UID is zero. You must be root.

2.33.3 Options to `pbs_server`

-A <acctfile>

Specifies an absolute path name for the file to use as the accounting file. If not specified, the file is named for the current date in the `PBS_HOME/server_priv/accounting` directory.

-a <value>

When *True*, the server is in state "*active*" and the default scheduler is called to schedule jobs. When *False*, the server is in state "*idle*" and the default scheduler is not called to schedule jobs. Sets the server's scheduling attribute. If this option is not specified, the server uses the previously specified *value* for the scheduling attribute.

Format: *Boolean*

-C

The server starts up, creates the database, and exits. Windows only.

-d <config path>

Specifies the absolute path to the directory containing the server configuration files, `PBS_HOME`. A host may have multiple servers. Each server must have a different configuration directory. The default configuration directory is specified in $PBS_HOME, and is typically `/var/spool/pbs`.

-e <mask>

Specifies a log event mask to be used when logging. See "log_events" in section 6.6, “Server Attributes”, on page 281.

-F <delay>

Specifies the number of seconds that the secondary server should wait before taking over when it believes the primary server is down. If the number of seconds is specified as *-1*, the secondary will make one attempt to contact the primary and then become active.

Default: *30 seconds*

-L <logfile>

Specifies the absolute path name for the log file. If not specified, the file is named for the current date in the PBS_HOME/server_logs directory. PBS_HOME is specified in the $PBS_HOME environment variable or in /etc/pbs.conf; see the -d option.

-M <MoM port>

Specifies the hostname and/or port number on which the server should connect to MoM. The option argument, *MoM port*, uses the syntax:

[<hostname>][:<port number>]

If *hostname* not specified, the local host is assumed.

If *port number* is not specified, the default port is assumed.

See the -M option in section 2.22, "pbs_mom", on page 71.

Default: *15002*

-N

Runs the server in standalone mode.

-p <port number>

Specifies the port number on which the server is to listen for batch requests. If multiple servers are running on a single host, each must have its own unique port number. This option is for testing with multiple batch systems on a single host.

Format: Integer port number

Default: *15001*

-R <MoM RM port>

Specifies the port number on which the server should query the up/down status of MoM. See the -R option in section 2.22, "pbs_mom", on page 71.

Default: *15003*

-s <replacement string>

Specifies the string to use when replacing spaces in accounting entity names. Only available under Windows.

-t <restart type>

Specifies behavior when the server restarts. The *restart type* argument is one of the following:

cold

All jobs are purged. Positive confirmation is required before this direction is accepted.

create

The server discards any existing configuration files: server, nodes, queues, and jobs, and initializes configuration files to the default values. The default scheduler is idled (scheduling is set to *False*). Any multischeds are deleted.

hot

All jobs in the *Running* state are retained in that state. Any job that was requeued into the *Queued* state from the *Running* state when the server last shut down is run immediately, assuming the required resources are available. This returns the server to the same state as when it went down. After those jobs are restarted, normal scheduling takes place for all remaining queued jobs. All other jobs are retained in their current state.

If a job cannot be restarted immediately because of a missing resource, such as a vnode being down, the server attempts to restart it periodically for up to 5 minutes. After that period, the server will revert to a normal state, as if *warm* started, and will no longer attempt to restart any remaining jobs which were running prior to the shutdown.

updatedb

Updates format of PBS data from the previous format to the data service format.

warm
All jobs in the *Running* state are retained in that state. All other jobs are maintained in their current state. The default scheduler typically chooses new jobs for execution. *warm* is the default if `-t` is not specified.

--version
The `pbs_server` command returns its PBS version information and exits. This option can only be used alone.

2.33.4 Files

`$PBS_HOME/server_priv`
Default directory for configuration files.

`$PBS_HOME/server_logs`
Directory for log files recorded by the server.

2.33.5 Signal Handling for pbs_server

When it receives the following signals, the server performs the following actions:

SIGHUP
The current server log and accounting log are closed and reopened. This allows for the prior log to be renamed and a new log started from the time of the signal.

SIGTERM
Causes a rapid orderly shutdown of `pbs_server`, identical to "`qterm -t quick`".

SIGSHUTDN
On systems where SIGSHUTDN is defined, causes an orderly "*quick*" shutdown of the server.

SIGPIPE, SIGUSR1, SIGUSR2
These signals are ignored.

All other signals have their default behavior installed.

2.33.6 Diagnostic Messages

The server records a diagnostic message in a log file for any error occurrence. The log files are maintained in the `server_logs` directory below the home directory of the server. If the log file cannot be opened, the diagnostic message is written to the system console. The server writes its PBS version and build information to the logfile whenever it starts up or the logfile is rolled to a new file.

2.33.7 Stopping the PBS Server

2.33.7.1 Stopping the Server on Linux

Use the `qterm` command (see section 2.58, “qterm”, on page 236):

```
qterm
```

or send a SIGTERM:

```
kill <server PID>
```

2.33.8 Exit Status

Zero

When the server has run in the background and then exits

Greater than zero

If the server daemon fails to begin batch operation

2.33.9 See Also

The *PBS Professional Administrator's Guide*

2.34 pbs_snapshot

Linux only. Captures PBS workload and configuration data

2.34.1 Synopsis

pbs_snapshot -h, --help

pbs_snapshot -o <output directory path> [--accounting-logs=<number of days>] [--additional-hosts=<hostname list>] [--basic] [--config-only] [--daemon-logs=<number of days>] [-H <server host>] [-l <log level>] [--map=<file path>] [--obfuscate] [--with-sudo]

pbs_snapshot [--obf-snap <path to snapshot>]

pbs_snapshot --version

2.34.2 Description

You use `pbs_snapshot` to capture PBS workload and configuration data. This tool is written in Python and uses PTL libraries, including `PBSSnapUtils`, to extract the data. You can optionally anonymize the PBS data during or after capturing it. The `pbs_snapshot` command captures data from all multischeds. The command detects which daemon or daemons are running on the host where it is collecting information, and captures daemon and system data accordingly. If no PBS daemons are running, the command collects system information. The output tarball contains information about the host specified via the `-H` option, or if that is not specified, the local host. If you specify additional hosts, the command creates a tarball for each additional host and includes it as a sub-tarball in the output.

- To supply information for simulation that you will use to tune your site, capture standard PBS configuration and node information via the `--basic` option.
- To supply information to PBS Cloud, capture PBS configuration file information via the `--config-only` option.
- For debugging your site, capture everything via the default behavior (do not specify `--basic` or `--config-only`).

2.34.2.1 Required Privilege

The `pbs_snapshot` command allows you to use the `sudo` infrastructure provided by the PTL framework to capture root-owned information via `--with-sudo`. All other information is collected as a normal user. If you need to run `pbs_snapshot` as a non-privileged user, and without using the PTL `--with-sudo` infrastructure, you must be root if you want root-owned information to be collected.

2.34.2.2 Restrictions

The `pbs_snapshot` command is not available on Windows.

2.34.3 Options to pbs_snapshot

--accounting-logs=<number of days>

Specifies number of days of accounting logs to be collected; this count includes the current day.

Value of *number of days* must be >=0:

- If number of days is 0, no logs are captured.
- If number of days is 1, only the logs for the current day are captured.

Default: `pbs_snapshot` collects 30 days of accounting logs

--additional-hosts=<hostname list>

Specifies that `pbs_snapshot` should gather data from the specified list of additional hosts. Launches the `pbs_snapshot` command on each specified host, creates a tarball there named *<hostname>_snapshot.tgz*, and includes it as a sub-tarball in the output for the main output. If you use the `--with-sudo` option, each launched copy uses that option as well.

The command does not query the server when it runs at a non-server host.

The command collects a full snapshot, including the following information:

- Daemon logs, for the number of days of logs being captured, specified via the `--daemon-logs=<number of days>` option
- The `PBS_HOME/<daemon>_priv` directory
- Accounting logs if server daemon runs on host
- System information

Format for *hostname list* is a comma-separated list of one or more hostnames:

<hostname>[, <hostname> ...]

--basic

Captures basic PBS configuration and node information only. Captures the following:

Table 2-6: PBS Configuration Information Captured with --basic Option

Directory or File	Output File	Description of Captured Information
pbs.conf		Copy of /etc/pbs.conf on server host
server	qstat_Bf.out	Output of qstat -Bf
	qstat_Qf.out	Output of qstat -Qf
server_priv	resourcedef	Copy of server_priv/resourcedef file
	config	Copy of server_priv/config file
scheduler	qmgr_lsched.out	Output of qmgr -c 'list sched'
sched_priv for each scheduler instance	sched_priv	Copy of each scheduler's sched_priv directory
hook	qmgr_lpbshook.out	Output of qmgr -c 'list pbshook'
	qmgr_ph_default.out	Output of qmgr -c 'print hook @default'
mom_priv on server host only, if it exists	config on server host only, if it exists	Copy of mom_priv/config file
node	pbsnodes_va.out	Output of pbsnodes -va
reservation	pbs_rstat_f.out	Output of pbs_rstat -f
job	qstat_f.out	Output of qstat -f
system	os_info	OS information
	pbs_environment	Copy of pbs_environment file
pbs_snapshot.log		Log of pbs_snapshot execution
ctime		Timestamp of when the snapshot was taken

Can be combined with other options such as --accounting_logs and --daemon_logs in order to capture additional information.

We also list the contents in section 2.34.4.2, “Output Contents”, on page 116.

--config-only

Captures PBS configuration file information only. Captures the following:

Table 2-7: PBS Configuration Information Captured with --config-only Option

Directory or File	Output File	Description of Captured Information
pbs.conf		Copy of /etc/pbs.conf on server host
server	qstat_Bf.out	Output of qstat -Bf
	qstat_Qf.out	Output of qstat -Qf
server_priv	resourcedef	Copy of server_priv/resourcedef file
	config	Copy of server_priv/config file
scheduler	qmgr_lsched.out	Output of qmgr -c 'list sched'
sched_priv for each scheduler instance	dedicated_time	Copy of dedicated_time file
	holidays	Copy of holidays file
	resource_group	Copy of resource_group file
	sched_config	Copy of sched_config file
hook	qmgr_lpbshook.out	Output of qmgr -c 'list pbshook'
	qmgr_ph_default.out	Output of qmgr -c 'print hook @default'
mom_priv only for server host, if it exists	config on server host only, if it exists	Copy of mom_priv/config file
system	os_info	OS information
	pbs_environment	Copy of pbs_environment file
pbs_snapshot.log		Log of pbs_snapshot execution
ctime		Timestamp of when the snapshot was taken

Can be combined with other options such as --accounting_logs and --daemon_logs in order to capture additional information.

We also list the contents in section 2.34.4.2, “Output Contents”, on page 116.

--daemon-logs=<number of days>

Specifies number of days of daemon logs to be collected; this count includes the current day.

Value of *number of days* must be >=0:

- If number of days is 0, no logs are captured.
- If number of days is 1, only the logs for the current day are captured.

Default: pbs_snapshot collects 5 days of daemon logs

-h, --help

Prints usage and exits.

-H <hostname>

Specifies hostname for host whose retrieved data is to be at the top level in the output tarball. If not specified, pbs_snapshot puts data for the local host at the top level in the output tarball.

-l <log level>

Specifies level at which pbs_snapshot writes its log. The log file is pbs_snapshot.log, in the output directory path specified using the -o <output directory path> option.

Valid values, from most comprehensive to least: *DEBUG2, DEBUG, INFOCLI2*, *INFOCLI, INFO*, *WARNING*, *ERROR*, *FATAL*

Default: *INFOCLI2*

--map=<file path>

Specifies path for file containing obfuscation map, which is a <key>:<value> pair-mapping of obfuscated data. Path can be absolute or relative to current working directory.

Default: pbs_snapshot writes its obfuscation map in a file called "obfuscate.map" in the location specified via the -o <output directory path> option.

Can only be used with the --obfuscate option.

-o <output directory path>

Path to directory where pbs_snapshot writes its output tarball. Required. Path can be absolute or relative to current working directory.

For example, if you specify "-o /tmp", pbs_snapshot writes "/tmp/snapshot_<timestamp>.tgz".

The output directory path must already exist.

--obfuscate

Obfuscates (anonymizes) or deletes sensitive PBS data being captured by pbs_snapshot.

- Obfuscates the following data: euser, egroup, project, Account_Name, operators, managers, group_list, Mail_Users, User_List, server_host, acl_groups, acl_users, acl_resv_groups, acl_resv_users, sched_host, acl_resv_hosts, acl_hosts, Job_Owner, exec_host, Host, Mom, resources_available.host, resources_available.vnode
- Deletes the following data: Variable_List, Error_Path, Output_Path, mail_from, Mail_Points, Job_Name, jobdir, Submit_arguments, Shell_Path_List

--obf-snap <path to snapshot>

Obfuscates (anonymizes) or deletes sensitive PBS data already captured in an existing snapshot. Path can be a snapshot .tar file previously generated by pbs_snapshot, or a directory created by untarring a snapshot. Obfuscated snapshot is created with the name "<directory or original snapshot>_obf.tgz".

- Obfuscates the following data: euser, egroup, project, Account_Name, operators, managers, group_list, Mail_Users, User_List, server_host, acl_groups, acl_users, acl_resv_groups, acl_resv_users, sched_host, acl_resv_hosts, acl_hosts, Job_Owner, exec_host, Host, Mom, resources_available.host, resources_available.vnode
- Deletes the following data: Variable_List, Error_Path, Output_Path, mail_from, Mail_Points, Job_Name, jobdir, Submit_arguments, Shell_Path_List

If the snapshot contains snapshots of multiple hosts, each snapshot must be obfuscated individually.

--version

The pbs_snapshot command prints its PBS version information and exits. Can only be used alone.

--with-sudo

Uses the PTL sudo infrastructure in order capture root-owned information via sudo. (Information not owned by root is captured using normal privilege, not root privilege.) With this option, you do not need to prefix your pbs_snapshot command with sudo, and you do not need root privilege.

2.34.4 Output

2.34.4.1 Output Location

You must use the `-o <output directory path>` option to specify the directory where `pbs_snapshot` writes its output. The path can be absolute or relative to current working directory. The output directory must already exist. As an example, if you specify "`-o /tmp`", `pbs_snapshot` writes "`/tmp/snapshot_<timestamp>.tgz`".

2.34.4.2 Output Contents

The `pbs_snapshot` command writes the output for the local host and each specified remote host as a tarball. Tarballs for remote hosts are included in the main tarball.

The command captures JSON output from `qstat -f -F json` and `pbsnodes -av -F json`.

The main tarball contains the following directory structure, files, and tarballs, and lists which of those elements appear in a tarball produced by the --basic and --config-only options:

Table 2-8: Contents of Snapshot

Directory or File	Directory Contents	Description	In Basic	In Config Only
server/	qstat_B.out	Output of `qstat -B`		
	qstat_Bf.out	Output of `qstat -Bf`	Yes	Yes
	qmgr_ps.out	Output of `qmgr print server`		
	qstat_Q.out	Output of `qstat -Q`		
	qstat_Qf.out	Output of `qstat -Qf`	Yes	Yes
	qmgr_pr.out	Output of `qmgr print resource`		
server_priv/	Copy of the `PBS_HOME/server_priv` directory. Core files are captured separately; see `core_file_bt/`.		`resourcedef`	`resourcedef` `config`
	accounting/	Accounting logs from `PBS_HOME/server_priv/accounting/` directory for the number of days specified via `--accounting-logs` option		
server_logs/	Server logs from the `PBS_HOME/server_logs` directory for the number of days specified via `--daemon-logs` option			

Table 2-8: Contents of Snapshot

Directory or File	Directory Contents	Description	In Basic	In Config Only
job/	qstat.out	Output of qstat		
	qstat_f.out	Output of qstat -f	Yes	
	qstat_f_F_json.out	Output of qstat -f -F json		
	qstat_t.out	Output of qstat -t		
	qstat_tf.out	Output of qstat -tf		
	qstat_x.out	Output of qstat -x		
	qstat_xf.out	Output of qstat -xf		
	qstat_ns.out	Output of qstat -ns		
	qstat_fx_F_dsv.out	Output of qstat -fx -F dsv		
	qstat_f_F_dsv.out	Output of qstat -f -F dsv		
node/	pbsnodes_va.out	Output of pbsnodes -va	Yes	
	pbsnodes_a.out	Output of pbsnodes -a		
	pbsnodes_avSj.out	Output of pbsnodes -avSj		
	pbsnodes_aSj.out	Output of pbsnodes -aSj		
	pbsnodes_avS.out	Output of pbsnodes -avS		
	pbsnodes_aS.out	Output of pbsnodes -aS		
	pbsnodes_aFdsv.out	Output of pbsnodes -aF dsv		
	pbsnodes_avFdsv.out	Output of pbsnodes -avF dsv		
	pbsnodes_avFjson.out	Output of pbsnodes -avF json		
	qmgr_pn_default.out	Output of qmgr print node @default		
mom_priv/	Copy of the PBS_HOME/mom_priv directory. Core files are captured separately; see core_file_bt/.			mom_priv/config, only from server host
mom_logs/	MoM logs from the PBS_HOME/mom_logs directory for the number of days specified via --daemon-logs option			
comm_logs/	Comm logs from the PBS_HOME/comm_logs directory for the number of days specified via --daemon-logs option			
sched_priv/	Copy of the PBS_HOME/sched_priv directory, with all files. Core files are not captured; see core_file_bt/.		Yes	
sched_logs/	Scheduler logs from the PBS_HOME/sched_log directory. For a snapshot of a live PBS complex, this is for the number of days specified via pbs_snapshot --daemon-logs. For a simulation output snapshot, this is for the time simulated via simsh <path to snapshot> sim -L.			

Table 2-8: Contents of Snapshot

Directory or File	Directory Contents	Description	In Basic	In Config Only
sched_priv_<multisched name>/	Copy of the PBS_HOME/sched_priv_<multisched name> directory, with all files. Core files are not captured; see core_file_bt/.		Yes	dedicated_time holidays resource_group sched_config
sched_logs_<multisched name>/	Multisched logs from the PBS_HOME/sched_log_<multisched name> directory for the number of days specified via --daemon-logs option			
reservation/	pbs_rstat_f.out	Output of pbs_rstat -f	Yes	
	pbs_rstat.out	Output of pbs_rstat		
scheduler/	qmgr_lsched.out	Output of qmgr list sched	Yes	Yes
hook/	qmgr_ph_default.out	Output of qmgr -c 'print hook @default'		Yes
	qmgr_lpbshook.out	Output of qmgr -c 'list pbshook'	Yes	Yes
datastore/	pg_log/	Copy of the PBS_HOME/datastore/pg_log directory for the number of days specified via --daemon-logs option		

Table 2-8: Contents of Snapshot

Directory or File	Directory Contents	Description	In Basic	In Config Only
core_file_bt/	Stack backtrace from core files			
	sched_priv/	Files containing the output of `thread apply all backtrace full` on all core files captured from PBS_HOME/sched_priv		
	sched_priv_<multi-sched name>	Files containing the output of `thread apply all backtrace full` on all core files captured from PBS_HOME/sched_priv_<multisched name>		
	server_priv/	Files containing the output of `thread apply all backtrace full` on all core files captured from PBS_HOME/server_priv		
	mom_priv/	Files containing the output of `thread apply all backtrace full` on all core files captured from PBS_HOME/mom_priv		
	misc/	Files containing the output of `thread apply all backtrace full` on any other core files found inside PBS_HOME		

Table 2-8: Contents of Snapshot

Directory or File	Directory Contents	Description	In Basic	In Config Only
system/	pbs_probe_v.out	Output of pbs_probe -v		
	pbs_hostn_v.out	Output of pbs_hostn -v $(hostname)		
	pbs_environment	Copy of PBS_HOME/pbs_environment file		Yes
	os_info	Information about the OS		Yes
	process_info	List of processes running on the system when the snapshot was taken. Output of ps -aux | grep [p]bs on Linux systems, or tasklist /v on Windows systems		
	ps_leaf.out	Output of ps -leaf. Linux only.		
	lsof_pbs.out	Output of lsof | grep [p]bs. Linux only.		
	etc_hosts	Copy of /etc/hosts file. Linux only.		
	etc_nsswitch_conf	Copy of /etc/nsswitch.conf file. Linux only.		
	vmstat.out	Output of the command vmstat. Linux only.		
	df_h.out	Output of the command df -h. Linux only.		
	dmesg.out	Output of the dmesg command. Linux only.		
pbs.conf	Copy of the pbs.conf file on the server host		Yes	Yes
ctime	Contains the time in seconds since epoch when the snapshot was taken		Yes	Yes
pbs_snapshot.log	Log messages written by pbs_snapshot		Yes	Yes
<remote hostname>.tgz	Tarball of output from running the pbs_snapshot command at a remote host			

2.34.5 Examples

pbs_snapshot -o /tmp

Writes a snapshot to /tmp/snapshot_<timestamp>.tgz that includes 30 days of accounting logs and 5 days of daemon logs from the server host.

pbs_snapshot --daemon-logs=1 --accounting-logs=1 -o /tmp --obfuscate --map=mapfile.txt

Writes a snapshot to /tmp/snapshot_<timestamp>.tgz that includes 1 day of accounting and daemon logs. Obfuscates the data and stores the data mapping in the map file named "mapfile.txt".

2.35 pbs_tclsh

Deprecated. TCL shell with TCL-wrapped PBS API

2.35.1 Synopsis

pbs_tclsh

pbs_tclsh --version

2.35.2 Description

The `pbs_tclsh` command starts a version of the TCL shell which includes wrapped versions of the PBS external API. The PBS TCL API is documented in "TCL/tk Interface" on page 105 in the PBS Professional Programmer's Guide.

The `pbs_tclsh` command is used to query MoM. For example:

```
> pbs_tclsh
tclsh> openrm <hostname>
<file descriptor>
tclsh> addreq <file descriptor> "loadave"
tclsh> getreq <file descriptor>
<load average>
tclsh> closereq <file descriptor>
```

2.35.2.1 Required Permission

Root privilege is required in order to query MoM for dynamic resources. Root privilege is not required in order to query MoM for built-in resources and site-defined static resources.

2.35.3 Options

--version

The `pbs_tclsh` command returns its PBS version information and exits. This option can only be used alone.

2.35.4 Standard Error

The `pbs_tclsh` command writes a diagnostic message to standard error for each error occurrence.

2.35.5 See Also

The PBS Professional Administrator's Guide, the PBS Programmer's Guide, "pbs_wish" on page 127

2.36 pbs_tmrsh

TM-enabled replacement for `rsh/ssh` for use by MPI implementations

2.36.1 Synopsis

pbs_tmrsh <hostname> [-l <username>] [-n] <command> [<args> ...]

pbs_tmrsh --version

2.36.2 Description

The `pbs_tmrsh` command attempts to emulate an "`rsh`" connection to the specified host, via underlying calls to the Task Management (TM) API. The program is intended to be used during MPI integration activities, and not by end-users.

Running "`pbs_tmrsh` <hostname> `<command>`" causes a PBS task to be started on *hostname* running *command*.

2.36.2.1 Requirements for Environment Variables

The environment variables used by the two MPI implementations to point to the `rsh` work-alike (MPI_REMSH in the case of HP and P4_RSHCOMMAND for MPICH) must be set in the job environment and point to the full path for `pbs_tmrsh`.

The file `$PBS_HOME/pbs_environment` should contain the environment variable PATH in which to search for the program executable. This applies to both Windows and Linux. It is expected that a full path will be specified for the *command* and the PATH variable will not be needed.

2.36.3 Options

-l <username>
: Specifies the username under which to execute the task. If used, *username* must match the username running the `pbs_tmrsh` command.

-n
: A no-op; provided for MPI implementations that expect to call `rsh` with the "`-n`" option.

--version
: The `pbs_tmrsh` command returns its PBS version information and exits. This option can only be used alone.

2.36.4 Operands

command
: Specifies command to be run as a PBS task.

hostname
: Specifies host on which to run PBS task. The *hostname* may be specified in IP-dot-address form.

2.36.5 Output and Error

Output and errors are written to the PBS job's output and error files, not to standard output/error.

The pbs_tmrsh command writes a diagnostic message to the PBS job's error file for each error occurrence.

2.36.6 Exit Status

The pbs_tmrsh program exits with the exit status of the remote command or with *255* if an error occurred. This is because ssh works this way.

2.36.7 See Also

The PBS Professional Administrator's Guide, "pbs_attach" on page 56, "TM Library Routines", on page 95 of the PBS Professional Programmer's Guide

2.37 pbs_topologyinfo

Reports topological information

2.37.1 Synopsis

pbs_topologyinfo (-a | --all) [(-l | --license) | (-s | --sockets)]

pbs_topologyinfo (-l | --license) <vnode name> [<vnode name> ...]

pbs_topologyinfo (-s | --sockets) <vnode name> [<vnode name> ...]

pbs_topologyinfo -h | --help

2.37.2 Description

The `pbs_topologyinfo` command reports topological information for one or more vnodes. This information is used for licensing purposes. To use the command, you must specify what kind of topological information you want. The command reports only the requested information.

This command must be run on the server host.

2.37.2.1 Usage

`pbs_topologyinfo -al` reports number of node licenses needed for all vnodes.

`pbs_topologyinfo -l <vnode name>` reports number of node licenses needed for *vnode name*.

`pbs_topologyinfo -as` reports socket counts for all vnodes that have reported sockets.

`pbs_topologyinfo -s <vnode name>` reports socket count for vnode *vnode name*.

2.37.2.2 Prerequisites

Before you use this command, the server and MoMs must be configured so that they can contact each other, and must have been run.

2.37.2.3 Required Privilege for `pbs_topologyinfo`

This command can be run only by root or Admin on Windows.

2.37.3 Options for `pbs_topologyinfo`

-a, --all

Reports requested topological information for all vnodes. When this option is used alone, the command does not report any information.

-h, --help

Prints usage and exits.

-l, --license [<vnode name(s)>]

Reports number of node licenses required. If you specify *vnode name(s)*, the command reports node licenses needed for the specified vnode(s) only.

-s, --sockets [<vnode name(s)>]

Reports derived socket counts. If you specify *vnode name(s)*, the command reports socket count information for the specified vnode(s) only.

(no options)

Does not report any information.

2.37.4 Errors

If you specify an invalid vnode name, the command prints a message to standard error.

2.37.5 Operands

vnode name [<vnode name> ...]

Name(s) of vnode(s) about which to report.

2.37.6 Exit Status

0

Success

1

Any error following successful command line processing

2.37.7 Standard Error

If an invalid vnode name is specified, a message is printed to standard error.

2.37.8 See Also

The PBS Professional Administrator's Guide

2.38 pbs_wish

Deprecated. TK window shell with TCL-wrapped PBS API

2.38.1 Synopsis

pbs_wish

pbs_wish --version

2.38.2 Description

The `pbs_wish` command is a version of the TK window shell which includes wrapped versions of the PBS external API. The PBS TCL API is documented in "TCL/tk Interface" on page 105 in the PBS Professional Programmer's Guide.

2.38.3 Options

--version

The `pbs_wish` command returns its PBS version information and exits. This option can only be used alone.

2.38.4 Standard Error

The `pbs_wish` command writes a diagnostic message to standard error for each error occurrence.

2.38.5 See Also

The PBS Professional Administrator's Guide, "pbs_tclsh" on page 122

2.39 printjob

Prints job information

2.39.1 Synopsis

printjob [-a | -s] <job ID>

printjob [-a] <file path> [<file path>...]

printjob --version

2.39.2 Description

Prints job information. This command is mainly useful for troubleshooting, as during normal operation, the "qstat" command is the preferred method for displaying job-specific data and attributes. The server and MoM do not have to be running to execute this command.

2.39.2.1 Usage

For a running job, you can run this command at any host using a job ID, and you can run this command at any execution host where the job is running using a .JB file path.

For a finished job, if job history is enabled, you can run this command at the server using the job ID.

When querying the server, you must use the job ID, and the data service must be running.

Results will vary depending on whether you use the job ID or a .JB file, and on which execution host you query with a .JB file.

2.39.2.2 Permissions

In order to execute `printjob`, you must have root or Windows Administrator privilege.

2.39.3 Options to `printjob`

(no options>
: Prints all job data including job attributes.

-a
: Suppresses the printing of job attributes. Cannot be used with `-s` option.

-s
: Prints out the job script only. Can be used at server or primary execution host. Cannot be used with `-a` option. Must be used with a job ID.

--version
: The `printjob` command returns its PBS version information and exits. This option can only be used alone.

2.39.4 Operands for `printjob`

file path

The `printjob` command accepts one or more *file path* operands at the execution host. Files are found in `PBS_HOME/mom_priv/jobs/` on the primary execution host. File path must include full path to file. Cannot be used with `-s` option.

job ID

The `printjob` command accepts a *job ID* at the server host. The format is described in "Job ID, Job Identifier" on page 355. Data service must be running.

2.39.5 Standard Error

The `printjob` command writes a diagnostic message to standard error for each error occurrence.

2.39.6 Exit Status

Zero

Upon successful processing of all operands presented

Greater than zero

If the `printjob` command fails to process any operand

2.39.7 See Also

The PBS Professional Administrator's Guide, "qstat" on page 200

2.40 qalter

Alters a PBS job

2.40.1 Synopsis

qalter [-a <date and time>] [-A <account string>] [-c <checkpoint spec>] [-e <error path>] [-h <hold list>] [-j <join>] [-k <discard>] [-l <resource list>] [-m <mail events>] [-M <user list>] [-N <name>] [-o <output path>] [-p <priority>] [-P <project>] [-r <y|n>] [-R <remove options>] [-S <path list>] [-u <user list>] [-W <additional attributes>] <job ID> [<job ID> ...]

qalter --version

2.40.2 Description

The `qalter` command is used to alter one or more PBS batch jobs. Each of certain job attributes can be modified using the `qalter` option for that attribute. You can alter a job or a job array, but not a subjob or range of subjobs.

2.40.2.1 Required Privilege

A non-privileged user can alter their own jobs, whether they are queued or running. An Operator or Manager can alter any job, whether it is queued or running.

A non-privileged user can only lower resource requests. An Operator or Manager can raise or lower resource requests.

2.40.2.2 Modifying Resources and Job Placement

A Manager or Operator may lower or raise requested resource limits, except for per-process limits such as pcput and pmem, because these are set when the process starts, and enforced by the kernel. A non-privileged user can only lower resource requests.

The `qalter` command cannot be used by a non-privileged user to alter a custom resource which has been created to be invisible or read-only for users.

If a job is running, the only resources that can be modified are cput, walltime, min_walltime, and max_walltime.

If a job is queued, any resource mentioned in the options to the `qalter` command can be modified, but requested modifications must fit within the limits set at the server and queue for the amount of each resource allocated for queued jobs. If a requested modification does not fit within these limits, the modification is rejected.

A job's resource request must fit within the queue's and server's resource run limits. If a modification to a resource exceeds the amount of the resource allowed by the queue or server to be used by running jobs, the job is never run.

Requesting resources includes setting limits on resource usage and controlling how the job is placed on vnodes.

See Chapter 5, "List of Built-in Resources", on page 259.

2.40.2.2.i Syntax for Modifying Resources and Job Placement

Resources are modified by using the `-l` option, either in chunks inside of selection statements, or in job-wide requests using *<resource name>=<value>* pairs. The selection statement is of the form:

-l select=[<N>:]<chunk>[+[<N>:]<chunk> ...]

where *N* specifies how many of that chunk, and a *chunk* is of the form:

<resource name>=<value>[:<resource name>=<value> ...]

Job-wide <*resource name*>=<*value*> requests are of the form:

-l <resource name>=<value>[,<resource name>=<value> ...]

2.40.2.2.ii The Place Statement

You choose how your chunks are placed using the *place statement*. The *place statement* can contain the following elements, in any order:

-l place=[<arrangement>][: <sharing>][: <grouping>]

where

arrangement

Whether this chunk is willing to share this vnode or host with other chunks from the same job. One of *free* | *pack* | *scatter* | *vscatter*

sharing

Whether this this chunk is willing to share this vnode or host with other jobs. One of *excl* | *shared* | *exclhost*

grouping

Whether the chunks from this job should be placed on vnodes that all have the same value for a resource. Can have only one instance of *group=<resource name>*

free

Place job on any vnode(s).

pack

All chunks are taken from one host.

scatter

Only one chunk with any MPI processes is taken from a host. A chunk with no MPI processes may be taken from the same vnode as another chunk.

vscatter

Only one chunk is taken from any vnode. Each chunk must fit on a vnode.

excl

Only this job uses the vnodes chosen.

shared

This job can share the vnodes chosen.

exclhost

The entire host is allocated to the job.

group=<resource name>

Chunks are grouped according to a resource. All vnodes in the group must have a common value for *resource*, which can be either the built-in resource host or a custom vnode-level resource. The *resource name* must be a string or a string array.

The *place statement* cannot begin with a colon. Colons are delimiters; use them only to separate parts of a place statement, unless they are quoted inside resource values.

Note that vnodes can have sharing attributes that override job placement requests. See section 6.10, “Vnode Attributes”, on page 320.

For more on resources, resource requests, usage limits, and job placement, see "Using PBS Resources" on page 227 in the PBS Professional Administrator’s Guide and "Allocating Resources & Placing Jobs", on page 51 of the PBS Professional User’s Guide.

2.40.2.3 Modifying Attributes

The user alters job attributes via options to the `qalter` command. Each `qalter` option changes a job attribute.

The behavior of the `qalter` command may be affected by any site hooks. Site hooks can modify the job's attributes, change its routing, etc.

To modify the max_run_subjobs attribute, use `qalter -Wmax_run_subjobs=<new value> <job ID>`.

2.40.2.4 Caveats and Restrictions for Altering Jobs

- When you lengthen the walltime of a running job, make sure that the new walltime will not interfere with any existing reservations etc.
- If any of the modifications to a job fails, none of the job's attributes is modified.
- A job that is in the process of provisioning cannot be altered.

2.40.3 Options to `qalter`

-a <date and time>

Changes the point in time after which the job is eligible for execution. Given in pairs of digits. Sets job's Execution_Time attribute to *date and time*.

Format: *Datetime*

Each portion of the date defaults to the current date, as long as the next-smaller portion is in the future. For example, if today is the 3rd of the month and the specified day *DD* is the 5th, the month *MM* is set to the current month.

If a specified portion has already passed, the next-larger portion is set to one after the current date. For example, if the day *DD* is not specified, but the hour *hh* is specified to be 10:00 a.m. and the current time is 11:00 a.m., the day *DD* is set to tomorrow.

The job's Execution_Time attribute can be altered after the job has begun execution, in which case it will not take effect until the job is rerun.

-A <account string>

Replaces the accounting string associated with the job. Used for labeling accounting data. Sets job's Account_Name attribute to *account string*. This attribute cannot be altered once the job has begun execution.

Format: *String*

-c <checkpoint spec>

Changes when the job will be checkpointed. Sets job's Checkpoint attribute. An $action script is required to checkpoint the job. This attribute can be altered after the job has begun execution, in which case the new value will not take effect until the job is rerun.

The argument *checkpoint spec* can take one of the following values:

c

Checkpoint at intervals, measured in CPU time, set on job's execution queue. If no interval set at queue, job is not checkpointed.

c=<minutes of CPU time>

Checkpoint at intervals of specified number of minutes of job CPU time. This value must be greater than zero. If interval specified is less than that set on job's execution queue, queue's interval is used.

Format: *Integer*

w

Checkpoint at intervals, measured in walltime, set on job's execution queue. If no interval set at queue, job is not checkpointed.

w=<minutes of walltime>
Checkpoint at intervals of the specified number of minutes of job walltime. This value must be greater than zero. If the interval specified is less that that set on the job's execution queue, the queue's interval is used.

Format: *Integer*

n
No checkpointing.

s
Checkpoint only when the server is shut down.

u
Unset. Defaults to behavior when interval argument is set to s.

Default: *u*

Format: *String*

-e <error path>

Replaces the path to be used for the job's standard error stream. Sets job's Error_Path attribute to *error path*. Overridden by -k option.

Format: *[<hostname>:]<path>*

The *error path* is interpreted as follows:

path

If *path* is relative, it is taken to be relative to the current working directory of the `qalter` command, where it is executing on the current host.

If *path* is absolute, it is taken to be an absolute path on the current host where the `qalter` command is executing.

hostname:path

If *path* is relative, it is taken to be relative to the user's home directory on the host named *hostname*.

If *path* is absolute, it is the absolute path on the host named *hostname*.

If *path* does not include a filename, the default filename is *<job ID>.ER*

If the -e option is not specified, PBS writes standard error to the default filename, which has this form:

<job name>.e<sequence number>

This attribute can be altered after the job has begun execution, in which case the new value will not take effect until the job is rerun.

If you use a UNC path, the hostname is optional. If you use a non-UNC path, the hostname is required.

-h <hold list>

Updates the job's hold list. Adds *hold list* to the job's Hold_Types attribute. The *hold list* is a string of one or more characters. The following table shows the holds and the privilege required to set each:

Table 2-9: Hold Types

Hold Type	Meaning	Who Can Set
u	*User*	*Job owner, Operator, Manager, administrator, root*
o	*Other*	*Operator, Manager, administrator, root*
s	*System*	*Manager, administrator, root, PBS (dependency)*
n	*None*	*Job owner, Operator, Manager, administrator, root*
p	*Bad password*	*Administrator, root*

This attribute can be altered after the job has begun execution, in which case the new value will not take effect until the job is rerun.

-j <join>

Changes whether and how to join the job's standard error and standard output streams. Sets job's Join_Path attribute to *join*.

This attribute can be altered after the job has begun execution, in which case the new value will not take effect until the job is rerun.

Default: *n*; not merged

The *join* argument can take the following values:

Table 2-10: Join Path Options

Value	Meaning
oe	Standard error and standard output are merged into standard output.
eo	Standard error and standard output are merged into standard error.
n	Standard error and standard output are not merged.

-k <discard>

Specifies whether and which of the standard output and standard error streams is left behind on the execution host, or written to their final destination. Sets the job's Keep_Files attribute to *discard*.

k {e | o | eo | oe | n}

For the e, o, eo, oe, or n suboptions, overrides -o and -e options.

kd {e | o | eo | oe}

When used with the -d suboption, specifies that output and/or error files are written directly to the final destination. Requires -o <output path> and/or -e <error path>.

Default: *n*; neither is retained, and files are not written directly to final destinations.

In the case where output and/or error is retained on the execution host in a job-specific staging and execution directory created by PBS, these files are deleted when PBS deletes the directory.

The *discard* argument can take the following values:

Table 2-11: Sub-options to discard Option

Suboption	Meaning
e	The standard error stream is retained on the execution host, in the job's staging and execution directory. The filename is *<job name>.e<sequence number>*
o	The standard output stream is retained on the execution host, in the job's staging and execution directory. The filename is *<job name>.o<sequence number>*
eo, oe	Both standard output and standard error streams are retained on the execution host, in the job's staging and execution directory.
d<e and/or o>	Output and/or error are written directly to their final destination. Overrides action of leaving files on execution host. Requires -o <output path> and/or -e <error path>.
n	Neither stream is retained.

-l <resource list>

Allows the user to change requested resources and job placement. Sets job's Resource_list attribute to *resource list*. Uses resource request syntax. Requesting a resource places a limit on its usage. Users without manager or operator privilege cannot alter a custom resource which was created to be invisible or read-only for users. For syntax, see section 2.40.2.2.i, “Syntax for Modifying Resources and Job Placement”, on page 130.

If a requested modification to a resource would exceed the server's or the job queue's limits, the resource request is rejected. Which resources can be altered is system-dependent.

If the job was submitted with an explicit "-l select=", vnode-level resources must be qaltered using the "-l select=" form. In this case a vnode-level resource *resource* cannot be qaltered with the "-l <resource name>" form.

The place statement cannot begin with a colon.

Examples:

1. Submit the job:

```
% qsub -l select=1:ncpus=2:mem=512mb jobscript
```

Job's ID is 230

2. qalter the job using "-l <resource name>" form:

```
% qalter -l ncpus=4 230
```

Error reported by qalter:

```
qalter: Resource must only appear in "select" specification when select is used: ncpus 230
```

3. qalter the job using the "-l select=" form:

```
% qalter -l select=1:ncpus=4:mem=512mb 230
```

No error reported by `qalter`:

```
%
```

For more on resource requests, usage limits and job placement, see "Allocating Resources & Placing Jobs", on page 51 of the PBS Professional User's Guide.

-m <mail events>

Changes the set of conditions under which mail about the job is sent. Sets job's Mail_Points attribute to *mail events*. The *mail events* argument can be one of the following:

- The single character "*n*"
- Any combination of "*a*", "*b*", and "*e*", with optional "*j*"

The following table lists the sub-options to the `-m` option:

Table 2-12: Sub-options to m Option

Suboption	Meaning
n	No mail is sent.
a	Mail is sent when the job is aborted by PBS.
b	Mail is sent when the job begins execution.
e	Mail is sent when the job terminates.
j	Mail is sent for subjobs. Must be combined with one or more of a, b, or e options

Can be used with job arrays but not subjobs.

Format: *String*

Syntax: *n | [j](one or more of a, b, e)*

Example: -m ja

Default value: *"a"*

-M <user list>

Alters list of users to whom mail about the job is sent. Sets job's Mail_Users attribute to *user list*.

Format: *<username>[@<hostname>][,<username>[@<hostname>],...]*

Default: Job owner.

-N <name>

Renames the job. Sets job's Job_Name attribute to *name*.

Format: *Job Name*. See "Job Name, Job Array Name" on page 355.

Default: if a script is used to submit the job, the job's name is the name of the script. If no script is used, the job's name is "*STDIN*".

-o <output path>

Alters path to be used for the job's standard output stream. Sets job's Output_Path attribute to *output path*. Overridden by `-k` option.

Format: *[<hostname>:]<path>*

The *output path* is interpreted as follows:

path

If *path* is relative, it is taken to be relative to the current working directory of the command, where it is executing on the current host.

If *path* is absolute, it is taken to be an absolute path on the current host where the command is executing.

<hostname>:<path>

If *path* is relative, it is taken to be relative to the user's home directory on the host named *hostname*.

If *path* is absolute, it is the absolute path on the host named *hostname*.

If *path* does not include a filename, the default filename is:

<job ID>.OU

If the -o option is not specified, PBS writes standard output to the default filename, which has this form:

<job name>.o<sequence number>

This attribute can be altered after the job has begun execution, in which case the new value will not take effect until the job is rerun.

If you use a UNC path, the hostname is optional. If you use a non-UNC path, the hostname is required.

-p <priority>

Alters priority of the job. Sets job's Priority attribute to *priority*.

This attribute can be altered after the job has begun execution, in which case the new value will not take effect until the job is rerun.

Format: *Host-dependent integer*

Range: [*-1024, +1023*] inclusive

Default: *zero*

-P <project>

Specifies a project for the job. Sets job's project attribute to specified value.

Format: *Project Name*; see "Project Name" on page 357

Default: "*_pbs_project_default*"

-r <y|n>

Changes whether the job is rerunnable. Sets job's Rerunable attribute to the argument. Does not affect how job is handled when the job is unable to begin execution.

See "qrerun" on page 181.

Format: Single character, "*y*" or "*n*".

y
: Job is rerunnable.

n
: Job is not rerunnable.

Default: "*y*".

Interactive jobs are not rerunnable. Job arrays are always rerunnable.

-R <remove options>

Changes whether standard output and/or standard error files are automatically removed upon job completion.

Sets the job's Remove_Files attribute to *remove options*. Overrides default path names for these streams. Overrides -o and -e options.

This attribute cannot be altered once the job has begun execution.

Default: unset; neither is removed

The *remove options* argument can take the following values:

Table 2-13: discard Argument Values

Option	Meaning
e	The standard error stream is removed (deleted) upon job completion
o	The standard output stream is removed (deleted) upon job completion
eo, oe	Both standard output and standard error streams are removed (deleted) upon job completion
unset	Neither stream is removed

-S <path list>

Specifies the interpreter or shell path for the job script. Sets job's Shell_Path_List attribute to *path list*.

The *path list* argument is the full path to the interpreter or shell including the executable name.

Only one path may be specified without a hostname. Only one path may be specified per named host. The path selected is the one whose hostname is that of the server on which the job resides.

This attribute can be altered after the job has begun execution, but in this case the new value will not take effect until the job is rerun.

Format:

<path>[@<hostname>][,<path>@<hostname> ...]

If the path contains spaces, it must be quoted. For example:

```
qsub -S "C:Program Files\PBS Pro\bin\pbs_python.exe" <script name>
```

Default: user's login shell on execution node

Example of using `bash` via a directive:

```
#PBS -S /bin/bash@mars,/usr/bin/bash@jupiter
```

Example of running a Python script from the command line on Linux:

```
qsub -S $PBS_EXEC/bin/pbs_python <script name>
```

Example of running a Python script from the command line on Windows:

```
qsub -S %PBS_EXEC%\bin\pbs_python.exe <script name>
```

-u <user list>

Alters list of usernames. Job will run under a username from this list. Sets job's User_List attribute to *user list*.

Only one username may be specified without a hostname. Only one username may be specified per named host. The server on which the job resides will select first the username whose hostname is the same as the server name. Failing that, the next selection will be the username with no specified hostname. The usernames on the server and execution hosts must be the same. The job owner must have authorization to run as the specified user.

This attribute cannot be altered once the job has begun execution.

Format: *<username>[@<hostname>][,<username>@<hostname> ...]*

Default: Job owner (username on submit host)

-W <additional attributes>

Each sub-option to the -W option allows you to change a specific job attribute.

Format: *-W <attribute name> = <attribute value>[,<attribute name>=<attribute value>...]*

If white space occurs within the *additional attributes* argument, or the equal sign ("=") occurs within an *attribute value* string, that argument or string must be enclosed in single or double quotes. PBS supports setting the following attributes via the -W option:

depend=<dependency list>

Defines dependencies between this and other jobs. Sets the job's depend attribute to *dependency list*. The *dependency list* has the form:

<type>:<arg list>[,<type>:<arg list> ...]

where except for the *on* type, the *<arg list>* is one or more PBS job IDs in the form:

<job ID>[:<job ID> ...]

The types and their argument lists can be:

after: <arg list>

This job may be scheduled for execution at any point after all jobs in *arg list* have started execution.

afterok: <arg list>

This job may be scheduled for execution only after all jobs in *arg list* have terminated with no errors. See section 2.40.6.1, "Warning About Exit Status with csh", on page 142.

afternotok: <arg list>

This job may be scheduled for execution only after all jobs in *arg list* have terminated with errors. See section 2.40.6.1, "Warning About Exit Status with csh", on page 142.

afterany: <arg list>

This job may be scheduled for execution after all jobs in *arg list* have terminated, with or without errors. This job will not run if a job in the *arg list* was deleted without ever having been run.

before: <arg list>

Jobs in *arg list* may begin execution once this job has begun execution.

beforeok: <arg list>

Jobs in *arg list* may begin execution once this job terminates without errors. See section 2.40.6.1, "Warning About Exit Status with csh", on page 142.

beforenotok: <arg list>

If this job terminates execution with errors, jobs in *arg list* may begin. See section 2.40.6.1, "Warning About Exit Status with csh", on page 142.

beforeany: <arg list>

Jobs in *arg list* may begin execution once this job terminates execution, with or without errors.

on: <count>

This job may be scheduled for execution after *count* dependencies on other jobs have been satisfied. This type is used in conjunction with one of the *before* types listed. *count* is an integer greater than *0*.

runone:<job ID>

Puts the current job and the job with *job ID* in a set of jobs out of which PBS will eventually run just one. To add a job to a set, specify the job ID of another job already in the set.

Restrictions:

Job IDs in the *arg list* of *before* types must have been submitted with a type of *on*.

To use the *before* types, the user must have the authority to alter the jobs in *arg list*. Otherwise, the dependency is rejected and the new job aborted.

Error processing of the existence, state, or condition of the job on which the newly-submitted job depends is performed after the job is queued. If an error is detected, the new job is deleted by the server. Mail is sent to the job submitter stating the error.

Dependency examples:

```
qalter -W depend = afterok:123.host1.domain.com /tmp/script
qalter -W depend= before:234.host1.com:235.host1.com /tmp/script
```

group_list=<group list>

Alters list of group names. Job will run under a group name from this list. Sets job's group_List attribute to *group list*.

Only one group name may be specified without a hostname. Only one group name may be specified per named host. The server on which the job resides will select first the group name whose hostname is the same as the server name. Failing that, the next selection is the group name with no specified hostname. The group names on the server and execution hosts must be the same.

Format: *<group>[@<hostname>][,<group>@<hostname> ...]*

Default: no default

release_nodes_on_stageout=<value>

When set to *True*, all of the job's vnodes not on the primary execution host are released when stageout begins.

When cgroups is enabled and this is used with some but not all vnodes from one MoM, resources on those vnodes that are part of a cgroup are not released until the entire cgroup is released.

The job's stageout attribute must be set for the release_nodes_on_stageout attribute to take effect.

Format: *Boolean*

Default: *False*

run_count=<count>

Sets the number of times the server thinks it has run the job. Sets the job's run_count attribute to *count*. Can be altered while job is running. Job is held when the value of this attribute goes over *20*.

Format: Integer greater than or equal to zero

sandbox=<sandbox spec>

Changes which directory PBS uses for the job's staging and execution. Sets job's sandbox attribute to the value of *sandbox spec*.

Format: *String*

Allowed values for *sandbox spec*:

PRIVATE

PBS creates a job-specific directory for staging and execution.

HOME or unset

PBS uses the user's home directory for staging and execution.

stagein=<path list>

stageout=<path list>

Changes files or directories to be staged in before execution or staged out after execution is complete. Sets the job's stagein and stageout attributes to the specified *path list*s. On completion of the job, all staged-in and staged-out files and directories are removed from the execution host(s). A *path list* has the form:

<filespec>[,<filespec>]

where *filespec* is

<execution path>@<hostname>:<storage path>

regardless of the direction of the copy. The *execution path* is the name of the file or directory on the primary execution host. It can be relative to the staging and execution directory on the execution host, or it can be an absolute path.

The "@" character separates *execution path* from *storage path*.

The *storage path* is the path on *hostname*. The name can be relative to the staging and execution directory on the primary execution host, or it can be an absolute path.

If *path list* has more than one *filespec*, i.e. it contains commas, it must be enclosed in double quotes.

If you use a UNC path, the hostname is optional. If you use a non-UNC path, the hostname is required.

umask=<mask value>

Alters the umask with which the job is started. Controls umask of job's standard output and standard error. Sets job's umask attribute to *mask value*.

Format: one to four digits; typically two

The following example allows group and world read of the job's output and error:

```
-W umask=33
```

Default: *system default*

--version

The `qalter` command returns its PBS version information and exits. This option can only be used alone.

2.40.4 Operands

The `qalter` command accepts a *job ID* list as its operand. The *job ID* list is a space-separated list of one or more job IDs for normal jobs or array jobs.

Subjobs and ranges of subjobs are not alterable.

Job IDs have the form:

<sequence number>[.<server name>][@<server name>]

<sequence number>[][.<server name>][@<server name>]

Note that some shells require that you enclose a job array ID in double quotes.

2.40.5 Standard Error

The `qalter` command writes a diagnostic message to standard error for each error occurrence.

2.40.6 Exit Status

Zero

Upon successful processing of input

Greater than zero

Upon failure

2.40.6.1 Warning About Exit Status with csh

If a job is run in `csh` and a `.logout` file exists in the home directory in which the job executes, the exit status of the job is that of the `.logout` script, not the job script. This may impact any inter-job dependencies.

2.40.7 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide, "Job Attributes" on page 327, Chapter 5, "List of Built-in Resources", on page 259

2.41 qdel

Deletes PBS jobs

2.41.1 Synopsis

qdel [-x] [-Wforce| -Wsuppress_email=<N>] <job ID> [<job ID> ...]

qdel --version

2.41.2 Description

The `qdel` command deletes jobs in the order given, whether they are at the local server or at a remote server.

2.41.2.1 Usage

The `qdel` command is used without options to delete queued, running, held, or suspended jobs, while the `-x` option gives it the additional capacity to delete finished or moved jobs. With the `-x` option, this command can be used on finished and moved jobs, in addition to queued, running, held, or suspended jobs.

When this command is used without the `-x` option, if job history is enabled, the deleted job's history is retained. The -x option is used to additionally remove the history of the job being deleted.

If someone other than the job's owner deletes the job, mail is sent to the job's owner, or to a list of mail recipients if specified during `qsub`. See "qsub" on page 216.

If the job is in the process of provisioning, it can be deleted only by using the `-W force` option.

2.41.2.2 How Behavior of `qdel` Command Can Be Affected

The server's default_qdel_arguments attribute may affect the behavior of the `qdel` command. This attribute is settable by the administrator via the `qmgr` command. The attribute may be set to "*-Wsuppress_email=<N>*". The server attribute is overridden by command-line arguments. See section 6.6, "Server Attributes", on page 281.

2.41.2.3 Sequence of Events

1. The job's running processes are killed.
2. The epilogue runs.
3. Files that were staged in are staged out. This includes standard out (.o) and standard error (.e) files.
4. Files that were staged in or out are deleted.
5. The job's temp directory is removed.
6. The job is removed from the MoM(s) and the server.

2.41.2.4 Required Privilege

A PBS job may be deleted by its owner, an Operator, or the administrator. The MoM deletes a PBS job by sending a SIGTERM signal, then, if there are remaining processes, a SIGKILL signal.

2.41.3 Options to `qdel`

(no options)

Can delete queued, running, held, or suspended jobs. Does not delete job history for specified job(s).

-W force

Deletes the job whether or not the job's execution host is reachable. Deletes the job whether or not the job is in the process of provisioning. Cannot be used with the `-Wsuppress_email` option.

If the server can contact the MoM, this option is ignored; the server allows the job to be deleted normally. If the server cannot contact the MoM or the job is in the *E* state, the server deletes its information about the job.

-Wsuppress_email=<N>

Sets limit on number of emails sent when deleting multiple jobs or subjobs.

- If *N* >= *1* and *N* or more *job IDs* are given, *N* emails are sent.
- If *N* >=*1* and less than *N* job identifiers are given, the number of emails is the same as the number of jobs.
- If *N* = *0*, this option is ignored.
- If *N* = *-1*, no mail is sent.

Note that there is no space between "`W`" and "`suppress_email`".

The *N* argument is an integer.

Cannot be used with `-Wforce` option.

-x

Can delete running, queued, suspended, held, finished, or moved jobs. Deletes job history for the specified job(s).

--version

The `qdel` command returns its PBS version information and exits. This option can only be used alone.

2.41.4 Operands

The `qdel` command accepts one or more space-separated *job ID* operands. These operands can be job identifiers, job array identifiers, subjob identifiers, or subjob range identifiers.

Job IDs have the form:

<sequence number>[.<server name>][@<server name>]

Job arrays have the form:

<sequence number>[][.<server name>][@<server name>]

Subjobs have the form:

<sequence number>[<index>][.<server name>][@<server name>]

Ranges of subjobs have the form:

<sequence number>[<first>-<last>][.<server name>][@<server name>]

Job array identifiers must be enclosed in double quotes for some shells.

2.41.5 Standard Error

The `qdel` command writes a diagnostic message to standard error for each error occurrence.

2.41.6 Exit Status

Zero
: Upon successful processing of input

Greater than zero
: Upon error

2.41.7 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide

2.42 qdisable

Prevents a queue from accepting jobs

2.42.1 Synopsis

qdisable <destination> [<destination> ...]

qdisable --version

2.42.2 Description

The `qdisable` command prevents a queue from accepting batch jobs. Sets the value of the queue's enabled attribute to *False*. If the command is accepted, the queue no longer accepts Queue Job requests. Jobs already in the queue continue to be processed. You can use this to drain a queue of jobs.

2.42.2.1 Required Permission

In order to execute `qdisable`, the user must have PBS Operator or Manager privilege.

2.42.3 Options

--version

The `qdisable` command returns its PBS version information and exits. This option can only be used alone.

2.42.4 Operands

The `qdisable` command accepts one or more space-separated *destination* operands. The operands take any of the following forms:

<queue name>

Prevents specified queue at default server from accepting jobs.

@<server name>

Prevents all queues at specified server from accepting jobs.

<queue name>@<server name>

Prevents specified queue at specified server from accepting jobs.

To prevent all queues at the default server from accepting jobs, use the `qmgr` command:

```
Qmgr: set queue @default enabled=false
```

2.42.5 Standard Error

The `qdisable` command writes a diagnostic message to standard error for each error occurrence.

2.42.6 Exit Status

Zero
: Upon successful processing of all the operands

Greater than zero
: If the `qdisable` command fails to process any operand

2.42.7 See Also

The PBS Professional Administrator's Guide, "qmgr" on page 152, "qenable" on page 148

2.43 qenable

Allows a queue to accept jobs

2.43.1 Synopsis

qenable <destination> [<destination> ...]

qenable --version

2.43.2 Description

The `qenable` command allows a queue to accept batch jobs. Sets the value of the queue's enabled attribute to *True*. If the command is accepted, the *destination* accepts Queue Job requests.

2.43.2.1 Required Privilege

In order to execute `qenable`, the user must have PBS Operator or Manager privilege.

2.43.3 Options

--version

The `qenable` command returns its PBS version information and exits. This option can only be used alone.

2.43.4 Operands

The `qenable` command accepts one or more space-separated *destination* operands. The operands take any of the following forms:

<queue name>

Allows specified queue at default server to accept jobs.

@<server name>

Allows all queues at specified server to accept jobs.

<queue name>@<server name>

Allows specified queue at specified server to accept jobs.

To allow all queues at the default server to accept jobs, use the `qmgr` command:

```
Qmgr: set queue @default enabled=true
```

2.43.5 Standard Error

The `qenable` command writes a diagnostic message to standard error for each error occurrence.

2.43.6 Exit Status

Zero

Upon successful processing of all the operands

Greater than zero

If the `qenable` command fails to process any operand

2.43.7 See Also

The PBS Professional Administrator's Guide, "qmgr" on page 152, "qdisable" on page 146

2.44 qhold

Holds PBS batch jobs

2.44.1 Synopsis

qhold [-h <hold list>] <job ID> [<job ID> ...]

qhold --version

2.44.2 Description

Places one or more holds on a job. A job that has a hold is not eligible for execution. Can be used on jobs and job arrays, but not on subjobs or ranges of subjobs.

If a job identified by *job ID* is in the queued, held, or waiting states, all that occurs is that the hold type is added to the job. The job is then put into the held state if it resides in an execution queue.

If the job is running, the result of the `qhold` command depends upon whether the job can be checkpointed. The job can be checkpointed if the OS supports checkpointing, or if the application being checkpointed supports checkpointing. See the PBS Professional Administrator's Guide. If the job can be checkpointed, the following happens:

- The job is checkpointed and its execution is interrupted.
- The resources assigned to the job are released.
- The job is placed in the held state in the execution queue.
- The job's Hold_Types attribute is set to *u* for *user hold*.

If checkpoint / restart is not supported, `qhold` simply sets the job's Hold_Types attribute to *u*. The job continues to execute.

A job's dependency places a *system* hold on the job. When the dependency is satisfied, the *system* hold is removed. If the administrator sets a *system* hold on a job with a dependency, when the dependency is satisfied, the job becomes eligible for execution.

If the job is in the process of provisioning, it cannot be held.

A hold on a job can be released by the PBS Administrator, root, a Manager, an Operator, or the job owner, when the job reaches the time set in its Execution_Time attribute, or when a dependency clears. See "qrls" on page 183.

2.44.2.1 Effect of Privilege on Behavior

The following table shows the holds and the privilege required to set each:

Table 2-14: Hold Types

Hold Type	Meaning	Who Can Set
u	*User*	*Job owner, Operator, Manager, PBS Administrator, root*
o	*Other*	*Operator, Manager, PBS Administrator, root*
s	*System*	*Manager, PBS Administrator, root, PBS (dependency)*
n	*No hold*	*Job owner, Operator, Manager, PBS Administrator, root*
p	*Bad password*	*PBS Administrator, root*

2.44.3 Options to `qhold`

(no options)

Same as `-h u`. Applies the *user* hold to the specified job(s).

-h <hold list>

Types of holds to be placed on the job(s).

The *hold list* argument is a string consisting of one or more of the letters "*u*", "*o*", or "*s*" in any combination, or one of the letters "*n*" or "*p*".

--version

The `qhold` command returns its PBS version information and exits. This option can only be used alone.

2.44.4 Operands

The `qhold` command can be used on jobs and job arrays, but not on subjobs or ranges of subjobs. The `qhold` command accepts one or more *job IDs* in the form:

<sequence number>[.<server name>][@<server name>]

<sequence number>[][.<server name>][@<server name>]

Note that some shells require that you enclose a job array identifier in double quotes.

2.44.5 Standard Error

The `qhold` command writes a diagnostic message to standard error for each error occurrence.

2.44.6 Exit Status

Zero

Upon successful processing of all operands

Greater than zero

If the `qhold` command fails to process any operand

2.44.7 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide, "qrls" on page 183

2.45 qmgr

Administrator's command interface for managing PBS

2.45.1 Synopsis

At shell command line:

qmgr -c '<directive> [-a] [-e] [-n] [-z]'

qmgr -c 'help [<help option>]'

qmgr <return>

qmgr --version

In qmgr session:

<directive> [-a] [-e] [-n] [-z]

help <help option>

2.45.2 Description

The PBS manager command, `qmgr`, provides a command-line interface to parts of PBS. The `qmgr` command is used to create or delete queues, vnodes, resources, and hooks, to set or change vnode, queue, hook, server, or scheduler attributes and resources, and to view information about hooks, queues, vnodes, resource definitions, the server, and schedulers.

For a list of quick summaries of information about syntax, commands, attributes, operators, names, and values, type "`help`" or "`?`" at the `qmgr` prompt. See section 2.45.11, “Printing Usage Information”, on page 173.

2.45.2.1 Modes of Operation

- When you type `qmgr -c '<directive>'`, `qmgr` performs its task and then exits.
- When you type `qmgr <return>`, `qmgr` starts a session and presents you with its command line prompt. The `qmgr` command then reads directives etc. from standard input; see section 2.45.4.1, “Directive Syntax”, on page 154. You can edit the command line; see section 2.45.2.4, “Reusing and Editing the qmgr Command Line”, on page 153.

  For a `qmgr` prompt, type:

  ```
  qmgr <return>
  ```

  You will see the `qmgr` prompt:

  ```
  Qmgr:
  ```

2.45.2.2 Required Privilege

The `qmgr` command requires different levels of privilege depending on the operation to be performed.

All users can list or print attributes except for hook attributes.

PBS Operator or Manager privilege is required in order to set or change vnode, queue, server, or scheduler attributes. PBS Manager privilege is required in order to create or delete queues, vnodes, and resources.

Under Linux, root privilege is required in order to create hooks, or operate on hooks or the job_sort_formula server attribute. Under Windows, this must be done from the installation account.

For domained environments, the installation account must be a local account that is a member of the local Administrators group on the local computer.

Users without manager or operator privilege cannot view custom resources or resource definitions which were created to be invisible to users.

2.45.2.3 When To Run qmgr At Server Host

Run the qmgr command at the server host when operating on hooks or on the job_sort_formula server attribute.

2.45.2.4 Reusing and Editing the qmgr Command Line

You can reuse or edit qmgr command lines. The qmgr command maintains a history of commands entered, up to a maximum of 500. You can use the 'history' command to see a numbered list of commands, and the !<n> command to execute the line whose number is *n*. You must not put any spaces between the bang ("!") and the number. For example, to execute the 123rd command, type the following:

```
!123
```

You can see the last *m* commands by typing 'history m'. For example, to see the last 6 commands, type the following:

```
history 6
```

You can use the up and down arrows to navigate through the command history list, and the left and right arrows to navigate within a command line. Within a command line, you can use emacs commands to move forward and backward, and delete characters.

You can edit the qmgr command line using the backspace and delete keys, and you can insert characters anywhere in a command line.

History is maintained across qmgr sessions, so that if you start qmgr, then exit, then restart it, you can reuse your commands from the previous session. If you exit qmgr and then restart it, the command lines are renumbered.

If you enter the same command line more than once in a row, only one occurrence is recorded in the history. If you enter the same command line multiple times, but intersperse other command lines after each line, each occurrence is recorded.

Each user's history is unique to that user on that host.

In the case where an account runs concurrent sessions, the most recent logout of a session overwrites history from previous logouts. For example, if two people are both logged in as root and using qmgr, the second person to log out overwrites the history file.

2.45.2.4.i The qmgr History File

The qmgr command stores and retrieves its history. First, it tries to write its history in the ${HOME}/.pbs_qmgr_history file. If this file or directory location is not writable, the command stores its history in $PBS_HOME/spool/.pbs_qmgr_history_<user name>. If this file is also not writable, the following happens:

- The qmgr command prints error messages once at qmgr startup
- The qmgr command cannot provide history across qmgr sessions

2.45.3 Options to qmgr

The following table lists the options to qmgr:

Table 2-15: qmgr Options

Option	Action
<return>	Starts a qmgr session and presents user with qmgr prompt
-a	Aborts qmgr on any syntax errors or any requests rejected by a server.
-c '<directive>'	Executes a single command (*directive*) and exit qmgr. The *directive* must be enclosed in single or double quote marks, for example: qmgr -c "print server"
-c 'help [<help option>]'	Prints out usage information. See "Printing Usage Information" on page 173
-e	Echoes all commands to standard output
-n	No commands are executed; syntax checking only is performed
-z	No errors are written to standard error
--version	The qmgr command returns its PBS version information and exits. This option can only be used alone

2.45.4 Directives

A qmgr *directive* is a *command* together with the *object(s)* to be operated on, the *attribute(s)* belonging to the object that is to be changed, the *operator*, and the *value(s)* the *attribute(s)* will take. In the case of resources, you can set the *type* and/or *flag*(s).

2.45.4.1 Directive Syntax

A directive is terminated by a newline or a semicolon (";"). Multiple directives may be entered on a single line. A directive may extend across lines by escaping the newline with a backslash ("\").

Comments begin with the "#" character and continue to the end of the line. Comments and blank lines are ignored by qmgr.

2.45.4.1.i Server, Scheduler, Queue, Vnode Directives

Syntax for operating on servers, schedulers, queues, and vnodes:

<command> <object type> [<object name(s)>] [<attribute> <operator> <value>[,<attribute> <operator> <value>,...]]

For information about attributes, see Chapter 6, "Attributes", on page 277.

2.45.4.1.ii Resource Directives

Syntax for operating on resources:

<command> <resource name> [<resource name> ...] [type = <type>][,flag = <flag(s)>]

For information about resources, see "Using PBS Resources" on page 227 in the PBS Professional Administrator's Guide and Chapter 5, "List of Built-in Resources", on page 259.

2.45.4.1.iii Hook-only Directives

The directives here apply only to hooks. Other directives apply to all objects such as queues, resources, hooks, etc.

Syntax for importing and exporting site-defined hooks:

"*import hook <hook name> application/x-python <content-encoding> (<input file> | -)*"

"*export hook <hook name> <content-type> <content-encoding>*" > *[<output file>]*

Syntax for importing site-defined hook configuration file:

"*import hook <hook name> application/x-config <content-encoding> (<input file> | -)*"

Syntax for importing built-in hook configuration file:

"*import pbshook <hook name> application/x-config <content-encoding> (<input file> | -)*"

2.45.4.2 Using Directives

You can use a *directive* from the shell command line or from within the `qmgr` session.

- To use a directive from the command line, enclose the command and its arguments in single or double quotes.

  qmgr -c '<command> <command arguments>'

  For example, to have `qmgr` print server information and exit:

  ```
  qmgr -c "print server"
  ```

- To use a directive from within the `qmgr` session, first start `qmgr`:

  ```
  qmgr <return>
  ```

  The `qmgr` session presents a `qmgr` prompt:

  ```
  Qmgr:
  ```

  At the `qmgr` prompt, enter the directive (a command and its arguments). For example, to enter the same "print server" directive:

  ```
  Qmgr: print server
  ```

2.45.4.3 Commands Used in Directives

Commands can be abbreviated to their minimum unambiguous form. Commands apply to all target objects unless explicitly limited. The following table lists the commands, briefly tells what they do, and gives a link to a full description:

Table 2-16: `qmgr` Commands Used in Directives

Command	Abbr.	Effect	Description
`active`	`a`	Specifies active objects	See section 2.45.6.1, “Making Objects Active”, on page 159
`create`	`c`	Creates object	See section 2.45.6.2, “Creating Objects (Server, Scheduler, Vnode, Queue, Hook)”, on page 160
`delete`	`d`	Deletes object	See section 2.45.6.3, “Deleting Objects”, on page 160
`exit`		Exits (quits) the `qmgr` session	
`export`	`e`	Exports hook or hook configuration file	See section 2.45.10.6, “Exporting Hooks”, on page 172 and section 2.45.10.5.ii, “Exporting Configuration Files”, on page 171

Table 2-16: `qmgr` Commands Used in Directives

Command	Abbr.	Effect	Description
`help or ?`	`h, ?`	Prints usage to `stdout`	See section 2.45.11, "Printing Usage Information", on page 173
`import`	`i`	Imports hook or configuration file	See section 2.45.10.4, "Importing Hooks", on page 170 or section 2.45.10.5.i, "Importing Configuration Files", on page 171
`list`	`l`	Lists object attributes and their values	See section 2.45.8.1, "Listing Objects and Their Attributes", on page 167
`print`	`p`	Prints creation and configuration commands	See section 2.45.8.3, "Printing Creation and Configuration Commands", on page 169
`quit`	`q`	Quits (exits) the `qmgr` session	
`set`	`s`	Sets value of attribute	See section 2.45.7.1, "Setting Attribute and Resource Values", on page 161
`unset`	`u`	Unsets value of attribute	See section 2.45.7.2, "Unsetting Attribute and Resource Values", on page 162

2.45.5 Arguments to Directive Commands

2.45.5.1 Object Arguments to Directive Commands

The `qmgr` command can operate on objects (servers, schedulers, queues, vnodes, resources, hooks, and built-in hooks). Each of these can be abbreviated inside a directive. The following table lists the objects and their abbreviations:

Table 2-17: `qmgr` Objects

Object Name	Abbr.	Object	Can Be Created/Deleted By:	Can Be Modified By:
server	*s*	server	No one (created at installation)	Administrator, Operator, Manager
sched	*sc*	default scheduler	No one (created at installation)	Administrator, Operator, Manager
		multisched	Administrator, Manager	Administrator, Operator, Manager
queue	*q*	queue	Administrator, Operator, Manager	Administrator, Operator, Manager
node	*n*	vnode	Administrator, Operator, Manager	Administrator, Operator, Manager
resource	*r*	resource	Administrator, Manager	Administrator, Manager
hook	*h*	hook	Linux: root Windows: installation account	Linux: root Windows: installation account
pbshook	*p*	built-in hook	No one (created at installation)	Linux: root Windows: installation account

2.45.5.1.i Specifying Active Server

The qmgr command operates on objects (queues, vnodes, etc.) at the active server. There is always at least one active server; the default server is the active server unless other servers have been made active. The default server is the server managing the host where the qmgr command runs, meaning it is the server specified in that host's pbs.conf file. Server names have the following format:

<hostname>[:<port number>]

where *hostname* is the fully-qualified domain name of the host on which the server is running and *port number* is the port number to which to connect. If *port number* is not specified, the default port number, *15001*, is used.

- To specify the default server:

  @default
- To specify a named server:

  @<server name>
- To specify all active servers:

  @active

2.45.5.1.ii Using Lists of Object Names

In a qmgr directive, *object name(s)* is a list of one or more names of specific objects. The administrator specifies the name of an object when creating the object. The name list is in the form:

<object name>[@<server>][,<object name>[@<server>] ...]

where *server* is replaced in the directive with "*default*", "*active*", or the name of the server. The name list must conform to the following:

- There must be no space between the object name and the @ sign.
- Name lists must not contain white space between entries.
- All objects in a list must be of the same type.
- Node attributes cannot be used as vnode names.

2.45.5.1.iii Specifying Object Type and Name

You can specify objects in the following ways:

- To act on the active objects of the named type, at the active server:

  <object type>

  For example, to list all active vnodes, along with their attributes, at the active server:

  ```
  Qmgr: list node
  ```
- To act on the active objects of the named type, at a specified server:

  <object type> @<server name> (note space before @ sign)

  For example, to list all active vnodes at the default server, along with their attributes:

  ```
  Qmgr: list node @default
  ```

  For example, to print out all queues at the default server, along with their attributes:

  ```
  qmgr -c "print queue @default"
  ```
- To act on a specific named object:

  <object type> <object name>

  For example, to list Node1 and its attributes:

  ```
  Qmgr: list node Node1
  ```

To list queues workq, slowq, and fastq at the active server:

```
Qmgr: list queue workq,slowq,fastq
```

- To act on the named object at the specified server:

  <object type> <object name>@<server name>

  For example, to list Node1 at the default server, along with the attributes of Node1:

  ```
  Qmgr: list node Node1@default
  ```

  To list queues Queue1 at the default server, Queue2 at Server2, and Queue3 at the active server:

  ```
  Qmgr: list queue Queue1@default,Queue2@Server2,Queue3@active
  ```

2.45.5.2 Operators in Directive Commands

In a `qmgr` directive, *operator* is the operation to be performed with the attribute and its value. Operators are listed here:

Table 2-18: Operators in Directive Commands

Operator	Effect
=	Sets the value of the attribute or resource. If the attribute or resource has an existing value, the current value is replaced with the new value.
+=	Increases the current value of the attribute or resource by the amount in the new value. When used for a string array, adds the new value as another string after a comma.
-=	Decreases the current value of the attribute or resource by the specified amount. When used for a string array, removes the first matching string.

Example 2-4: Set routing destination for queue Queue1 to be Dest1:

```
Qmgr: set queue route_destinations = Dest1
```

Example 2-5: Add new routing destination for queue Queue1:

```
Qmgr: set queue route_destinations += Dest2
```

Example 2-6: Remove new routing destination for queue Queue1:

```
Qmgr: set queue route_destinations -= Dest2
```

When setting numerical resource values, you can use only the equal sign ("=").

2.45.5.3 Windows Requirements For Directive Arguments

Under Windows, use double quotes when specifying arguments to `qmgr`. For example:

```
Qmgr: import hook hook1 application/x-python default "\Documents and
   Settings\pbsuser1\hook1.py"
```

or

```
qmgr -c 'import hook hook1 application/x-python default "\Documents and Set-
   tings\pbsuser1\hook1.py"'
```

2.45.6 Operating on Objects (Server, Scheduler, Vnode, Queue, Hook)

2.45.6.1 Making Objects Active

Making objects active is a way to set up a list of objects, all of the same type, on which you can then use a single command. For example, if you are going to set the same attribute to the same value on several vnodes, you can make all of the target vnodes active before using a single command to set the attribute value, instead of having to give the command once for each vnode. You can make any type of object active except for resources or hooks.

When an object is active, it is acted upon when you specify its type but do not specify names. When you specify any object names in a directive, active objects are not operated on unless they are named in the directive.

You can specify a list of active objects for each type of object. You can have active objects of multiple types at the same time. The active objects of one type have no effect on whether objects of another type are active.

Objects are active only until the `qmgr` command is exited, so this feature can be used only at the `qmgr` prompt.

Each time you make any objects active at a given server, that list of objects replaces any active objects of the same kind at that server. For example, if you have four queues at a particular server, and you make Q1 and Q2 active, then later make Q3 and Q4 active, the result is that Q3 and Q4 are the only active queues.

You can make different objects be active at different servers simultaneously. For example, you can set vnodes N1 and N2 at the default server, and vnodes N3 and N4 at server Server2 to be active at the same time.

To make all objects inactive, quit `qmgr`. When you quit `qmgr`, any object that was active is no longer active.

2.45.6.1.i Using the `active` Command

- To make the named object(s) of the specified type active:

  active <object type> [<object name>[,<object name> ...]]

  Example: To make queue Queue1 active:

  ```
  Qmgr: active queue Queue1
  ```

  Example: To make queues Queue1 and Queue2 at the active server be active, then enable them:

  ```
  Qmgr: active queue Queue1,Queue2
  Qmgr: set queue enabled=True
  ```

  Example: To make queue Queue1 at the default server and queue Queue2 at Server2 be active:

  ```
  Qmgr: active queue Queue1@default,Queue2@Server2
  ```

  Example: To make vnodes N1, N2, N3, and N4 active, and then give them all the same value for their max_running attribute:

  ```
  Qmgr: active node N1,N2,N3,N4
  Qmgr: set node max_running = 2
  ```

- To make all object(s) of the specified type at the specified server active:

  active <object type> @<server name> (note space before @ sign)

  Example: To make all queues at the default server active:

  ```
  Qmgr: active queue @default
  ```

  Example: To make all vnodes at server Server2 active:

  ```
  Qmgr: active node @Server2
  ```

- To report which objects of the specified type are active:

  active <object type>

  The `qmgr` command prints a list of names of active objects of the specified type to `stdout`.

2.45.6.2 Creating Objects (Server, Scheduler, Vnode, Queue, Hook)

- To create one new object of the specified type for each name, and give it the specified name:

  create <object type> <object name>[,<object name> ...] [[<attribute> = <value>] [,<attribute> = <value>] ...]

  Can be used only with multischeds, queues, vnodes, resources, and hooks. Cannot be used with built-in hooks.

  For example, to create a multisched named multisched_1 at the active server:

  Qmgr: create sched multisched_1

  For example, to create a queue named Q1 at the active server:

  Qmgr: create queue Q1

  For example, to create a vnode named N1 and a vnode named N2:

  Qmgr: create node N1,N2

  For example, to create queue Queue1 at the default server and queue Queue2 at Server2:

  Qmgr: create queue Queue1@default,Queue2@Server2

  For example, to create vnodes named N1, N2, N3, and N4 at the active server, and to set their Mom attribute to *Host1* and their max_running attribute to *1*:

  Qmgr: create node N1,N2,N3,N4 Mom=Host1, max_running = 1

  To create a host-level consumable string resource named "foo" that can be read and set by execution hooks:

  Qmgr: qmgr -c "create resource foo type=string,flag=mnh"

All objects of the same type at a server must have unique names. For example, each queue at server Server1 must have a unique name. Objects at one server can have the same name as objects at another server.

You can create multiple objects of the same type with a single command. You cannot create multiple types of objects in a single command.

To create multiple resources of the same type and flag, separate each resource name with a comma:

qmgr -c "create resource <resource>[,<resource> ...] type=<type>,flag=<flag(s)>"

2.45.6.2.i Examples of Creating Objects

Example 2-7: Create queue:

```
create queue fast priority=10,queue_type=e,enabled = true,max_running=0
```

Example 2-8: Create queue, set resources:

```
create queue little
set queue little resources_max.mem=8mw,resources_max.cput=10
```

2.45.6.3 Deleting Objects

- To delete the named object(s):

  delete <object type> <object name>[,<object name> ...]

  When you delete more than one object, do not put a space after a comma.

  Can be used only with queues, vnodes, resources, and hooks. Cannot be used with built-in hooks.

  For example, to delete queue Q1 at the active server:

  Qmgr: delete queue Q1

  For example, to delete vnodes N1 and N2 at the active server:

  Qmgr: delete node N1,N2

For example, to delete queue Queue1 at the default server and queue Queue2 at Server2:

```
Qmgr: delete queue Queue1@default,Queue2@Server2
```

For example, to delete resource "foo" at the active server:

```
Qmgr: delete resource foo
```

- To delete the active objects of the specified type:

  delete <object type>

  For example, to delete the active queues:

  ```
  Qmgr: delete queue
  ```

- To delete the active objects of the specified type at the specified server:

  delete <object type> @<server name>

  For example, to delete the active queues at server Server2:

  ```
  Qmgr: delete queue @Server2
  ```

You can delete multiple objects of the same type with a single command. You cannot delete multiple types of objects in a single command. To delete multiple resources, separate the resource names with commas.

For example:

```
Qmgr: delete resource r1,r2
```

You cannot delete a resource that is requested by a job or reservation, or that is set on a server, queue, or vnode.

2.45.7 Operating on Attributes and Resources

You can specify attributes and resources for named objects or for all objects of a type.

2.45.7.1 Setting Attribute and Resource Values

- To set the value of the specified attribute(s) for the named object(s):

  set <object type> <object name>[,<object name> ...] <attribute> = <value> [,<attribute> = <value> ...]

  Each specified attribute is set for each named object, so if you specify three attributes and two objects, both objects get all three attributes set.

- To set the attribute value for all active objects when there are active objects of the type specified:

  set <object type> <attribute> = <value>

- To set the attribute value for all active objects at the specified server when there are active objects of the type specified:

  set <object type> @<server name> <attribute> = <value>

  For example, to set the amount of memory on a vnode:

  ```
  Qmgr: set node Vnode1 resources_available.mem = 2mb
  ```

If the attribute is one which describes a set of resources such as resources_available, resources_default, resources_max, resources_used, etc., the attribute is specified in the form:

<attribute name>.<resource name>

You can have spaces between *attribute=value* pairs.

2.45.7.1.i Examples of Setting Attribute Values

Example 2-9: Increase limit on queue:

```
set queue fast max_running +=2
```

Example 2-10: Set software resource on mynode:

```
set node mynode resources_available.software = "myapp=/tmp/foo"
```

Example 2-11: Set limit on queue:

```
set queue Queue1 max_running = 10
```

Example 2-12: Set vnode offline:

```
set node Node1 state = "offline"
```

2.45.7.2 Unsetting Attribute and Resource Values

You can use the qmgr command to unset attributes of any object, except for the type attribute of a built-in hook.

- To unset the value of the specified attributes of the named object(s):
  unset <object type> <object name>[,<object name> ...] <attribute>[,<attribute>...]
- To unset the value of specified attributes of active objects:
  unset <object type> <attribute>[,<attribute>...]
- To unset the value of specified attributes of the named object:
  unset <object type> <object name> <attribute>[,<attribute>...]
- To unset the value of specified attributes of the named object:
  unset <object type> @<server name> <attribute>[,<attribute>...]

2.45.7.2.i Example of Unsetting Attribute Value

Example 2-13: Unset limit on queue

```
unset queue fast max_running
```

2.45.7.3 Caveats and Restrictions for Setting Attribute and Resource Values

- If the value includes whitespace, commas or other special characters, such as the # character, the value string must be enclosed in single or double quotes. For example:
  ```
  Qmgr: set node Vnode1 comment="Node will be taken offline Friday at 1:00 for memory
     upgrade."
  ```
- You can set or unset attribute values for only one type of object in each command.
- You can use the qmgr command to set attributes of any object, except for the type attribute of a built-in hook.
- You can have spaces between attribute names.
- Attribute and resource values must conform to the format for the attribute or resource type. Each attribute's type is listed in Chapter 6, "Attributes", on page 277. Each format is described in Chapter 7, "Formats", on page 353.
- Most of a vnode's attributes may be set using qmgr. However, some **must** be set on the individual execution host in Version 2 vnode configuration files, NOT by using qmgr. See "Configuring Vnodes" on page 45 in the PBS Professional Administrator's Guide.

2.45.7.4 Setting Custom Resource Type

You can use the qmgr command to set or unset the type for custom resources.

Resource types can be the following; see section 7.2, “Resource Formats”, on page 359:

string

boolean

string_array

long

size

float

- To set a custom resource type:

  set resource <resource name> type = <type>

  Sets the type of the named resource to the specified *type*. For example:

  ```
  Qmgr: qmgr -c "set resource foo type=string_array"
  ```

2.45.7.5 Setting Custom Resource Level and Consumability

When you define a custom resource, you specify whether it is server-level or host-level, and whether it is consumable or not by setting resource accumulation flags via `qmgr`. A consumable resource is tracked, or accumulated, in the server, queue or vnode resources_assigned attribute. The resource accumulation flags determine where the value of resources_assigned.<resource name> is incremented.

2.45.7.5.i Allowable Values for Resource Accumulation Flags

The value of *<resource flags>*, which is the resource accumulation flag for a resource can be one of the following:

Table 2-19: Resource Accumulation Flags

Flag	Meaning
(no flags)	Indicates a queue-level or server-level resource that is not consumable.
fh	The amount is consumable at the host level for only the first vnode allocated to the job (vnode with first task.) Must be consumable or time-based. Cannot be used with Boolean or string resources. . This flag specifies that the resource is accumulated at the first vnode, meaning that the value of resources_assigned.<resource> is incremented only at the first vnode when a job is allocated this resource or when a reservation requesting this resource on this vnode starts.

Table 2-19: Resource Accumulation Flags

Flag	Meaning
h	Indicates a host-level resource. Used alone, means that the resource is not consumable. Required for any resource that will be used inside a select statement. This flag selects hardware. This flag indicates that the resource must be requested inside of a select statement. Example: for a Boolean resource named "green": `Qmgr: create resource green type=boolean, flag=h`
nh	The amount is consumable at the host level, for all vnodes assigned to the job. Must be consumable or time-based. Cannot be used with Boolean or string resources. This flag specifies that the resource is accumulated at the vnode level, meaning that the value of resources_assigned.<resource> is incremented at relevant vnodes when a job is allocated this resource or when a reservation requesting this resource on this vnode starts. This flag is not used with dynamic consumable resources. The scheduler will not oversubscribe dynamic consumable resources.
q	The amount is consumable at the queue and server level. When a job is assigned one unit of a resource with this flag, the resources_assigned.<resource> attribute at the server and any queue is incremented by one. Must be consumable or time-based. This flag specifies that the resource is accumulated at the queue and server level, meaning that the value of resources_assigned.<resource> is incremented at each queue and at the server when a job is allocated this resource. When a reservation starts, allocated resources are added to the server's resources_assigned attribute. This flag is not used with dynamic consumable resources. The scheduler will not oversubscribe dynamic consumable resources.

2.45.7.5.ii When to Use Accumulation Flags

The following table shows when to use accumulation flags.

Table 2-20: When to Use Accumulation Flags

Resource Category	Server	Queue	Host
Static, consumable	flag = q	flag = q	flag = nh or fh
Static, not consumable	flag = (none of h, n, q or f)	flag = (none of h, n, q or f)	flag = h
Dynamic	`server_dyn_res` line in `sched_config`, flag = (none of h, n, q or f)	(cannot be used)	Tracked using an exechost_periodic hook flag = h

2.45.7.5.iii Example of Resource Accumulation Flags

When defining a static consumable host-level resource, such as a node-locked application license, you would use the "n" and "h" flags.

When defining a dynamic resource such as a floating license, you would use no flags.

2.45.7.5.iv Resource Accumulation Flag Restrictions and Caveats

Numeric dynamic resources cannot have the q or n flags set. This would cause these resources to be under-used. These resources are tracked automatically by the scheduler.

2.45.7.6 Setting Custom Resource Visibility

When you define a custom resource, you can specify whether unprivileged users have permission to view or request the resource, and whether users can `qalter` a request for that resource. This is done by setting a resource permission flag via `qmgr`.

2.45.7.6.i Allowable Values for Resource Permission Flags

The permission flag for a resource can be one of the following:

Table 2-21: Resource Permission Flags

Flag	Meaning
(no flag)	Users can view and request the resource, and `qalter` a resource request for this resource.
i	"Invisible". Users cannot view or request the resource. Users cannot `qalter` a resource request for this resource.
r	"Read only". Users can view the resource, but cannot request it or `qalter` a resource request for this resource.

2.45.7.6.ii Effect of Resource Permission Flags

- PBS Operators and Managers can view and request a resource, and `qalter` a resource request for that resource, regardless of the i and r flags.
- Users, operators and managers cannot submit a job which requests a restricted resource. Any job requesting a restricted resource will be rejected. If a manager needs to run a job which has a restricted resource with a different value from the default value, the manager must submit the job without requesting the resource, then `qalter` the resource value.
- While users cannot request these resources, their jobs can inherit default resources from resources_default.<resource name> and default_chunk.<resource name>.

  If a user tries to request a resource or modify a resource request which has a resource permission flag, they will get an error message from the command and the request will be rejected. For example, if they try to `qalter` a job's resource request, they will see an error message similar to the following:

  ```
  "qalter: Cannot set attribute, read only or insufficient permission  Resource_List.hps 173.mars"
  ```

2.45.7.6.iii Resource Permission Flag Restrictions and Caveats

- You can specify only one of the i or r flags per resource. If both are specified, the resource is treated as if only the i flag were specified, and an error message is logged at the default log level and printed to standard error.
- Resources assigned from the default_qsub_arguments server attribute are treated as if the user requested them. A job will be rejected if it requests a resource that has a resource permission flag whether that resource was requested by the user or came from default_qsub_arguments.
- The behavior of several command-line interfaces is dependent on resource permission flags. These interfaces are those which view or request resources or modify resource requests:

`pbsnodes`

Users cannot view restricted host-level custom resources.

`pbs_rstat`

Users cannot view restricted reservation resources.

`pbs_rsub`

Users cannot request restricted custom resources for reservations.

`qalter`

Users cannot alter a restricted resource.

`qmgr`

Users cannot print or list a restricted resource.

`qselect`

Users cannot specify restricted resources via -l Resource_List.

`qsub`

Users cannot request a restricted resource.

`qstat`

Users cannot view a restricted resource.

2.45.7.7 Specifying Whether Custom Resource is Cached at MoM

You can make it faster for execution hooks to read custom job resources. Execution hooks cannot read custom job resources via the event, only via the server. However, you can cache a copy of a custom job resource at the MoMs for faster local reading by execution hooks, by setting the *m* flag for the resource. The job resources that can be cached are found in the following job attributes:

exec_vnode
Resource_List
resources_used

To create a resource with the *m* flag set, include the flag. For example, to create two host-level consumable resources r1 and r2 of type long that will be cached at MoMs:

```
qmgr -c "create resource r1,r2 type=long,flag=mnh"
```

To unset this flag for r1:

```
qmgr -c "set resource r1 flag=nh"
```

You can combine this flag with any other resource flag. Job resources created in an exechost_startup hook have the m flag set automatically.

2.45.7.7.i Caveats for Caching Custom Job Resources

Large numbers of job resources that are cached at MoMs can slow things down. If you don't need execution hooks to be able to read a custom job resource often, don't cache the resource at the MoMs.

2.45.7.7.ii Examples of Defining Custom Resources and Setting Flags via qmgr

To set the type for a resource:

set resource <resource name> type = <type>

For example:

```
qmgr -c "set resource foo type=string_array"
```

To set the flags for a resource:

set resource <resource name> flag=<flag(s)>

For example:

```
qmgr -c "set resource foo flag=nh"
```

To set the type and flags for a resource:

set resource <resource name> type=<type>, flag=<flag(s)>

For example:

```
qmgr -c "set resource foo type=long,flag=nhi"
```

You can set multiple resources by separating the names with commas. For example:

```
qmgr -c "set resource r1, r2 type=long"
```

You cannot set the *nh*, *fh*, or *q* flag for a resource of type string, string_array, or Boolean.

You cannot set both the *n* and the *f* flags on one resource.

You cannot have the *n* or *f* flags without the *h* flag.

You cannot set both the *i* and *r* flags on one resource.

You cannot unset the type for a resource.

You cannot set the type for a resource that is requested by a current or history job or reservation, or set on a server, queue, or vnode.

You cannot set the flag(s) to *h*, *nh*, *fh*, or *q* for a resource that is currently requested by a current or history job or reservation.

You cannot unset the flag(s) for a resource that is currently requested by a current or history job or a reservation, or set on any server, queue, or vnode.

You cannot alter a built-in resource.

You can unset custom resource flags, but not their type.

2.45.8 Viewing Object, Attribute, and Resource Information

2.45.8.1 Listing Objects and Their Attributes

You can use the `qmgr` command to list attributes of any object, including attributes at their default values.

- To list the attributes, with associated values, of the named object(s):

  list <object type> <object name>[,<object name> ...]
- To list values of the specified attributes of the named object:

  list <object type> <object name> <attribute name>[, <attribute name>]...
- To list attributes, with associated values, of active objects of the specified type at the active server:

  list <object type>
- To list all objects of the specified type at the specified server, with their attributes and the values associated with the attributes:

  list <object type> @<server name>
- To list attributes of the active server:

list server

If no server other than the default server has been made active, lists attributes of the default server (it is the active server).

- To list attributes of the specified server:

  list server <server name>
- To list attributes of all schedulers:

  list sched
- To list attributes of the specified scheduler:

  list sched <scheduler name>
- To list all hooks, along with their attributes:

  list hook
- To list attributes of the specified hook:

  list hook <hook name>

2.45.8.1.i Examples of Listing Objects and Their Attributes

Example 2-14: List serverA's schedulers' attributes:

```
list sched @serverA
```

Example 2-15: List attributes for default server's scheduler(s):

```
l sched @default
```

Example 2-16: List PBS version for default server's scheduler(s):

```
l sched @default pbs_version
```

Example 2-17: List queues at a specified server:

```
list queue @server1
```

2.45.8.2 Listing Resource Definitions

You can use the `qmgr list` and `print` commands to list resource definitions showing resource name, type, and flag(s).

- To list the name, type, and flag(s) of the named resource(s):

  list resource <resource name>[,<resource name> ...]

  or

  print resource <resource name>[,<resource name> ...]
- To list name, type, and flag(s) of custom resources only:

  list resource

  or

  print resource

  or

  print server (note that this also prints information for the active server)
- To list all custom resources at the specified server, with their names, types, and flags:

  list resource @<server name>

  or

  print resource @<server name>

When used by a non-privileged user, qmgr prints only resource definitions for resources that are visible to non-privileged users (those that do not have the *i* flag set).

2.45.8.3 Printing Creation and Configuration Commands

For printing the creation commands for any object except for a built-in hook.

- To print out the commands to create the named object(s) and set their attributes to their current values:

  print <object type> <object name>[,<object name> ...]

  where *object name* follows the name rules in section 2.45.5.1.ii, “Using Lists of Object Names”, on page 157.
- To print out the commands to create the named object and set its attributes to their current values:

  print <object type> <object name> [<attribute name>[, <attribute name>]...]

  where *object name* follows the name rules in section 2.45.5.1.ii, “Using Lists of Object Names”, on page 157.
- To print out the commands to create and configure the active objects of the named type:

  print <object type>
- To print out the commands to create and configure all of the objects of the specified type at the specified server:

  print <object type> @<server name>
- To print out the commands to create each queue, set the attributes of each queue to their current values, and set the attributes of the server to their current values:

  print server

  This is used for the server and queues, but not hooks.

  Prints information for the active server. If there is no active server, prints information for the default server.
- To print out the creation commands for all schedulers:

  print sched
- To print out the creation commands for the specified scheduler:

  print sched <scheduler name>

2.45.8.4 Caveats for Viewing Information

Some attributes whose values are unset do not appear in the output of the qmgr command.

Definitions for built-in resources do not appear in the output of the qmgr command.

When a non-privileged user prints resource definitions, qmgr prints only resource definitions for resources that are visible to non-privileged users (those that do not have the *i* flag set).

2.45.9 Saving and Re-creating Server and Queue Information

To save and recreate server and queue configuration, print the configuration information to a file, then read it back in later. For example, to save your configuration:

```
# qmgr -c "print server" > savedsettings
```

or

```
Qmgr: print server > savedsettings
```

When re-creating queue and server configuration, read the commands back into qmgr. For example:

```
qmgr < savedsettings
```

2.45.10 Operating on Hooks

2.45.10.1 Creating Hooks

- To create a hook:

  Qmgr: create hook <hook name>

  For example:

  Qmgr: create hook my_hook

2.45.10.2 Deleting Hooks

- To delete a hook:

  Qmgr: delete hook <hook name>

  For example:

  Qmgr: delete hook my_hook

2.45.10.3 Setting and Unsetting Hook Attributes

- To set a hook attribute:

  Qmgr: set hook <hook name> <attribute> = <value>
- To unset a hook attribute:

  Qmgr: unset hook <hook name> <attribute>

Example 2-18: Unset hook1's alarm attribute, causing hook1's alarm to revert to its default value of 30 seconds:

Qmgr: unset hook hook1 alarm

2.45.10.4 Importing Hooks

For importing the contents of a site-defined hook. Cannot be used with built-in hooks.

To import a hook, you import the contents of a hook script into the hook. You must specify a filename that is locally accessible to `qmgr` and the PBS server.

Format for importing a site-defined hook:

import hook <hook name> application/x-python <content encoding> {<input file> | -}

This uses the contents of *input file* or `stdin` (-) as the contents of hook *hook name*.

- The *input file* or `stdin` (-) data must have a format of *content type* and must be encoded with *content encoding*.
- The allowed values for *content encoding* are "*default*" (7bit) and "*base64*".
- If the source of input is `stdin` (-) and *content encoding* is "*default*", `qmgr` expects the input data to be terminated by *EOF*.
- If the source of input is `stdin` (-) and *content encoding* is "base64", `qmgr` expects input data to be terminated by a blank line.
- *input file* must be locally accessible to both `qmgr` and the requested batch server.
- A relative path *input file* is relative to the directory where `qmgr` was executed.
- If a hook already has a content script, that is overwritten by this import call.
- If the name in *input file* contains spaces as are used in Windows filenames, *input file* must be quoted.

There is no restriction on the size of the hook script.

2.45.10.4.i Examples of Importing Hooks

Example 2-19: Given a Python script in ASCII text file "hello.py", use its contents as the script contents of hook1:

```
#cat hello.py
import pbs
pbs.event().job.comment="Hello, world"
# qmgr -c 'import hook hook1 application/x-python default hello.py'
```

Example 2-20: Given a base64-encoded file "hello.py.b64", qmgr unencodes the file's contents, and then makes this the script contents of hook1:

```
# cat hello.py.b64
cHJpbnQgImhlbGxvLCB3b3JsZCIK
# qmgr -c 'import hook hook1 application/x-python base64 hello.py.b64'
```

Example 2-21: To create a provisioning hook called Provision_Hook, and import the ASCII hook script called "master_provision.py" located in /root/data/:

```
Qmgr: create hook Provision_Hook
Qmgr: import hook Provision_Hook application/x-python default
   /root/data/master_provision.py
```

2.45.10.5 Importing and Exporting Hook Configuration Files

2.45.10.5.i Importing Configuration Files

For importing the contents of a site-defined or built-in hook configuration file. To import a hook configuration file, you import the contents of a file to a hook. You must specify a filename that is locally accessible to qmgr and the PBS server.

Format for importing a site-defined hook configuration file:

import hook <hook name> application/x-config <content encoding> {<config file>|-}

Format for importing a built-in hook configuration file:

import pbshook <hook name> application/x-config <content encoding> {<config file>|-}

This uses the contents of *config file* or stdin (-) as the contents of the configuration file for hook *hook name*.

- The *config file* or stdin (-) data must have a format of *content-type* and must be encoded with *content encoding*.
- The allowed values for *content encoding* are "*default*" (7bit) and "*base64*".
- If the source of input is stdin (-) and *content encoding* is "*default*", qmgr expects the input data to be terminated by *EOF*.
- If the source of input is stdin (-) and *content encoding* is "base64", qmgr expects input data to be terminated by a blank line.
- *config file* must be locally accessible to both qmgr and the requested batch server.
- A relative path *config file* is relative to the directory where qmgr was executed.
- If a hook already has a configuration file, that file is overwritten by this import call.
- If the name in *config file* contains spaces as are used in Windows filenames, *input file* must be quoted.

There is no restriction on the size of the hook configuration file.

2.45.10.5.ii Exporting Configuration Files

Format for exporting a site-defined hook configuration file:

qmgr -c "export hook <hook name> application/x-config default" > {<config file>|-}

Format for exporting a built-in hook configuration file:

qmgr -c "export pbshook <hook name> application/x-config default" > {<config file>|-}

2.45.10.5.iii Hook Configuration File Format

PBS supports several file formats for configuration files. The format of the file is specified in its suffix. Formats can be any of the following:

- .ini
- .json
- .py (Python)
- .txt (generic, no special format)
- .xml
- No suffix: treat the input file as if it is a .txt file
- The dash (-) symbol: configuration file content is taken from STDIN. The content is treated as if it is a .txt file.

Example 2-22: To import a configuration file in .json format:

```
# qmgr -c "import hook my_hook application/x-config default my_input_file.json"
```

2.45.10.6 Exporting Hooks

For exporting the contents of a site-defined hook. Cannot be used with built-in hooks.

Format for exporting a hook:

qmgr -c "export hook <hook name> <content type> <content encoding>" > [<output file>]

This dumps the script contents of hook *hook name* into *output file*, or stdout if *output file* is not specified.

- The resulting *output file* or stdout data is of *content type* and *content encoding*.
- The only *content type* currently supported is "*application/x-python*".
- The allowed values for *content encoding* are "*default*" (7bit) and "*base64*".
- *output file* must be a path that can be created by qmgr.
- Any relative path *output file* is relative to the directory where qmgr was executed.
- If *output file* already exists it is overwritten. If PBS is unable to overwrite the file due to ownership or permission problems, an error message is displayed in stderr.
- If the *output file* name contains spaces like the ones used in Windows file names, *output file* must be enclosed in quotes.

2.45.10.6.i Examples of Exporting Hooks

Example 2-23: Dump hook1's script contents directly into a file "hello.py.out":

```
# qmgr -c "export hook hook1 application/x-python default" > hello.py
# cat hello.py
import pbs
pbs.event().job.comment="Hello, world"
```

Example 2-24: To< dump the script contents of a hook 'hook1' into a file in "\My Hooks\hook1.py":

```
qmgr -c "export hook hook1 application/x-python default" > "\My Hooks\hook1.py"
```

2.45.10.7 Printing Hook Information

- To print out the commands to create and configure all hooks, including their configuration files:

print hook

- To print out the commands to create and configure the specified hook, including its configuration file:

  print hook <hook name>

2.45.10.8 Saving and Re-creating Hook Information

You can save creation and configuration information for all hooks. For example:

```
# qmgr -c "print hook" > hook.qmgr
```

You can re-create all hooks and their configuration files. For example:

```
# qmgr < hook.qmgr
```

2.45.10.9 Restrictions on Built-in Hooks

You cannot do the following with built-in hooks:

- Import a built-in hook
- Export a built-in hook
- Print creation commands for a built-in hook
- Create a built-in hook
- Delete a built-in hook
- Set the type attribute for a built-in hook

2.45.11 Printing Usage Information

You use the `help` command or a question mark ("?") to invoke the `qmgr` built-in help function. You can request usage information for any of the `qmgr` commands, and for topics including attributes, operators, names, and values.

- To print out usage information for the specified command or topic:

  Qmgr: help [<command or topic>]

  or

  Qmgr: ? [<command or topic>]

  For example, to print usage information for the `set` command:

```
qmgr
Qmgr: help set
Syntax: set object [name][,name...] attribute[.resource] OP value
```

2.45.12 Standard Input

When you start a `qmgr` session, the `qmgr` command reads standard input for directives until it reaches end-of-file, or it reads the *exit* or *quit* command.

2.45.13 Standard Output

When you start a `qmgr` session, and standard output is connected to a terminal, `qmgr` writes a command prompt to standard output.

If you specify the `-e` option, `qmgr` echoes the directives it reads from standard input to standard output.

2.45.14 Standard Error

If you do not specify the `-z` option, the `qmgr` command writes a diagnostic message to standard error for each error occurrence.

2.45.15 Exit Status

0
: Success

1
: Error in parsing

2
: Error in execution

3
: Error connecting to server

4
: Error making object active

5
: Memory allocation error

2.45.16 See Also

The PBS Professional Administrator's Guide, Chapter 6, "Attributes", on page 277, Chapter 5, "List of Built-in Resources", on page 259

2.46 qmove

Moves a PBS job from one queue to another

2.46.1 Synopsis

qmove <destination> <job ID> [<job ID> ...]

qmove --version

2.46.2 Description

Moves a job from one queue to another.

The behavior of the qmove command may be affected by any site hooks. Site hooks can modify the job's attributes, change its routing, etc.

2.46.2.1 Restrictions

The qmove command can be used on job arrays, but not on subjobs or ranges of subjobs.

Job arrays can only be moved from one server to another if they are in the '*Q*', '*H*', or '*W*' states, and only if there are no running subjobs. The state of the job array is preserved, and the job array will run to completion on the new server.

A job in the *Running*, *Transiting*, or *Exiting* state cannot be moved.

A job in the process of provisioning cannot be moved.

2.46.2.2 Effect of Privilege on Behavior

An unprivileged user can use the qmove command to move a job only when the move would not violate queue restrictions. A privileged user (root, Manager, Operator) can use the qmove command to move a job under some circumstances where an unprivileged user cannot. The following restrictions apply only to unprivileged users:

- The queue must be enabled
- Moving the job into the queue must not exceed the queue's limits for jobs or resources
- If the job is an array job, the size of the job array must not exceed the queue's max_array_size
- The queue cannot have its from_route_only attribute set to *True* (accepting jobs only from routing queues)

2.46.3 Options

--version

The qmove command returns its PBS version information and exits. This option can only be used alone.

2.46.4 Operands

destination

Where job(s) are to end up. First operand. Syntax:

<queue name>

Moves the job(s) into the specified queue at the job's current server.

@<server name>

Moves the job(s) into the default queue at specified server.

<queue name>@<server name>

Moves the job(s) into the specified queue at the specified server.

See Chapter 7, "Formats", on page 353 for destination identifier formats.

job ID

Job(s) and/or job array(s) to be moved to the new destination . The `qmove` command accepts one or more *job ID* operands of the form:

<sequence number>[.<server name>][@<server name>]

<sequence number>[][.<server name>][@<server name>]

Note that some shells require that you enclose a job array identifier in double quotes.

2.46.5 Standard Error

The `qmove` command writes a diagnostic messages to standard error for each error occurrence.

2.46.6 Exit Status

Zero

Upon successful processing of all the operands presented to the `qmove` command.

Greater than zero

If the `qmove` command fails to process any operand.

2.46.7 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide

2.47 qmsg

Writes message string into one or more job output files

2.47.1 Synopsis

qmsg [-E] [-O] <message string> <job ID> [<job ID> ...]

qmsg --version

2.47.2 Description

Writes a message string into one or more output files of the job. Typically this is done to leave an informative message in the output of the job. Also called "sending a message to a job".

The `qmsg` command writes messages into the files of jobs by sending a Message Job batch request to the batch server that owns the job. The `qmsg` command does not directly write the message into the files of the job.

The `qmsg` command can be used on jobs and subjobs, but not on job arrays or ranges of subjobs.

2.47.3 Options

-E
: The message is written to the standard error of each job.

-O
: The message is written to the standard output of each job.

--version
: The `qmsg` command returns its PBS version information and exits. This option can only be used alone.

(no options)
: The message is written to the standard error of each job.

2.47.4 Operands

message string
: The message to be written. String. First operand. If the string contains blanks, the string must be quoted. If the final character of the string is not a newline, a newline character is added when written to the job's file.

job ID
: The job(s) to receive the message string. This operand follows the *message string* operand. Can be a job or subjob. Cannot be a job array or range of subjobs. The `qmsg` command accepts one or more *job ID* operands.

  Format for job:

  <sequence number>[.<server name>][@<server name>]

  Format for subjob. Note that a subjob has square brackets around its index number:

  <sequence number>[<index>][.<server name>][@<server name>]

2.47.5 Standard Error

The `qmsg` command writes a diagnostic message to standard error for each error occurrence.

2.47.6 Exit Status

Zero

Upon successful processing of all the operands presented to the `qmsg` command.

Greater than zero

If the `qmsg` command fails to process any operand.

2.47.7 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide

2.48 qorder

Swaps queue positions of two PBS jobs

2.48.1 Synopsis

qorder <job ID> <job ID>

qorder --version

2.48.2 Description

Exchanges positions in queue(s) of two jobs, whether in the same or different queue(s).

No attribute of either job, e.g. priority, is changed. The impact of interchanging the order within or between queues is dependent on local job scheduling policy; contact your systems administrator.

2.48.2.1 Restrictions

- A job in the running state cannot be reordered.
- The `qorder` command can be used on job arrays, but not on subjobs or ranges of subjobs.
- The two jobs must be located at the same server.

2.48.2.2 Effect of Privilege on Behavior

For an unprivileged user to reorder jobs, both jobs must be owned by the user. A privileged user (Manager, Operator) can reorder any jobs.

2.48.3 Options

--version

The `qorder` command returns its PBS version information and exits. This option can only be used alone.

2.48.4 Operands

Both operands are job IDs which specify the jobs to be exchanged. The `qorder` command accepts two *job ID* operands of the form:

<sequence number>[.<server name>][@<server name>]

<sequence number>[][.<server name>][@<server name>]

If you specify the server for both jobs, they must be at the same server.

Note that some shells require that you enclose a job array identifier in double quotes.

2.48.5 Standard Error

The `qorder` command writes diagnostic messages to standard error for each error occurrence.

2.48.6 Exit Status

Zero
: Upon successful processing of all the operands presented to the `qorder` command

Greater than zero
: If the `qorder` command fails to process any operand

2.48.7 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide

2.49 qrerun

Requeues a PBS job

2.49.1 Synopsis

qrerun [-W force] <job ID> [<job ID> ...]

qrerun --version

2.49.2 Description

If possible, kills the specified job(s), then requeues each job in the execution queue from which it was run.

The `qrerun` command can be used on jobs, job arrays, subjobs, and ranges of subjobs. If you give a job array identifier as an argument, the job array is returned to its initial state at submission time, or to its altered state if it has been qaltered. All of that job array's subjobs are requeued, which includes those that are currently running, and those that are completed and deleted. If a you give a subjob or range as an argument, those subjobs are requeued.

2.49.2.1 Restrictions

If a job is marked as not rerunnable, `qrerun` neither kills nor requeues the job. See the `-r` option for the `qsub` and `qalter` commands, and the Rerunable job attribute.

The `qrerun` command cannot requeue a job or subjob which is not running, is held, or is suspended.

2.49.2.2 Required Privilege

PBS Manager or Operator privilege is required to use this command.

2.49.3 Options

-W force
: The job is to be requeued even if the vnode on which the job is executing is unreachable, or if the job's substate is *provisioning*.

--version
: The `qrerun` command returns its PBS version information and exits. This option can only be used alone.

2.49.4 Operands

The `qrerun` command accepts one or more *job ID* operands of the form:

<sequence number>[.<server name>][@<server name>]

<sequence number>[][.<server name>][@<server name>]

<sequence number>[<index>][.<server name>][@<server name>]

<sequence number>[<index start>-<index end>][.<server name>][@<server name>]

Note that some shells require that you enclose a job array identifier in double quotes.

2.49.5 Standard Error

The `qrerun` command writes a diagnostic message to standard error for each error occurrence.

2.49.6 Exit Status

Zero
: Upon successful processing of all operands

Greater than zero
: Upon failure to process any operand

2.50 qrls

Releases holds on PBS jobs

2.50.1 Synopsis

qrls [-h <hold list>] <job ID> [<job ID> ...]

qrls --version

2.50.2 Description

The `qrls` command directly releases or removes holds on batch jobs or job arrays, and indirectly on subjobs with a System hold. You cannot use the command with a specified range of subjobs. If you use `qrls` on a job array which has a System hold because it has one or more subjobs with a System hold, the System hold is removed from the subjobs, then from the job array.

A job may have one or more types of holds which make the job ineligible for execution.

When you `qrls` a job whose Execution_Time attribute is not set to a time in the future, the job changes to the *queued* state. If Execution_Time is in the future, the job changes to the *waiting* state.

Holds can be set by the owner, an Operator, or Manager, when a job has a dependency, or when a job has its Execution_Time attribute set to a time in the future. See "qhold" on page 150.

2.50.2.1 Effect of Privilege on Behavior

The following table shows the holds and the privilege required to release each:

Table 2-22: Hold Types

Hold Type	Meaning	Privilege Required to Release
u	*User*	*Job owner, Operator, Manager, PBS Administrator, root*
o	*Other*	*Operator, Manager, administrator, root*
s	*System*	*Manager, administrator, root, PBS (dependency)*
n	*No hold*	*Job owner, Operator, Manager, administrator, root*
p	*Bad password*	*Administrator, root*

If you try to release a hold for which the you do not have privilege, the entire request is rejected, and no holds are released.

2.50.3 Options

(no options)

Defaults to `-h u`, removing *user* hold.

-h <hold list>

Types of hold to be released for the jobs. The *hold list* option argument is a string consisting of one or more of the letters *u, o,* or *s* in any combination, or one of the letters *n* or *p*.

--version

The `qrls` command returns its PBS version information and exits. This option can only be used alone.

2.50.4 Operands

The `qrls` command can be used directly on jobs and job arrays, but indirectly on subjobs, and cannot be used on ranges of subjobs. The `qrls` command accepts one or more *job ID* operands of the form:

<sequence number>[.<server name>][@<server name>]

<sequence number>[][.<server name>][@<server name>]

Note that some shells require that you enclose a job array identifier in double quotes.

2.50.5 Standard Error

The `qrls` command writes a diagnostic message to standard error for each error occurrence.

2.50.6 Exit Status

Zero

Upon successful processing of all the operands presented to the `qrls` command

Greater than zero

If the `qrls` command fails to process any operand

2.50.7 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide, "qhold" on page 150

2.51 qrun

Runs a PBS job immediately

2.51.1 Synopsis

qrun [-a] [-H <vnode specification>] <job ID> [<job ID> ...]

qrun [-a] [-H -] <job ID> [<job ID> ...]

qrun --version

2.51.2 Description

Forces a job to run, regardless of scheduling position or resource requirements.

The `qrun` command can be used on jobs, subjobs, or ranges of subjobs, but not on job arrays. When it is used on a range of subjobs, the non-running subjobs in that range are run.

When preemption is enabled, a scheduler preempts other jobs in order to run this job. Running a job via `qrun` gives the job higher preemption priority than any of the priorities defined in the preempt_prio scheduler parameter. See "Using Preemption" on page 179 in the PBS Professional Administrator's Guide.

2.51.2.1 Required Privilege

In order to execute `qrun`, you must have PBS Operator or Manager privilege.

2.51.2.2 Caveats for qrun

- The job is run without respect for limits, primetime, or dedicated time.
- If you use a `-H <vnode specification>` option to run a job, but specify insufficient vnodes or resources, the job may not run correctly. Avoid using this option unless you are sure.
- If you don't use the -H option, the job must be in the *Queued* state and reside in an execution queue.
- If you do use the -H option, the job must be in the *Queued* or *Suspended* state and reside in an execution queue.
- The `qrun` command cannot be used on a job that is in the process of provisioning.
- If you use the `-H` option, all schedulers are bypassed, and partition boundaries are ignored.
- If you use `qrun` on a subjob, PBS will try to run the subjob regardless of whether the job has hit the limit specified in max_run_subjobs.

2.51.3 Options to `qrun`

-a

The `qrun` command exits before the job actually starts execution.

(no -H option)

The job is run immediately regardless of scheduling policy as long as the following are true:

- The queue in which the job resides is an execution queue.
- Either the resources required by the job are available, or preemption is enabled and the required resources can be made available by preempting jobs that are running.

The `qrun` command by itself, with no `-H` option, overrides the following:

- Limits on resource usage by users, groups, and projects
- Limits on the number of jobs that can be run at a vnode
- Boundaries between primetime and non-primetime, specified in backfill_prime
- Whether the job is in a primetime queue: you can run a job in a primetime slot even when it's not prime-time, or vice versa. Primetime boundaries are not honored.
- Dedicated time: you can run a job in a dedicated time slot, even if it's not in a dedicated time queue, and vice versa. However, dedicated time boundaries are still honored.

The `qrun` command by itself, with no `-H` option, does not override the following:

- Server and queue resource usage limits

(with -H option)

Do **NOT** use this option unless you know exactly what you are doing.

With the `-H` option, all scheduling policies are bypassed and the job is run directly. The job is run immediately on the named or previously-assigned vnodes, regardless of current usage on those vnodes or which scheduler manages those vnodes, with the exception of vnode state. The job is not run and the `qrun` request is rejected if any named vnode is down, already allocated exclusively, or would need to be allocated exclusively and another job is already running on the vnode. The job is run if the vnode is *offline*.

The `-H` option runs jobs that are queued or suspended.

If the `qrun -H` command is used on a job that requests an AOE, and that AOE is not instantiated on those vnodes, the vnodes are provisioned with the AOE.

If the job requests an AOE, and that AOE is not available on the specified vnodes, the job is held.

-H <vnode specification without resources>

The *vnode specification without resources* has this format:

(<vchunk>)[+(<vchunk>) ...]

where *vchunk* has the format

<vnode name>[+<vnode name> ...]

Example:

```
-H (VnodeA+VnodeB)+(VnodeC)
```

PBS applies one requested chunk from the job's selection directive in round-robin fashion to each *vchunk* in the list. Each *vchunk* must be sufficient to run the job's corresponding chunk, otherwise the job may not execute correctly.

-H <vnode specification with resources>

The *vnode specification with resources* has this format:

(<vchunk>)[+(<vchunk>) ...]

where *vchunk* has the format

<vnode name>:<vnode resources>[+<vnode name>:<vnode resources> ...]

and where *vnode resources* has the format

<resource name>=<value>[:<resource name>=<value> ...]

Example:

```
-H (VnodeA:mem=100kb:ncpus=1) +(VnodeB:mem=100kb:ncpus=2+VnodeC:mem=100kb)
```

PBS creates a new selection directive from the *vnode specification with resources*, using it instead of the original specification from the user. Any single resource specification results in the job's original selection directive being ignored. Each *vchunk* must be sufficient to run the job's corresponding chunk, otherwise the job may not execute correctly.

If the job being run requests `-l place=exclhost`, take extra care to satisfy the `exclhost` request. Make sure that if any vnodes are from a multi-vnoded host, all vnodes from that host are allocated. Otherwise those vnodes can be allocated to other jobs.

-H -

Runs the job on the set of resources to which it is already assigned. You can run a job on the set of resources already assigned to the job, without having to list the resources, by using the **-** (dash) argument to the `-H` option.

--version

The `qrun` command returns its PBS version information and exits. This option can only be used alone.

2.51.4 Operands

Job ID

The `qrun` command accepts a list of job IDs, of the form:

<sequence number>[.<server name>][@<server name>]

<sequence number>[<index>][.<server name>][@<server name>]

<sequence number>[<index start>-<index end>][.<server name>][@<server name>]

Note that some shells require that you enclose a job array identifier in double quotes.

vnode specification

The *vnode specification without resources* has this format:

(<vchunk>)[+(<vchunk>) ...]

where vchunk has the format

<vnode name>[+<vnode name> ...]

Example:

```
-H (VnodeA+VnodeB)+(VnodeC)
```

The *vnode specification with resources* has this format:

(<vchunk>)[+(<vchunk>) ...]

where *vchunk* has the format

<vnode name>:<vnode resources>[+<vnode name>:<vnode resources> ...]

and where *vnode resources* has the format

<resource name>=<value>[:<resource name>=<value> ...]

Example:

```
-H (VnodeA:mem=100kb:ncpus=1) +(VnodeB:mem=100kb:ncpus=2+VnodeC:mem=100kb)
```

A *vnode name* is the name of the vnode, not the name of the host.

2.51.5 Standard Error

The `qrun` command writes a diagnostic message to standard error for each error occurrence.

2.51.6 Exit Status

Zero

On success

Greater than zero

If the `qrun` command fails to process any operand

2.51.7 See Also

The PBS Professional Administrator's Guide

2.52 qselect

Selects specified PBS jobs

2.52.1 Synopsis

qselect [-a [<op>] <date and time>] [-A <account string>] [-c [<op>] <interval>] [-h <hold list>] [-H] [-J] [-l <resource list>] [-N <name>] [-p [<op>] <priority>] [-P <project>] [-q <destination>] [-r <rerun>] [-s <states>] [-t <time option> [<comparison>] <specified time>] [-T] [-u <user list>] [-x]

qselect --version

2.52.2 Description

The `qselect` command lists those jobs that meet the specified selection criteria. You can compare certain job attribute values to specified values using a comparison operator shown as *op* in the option description.

You can select jobs, job arrays, or subjobs. You can select jobs from one server per call to the command.

Each option acts as a filter restricting which jobs are listed.

You can select jobs according to the values of some of the resources in the Resource_List job attribute. You can also select jobs according the selection directive (although because this is a string, you can only check for equality or inequality.)

Jobs that are finished or moved are listed only when the `-x` or `-H` options are used. Otherwise, job selection is limited to queued and running jobs.

2.52.2.1 Comparison Operations

You can select jobs by comparing the values of certain job attributes to values you specify. The following table lists the comparison operations you can use:

Table 2-23: Comparison Operations

Operation	Type of Comparison
.eq.	The value of the job attribute is equal to the value of the option argument.
.ne.	The value of the job attribute is not equal to the value of the option argument.
.ge.	The value of the job attribute is greater than or equal to the value of the option argument.
.gt.	The value of the job attribute is greater than the value of the option argument.
.le.	The value of the job attribute is less than or equal to the value of the option argument.
.lt.	The value of the job attribute is less than the value of the option argument.

For example, to select jobs whose Priority attribute has a value greater than 5:

```
qselect -p.gt.5
```

Where an optional comparison is not specified, the comparison operation defaults to *.eq*, meaning PBS checks whether the value of the attribute is equal to the option argument.

2.52.2.2 Required Permissions

When selecting jobs according to resource values, users without operator or manager privilege cannot specify custom resources which were created to be invisible to unprivileged users.

2.52.3 Options to `qselect`

(no options)

Lists all jobs at the server which the user is authorized to list (query status of).

-a [<op>] <date and time>

Deprecated. Restricts selection to those jobs whose Execution_Time attribute qualifies when compared to the *date and time* argument. You can select a range of execution times by using this option twice, to compare to a minimum time and a maximum time.

The *date and time* argument has the format:

[[CC]YY]MMDDhhmm[.SS]

where *MM* is the two digits for the month, *DD* is the day of the month, *hh* is the hour, *mm* is the minute, and the optional *SS* is the seconds. *CC* is the century and *YY* the year.

-A <account string>

Restricts selection to jobs whose Account_Name attribute matches the specified *account string* .

-c [<op>] <interval>

Restricts selection to jobs whose Checkpoint interval attribute meets the comparison criteria.

The *interval* argument can take one of the following values:

c

c=<minutes>

n

s

w

w=<minutes>

We give the range of interval values for the Checkpoint attribute the following ordered relationship:

n > s > c=<minutes> > c > u

(Information about w and w=<minutes> is not available.)

For an interval value of "*u*", only "*.eq.*" and "*.ne.*" are valid.

-h <hold list>

Restricts the selection of jobs to those with a specific set of hold types. The holds in the Hold_Types job attribute must be the same as those in the *hold list* argument, but can be in a different order.

The *hold list* argument is a string consisting of the single letter *n*, or one or more of the letters *u, o, p*, or *s* in any combination. If letters are duplicated, they are treated as if they occurred once. The letters represent the hold types:

Table 2-24: Hold Types

Letter	Hold Type
n	None
u	User
o	Other
p	Bad password
s	System

-H

Restricts selection to finished and moved jobs.

-J

Limits selection to job arrays only.

-l <resource list>

Restricts selection of jobs to those with specified resource amounts. Resource must be job-wide, or be mem, ncpus, or vmem.

The *resource list* is in the following format:

<resource name> <op> <value>[,<resource name> <op> <value> ...]

You must specify *op*, and you can use any of the comparison operators.

Because resource specifications for chunks using the select statement, and placement using the place statement, are stored as strings, the only useful operators for these are *.eq.* and *.ne.*

Unprivileged users cannot specify custom resources which were created to be invisible to unprivileged users.

-N <name>

Restricts selection of jobs to those with the specified value for the Job_Name attribute.

-p [<op>]<priority>

Restricts selection of jobs to those with the specified Priority value(s).

-P <project>

Restricts selection of jobs to those matching the specified value for the project attribute.

Format: *Project Name*; see "Project Name" on page 357

-q <destination>

Restricts selection to those jobs at the specified *destination*.

The *destination* may take of one of the following forms:

<queue name>

Restricts selection to the specified queue at the default server.

@<server name>

Restricts selection to the specified server.

<queue name>@<server name>

Restricts selection to the specified queue at the specified server.

If the -q option is not specified, jobs are selected from the default server.

-r <rerun>

Restricts selection of jobs to those with the specified value for the Rerunable attribute . The option argument *rerun* must be a single character, either *y* or *n* .

-s <states>

Restricts job selection to those whose job_state attribute has the specified value(s).

The *states* argument is a character string consisting of any combination of these characters: *B, E, F, H, M, Q, R, S, T, U, W*, and *X*. (A repeated character is accepted, but no additional meaning is assigned to it.)

Table 2-25: Job States

State	Meaning
B	Job array has started execution
E	The *Exiting* state
F	The *Finished* state
H	The *Held* state
M	The *Moved* state
Q	The *Queued* state
R	The *Running* state
S	The *Suspended* state
T	The *Transiting* state
U	Job suspended due to workstation user activity
W	The *Waiting* state
X	The *eXited* state. Subjobs only

Jobs in any of the specified states are selected.

Job arrays are never in states *R, S, T*, or *U*. Subjobs may be in those states.

-t <time option> [<op>] <specified time>

Jobs are selected according to one of their time-based attributes. The *time option* specifies which time-based attribute is tested. You give the *specified time* in *datetime* format. See Chapter 7, "Formats", on page 353.

The *time option* is one of the following:

Table 2-26: Sub-options to the `-t` Option

Time Option	Time Attribute	Option Format(s)	Attribute Description
a	Execution_Time	*Timestamp* Use *datetime* format to specify.	Time at which the job is eligible for execution.
c	ctime	*Timestamp* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.	Time at which the job was created.
e	etime	*Timestamp* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.	Time when job became eligible to run, i.e. was enqueued in an execution queue and was in the "*Q*" state. Reset when a job moves queues, or is held then released. Not affected by qaltering.
g	eligible_time	Use *duration* format to specify.	Amount of eligible time job accrued waiting to run.
m	mtime	*Timestamp* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.	Time that the job was last modified, changed state, or changed locations.
q	qtime	*Timestamp* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.	Time that the job entered the current queue.
s	stime	*Timestamp* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch	Time the job started. Updated when job is restarted. .
t	estimated.start_time	Use *datetime* format to specify. Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.	Job's estimated start time.

To bracket a time period, use the `-t` option twice. For example, to select jobs using stime between noon and 3 p.m.:

```
qselect -ts.gt.09251200 -ts.lt.09251500
```

-T

Limits selection to jobs and subjobs.

-u <user list>

Restricts selection to jobs owned by the specified usernames.

Syntax of *user list*:

<username>[@<hostname>][,<username>[@<hostname>],...]

Selects jobs which are owned by the listed users at the corresponding hosts. Hostnames may be wildcarded on the left end, e.g. "*.nasa.gov". A username without a "@<hostname>" is equivalent to "<username>@*", meaning that it is valid at any host.

-x

Selects finished and moved jobs in addition to queued and running jobs.

--version

The `qselect` command returns its PBS version information and exits. This option can only be used alone.

2.52.4 Standard Output

PBS writes a list of the selected job IDs to standard output. Each job ID is separated by white space. A job ID can represent a job, a job array, or a subjob. Each job ID has one of the forms:

<sequence number>.<server name>[@<server name>]

<sequence number>[].<server name>[@<server name>]

<sequence number>[<index>].<server name>[@<server name>]

@<server name> identifies the server which currently owns the job.

2.52.5 Standard Error

The `qselect` command writes a diagnostic message to standard error for each error occurrence.

2.52.6 Exit Status

Zero

Upon successful processing of all options presented to the `qselect` command

Greater than zero

If the `qselect` command fails to process any option

2.52.7 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide, section 6.11, “Job Attributes”, on page 327, Chapter 5, "List of Built-in Resources", on page 259

2.53 qsig

Send signal to PBS job

2.53.1 Synopsis

qsig [-s <signal>] <job ID> [<job ID> ...]

qsig --version

2.53.2 Description

The `qsig` command sends a signal to all the processes of the specified job(s). The `qsig` command sends a Signal Job batch request to the server which owns the job.

The `qsig` command can be used for jobs, job arrays, subjobs, and ranges of subjobs. If it is used on a range of subjobs, the running subjobs in the range are signaled.

Not all signal names are recognized by `qsig`; if using a signal name does not work, try issuing the signal number instead.

2.53.2.1 Using admin-suspend and admin-resume

If you have a vnode requiring maintenance while remaining powered up, where you don't want jobs running during the maintenance, you can use the special signals *admin-suspend* and *admin-resume* to suspend and resume the jobs on the vnode. When you use *admin-suspend* on a vnode's job(s), the vnode goes into the *maintenance* state, and its scheduler does not schedule jobs on it. You must separately *admin-suspend* each job on the vnode. When its last *admin-suspend*ed job is *admin-resume*d, a vnode leaves the *maintenance* state.

2.53.2.2 Restrictions

The request to signal a job is rejected if:

- The user is not authorized to signal the job
- The job is not in the *running* or *suspended* state
- The requested signal is not supported by the system upon which the job is executing
- The job is in the process of provisioning
- You attempt to use *admin-resume* on a job that was *suspend*ed
- You attempt to use *resume* on a job that was *admin-suspend*ed

2.53.2.3 Required Privilege

Manager or Operator privilege is required to use the *admin-suspend*, *admin-resume*, *suspend*, or *resume* signals. Unprivileged users can use other signals.

2.53.3 Options to qsig

(no options)

PBS sends SIGTERM to the job.

-s <signal>

PBS sends signal *signal* to the job.

--version

The `qsig` command returns its PBS version information and exits. This option can only be used alone.

2.53.3.1 Signals

You can send standard signals to a job, or the special signals described below. The *signal* argument can be in any of the following formats:

- A signal name, e.g. *SIGKILL*
- A signal name without the SIG prefix, e.g. *KILL*
- An unsigned signal number, e.g. *9*

The signal name *SIGNULL* is allowed; in this case the server sends the signal 0 to the job, which has no effect.

2.53.3.1.i Special Signals

The following special signals are all lower-case, and have no associated signal number:

admin-suspend

Suspends a job and puts its vnodes into the *maintenance* state. The job is put into the *S* state and its processes are suspended. When suspended, a job is not executing and is not charged for walltime.

Syntax: *qsig -s admin-suspend <job ID>*

admin-resume

Resumes a job that was suspended using the *admin-suspend* signal, without waiting for its scheduler. Cannot be used on jobs that were suspended with the *suspend* signal. When the last *admin-suspend*ed job has been *admin-resume*d, the vnode leaves the maintenance state.

Syntax: *qsig -s admin-resume <job ID>*

suspend

Suspends specified job(s). Job goes into *suspended (S)* state. When suspended, a job is not executing and is not charged for walltime.

resume

Marks specified job(s) for resumption by its scheduler when there are sufficient resources. If you use `qsig -s resume` on a job that was suspended using `qsig -s suspend`, the job is resumed when there are sufficient resources. Cannot be used on jobs that were suspended with the *admin_suspend* signal.

2.53.4 Operands

The `qsig` command accepts one or more *job ID* operands. For a job, this has the form:

<sequence number>[.<server name>][@<server name>]

For a job array, *job ID* takes this form:

<sequence number>[][.<server name>][@<server name>]

Note that some shells require that you enclose a job array identifier in double quotes.

2.53.5 Standard Error

The `qsig` command writes a diagnostic message to standard error for each error occurrence.

2.53.6 Exit Status

Zero
: Upon successful processing of all the operands presented to the `qsig` command

Greater than zero
: If the `qsig` command fails to process any operand

2.53.7 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide

2.54 qstart

Turns on scheduling or routing for the jobs in a PBS queue

2.54.1 Synopsis

qstart <destination> [<destination> ...]

qstart --version

2.54.2 Description

If *destination* is an execution queue, the `qstart` command allows a PBS scheduler to schedule jobs residing in the specified queue. If *destination* is a routing queue, the server can begin routing jobs from that queue. Sets the value of the queue's started attribute to *True*.

2.54.2.1 Required Privilege

In order to execute `qstart`, you must have PBS Operator or Manager privilege.

2.54.3 Options

--version

The `qstart` command returns its PBS version information and exits. This option can only be used alone.

2.54.4 Operands

The `qstart` command accepts one or more space-separated *destination* operands. The operands take one of three forms:

<queue name>

Starts scheduling or routing from the specified queue.

@<server name>

Starts scheduling or routing from all queues at the specified server.

<queue name>@<server name>

Starts scheduling or routing from the specified queue at the specified server.

To start scheduling at all queues at the default server, use the `qmgr` command:

```
Qmgr: set queue @default started=true
```

2.54.5 Standard Error

The `qstart` command writes a diagnostic message to standard error for each error occurrence.

2.54.6 Exit Status

Zero
: Upon successful processing of all the operands presented to the `qstart` command

Greater than zero
: If the `qstart` command fails to process any operand

2.54.7 See Also

The PBS Professional Administrator's Guide, "qmgr" on page 152, "qstop" on page 214

2.55 qstat

Displays status of PBS jobs, queues, or servers

2.55.1 Synopsis

2.55.1.1 Displaying Job Status

Default format:

qstat [-E] [-J] [-p] [-t] [-w] [-x] [[<job ID> | <destination>] ...]

Long format:

qstat -f [-F json|dsv [-D <delimiter>]] [-E] [-J] [-p] [-t] [-w] [-x] [[<job ID list> | <destination>] ...]

Alternate format:

qstat [-a | -H | -i | -r] [-E] [-G | -M] [-J] [-n [-1]] [-s [-1]] [-t] [-T] [-u <user list>] [-w] [[<job ID> | <destination>] ...]

2.55.1.2 Displaying Queue Status

Default format:

qstat -Q [<destination> ...]

Long format:

qstat -Q -f [-F json|dsv [-D <delimiter>]] [-w] [<destination> ...]

Alternate format:

qstat -q [-G | -M] [<destination> ...]

2.55.1.3 Displaying Server Status

Default format:

qstat -B [<server name> ...]

Long format:

qstat -B -f [-F json|dsv [-D <delimiter>]] [-w] [<server name> ...]

2.55.1.4 Displaying Version Information

qstat --version

2.55.2 Description

The `qstat` command displays the status of jobs, queues, or servers, writing the status information to standard output.

When displaying job status information, the `qstat` command displays status information about all specified jobs, job arrays, and subjobs. You can specify jobs by ID, or by destination, for example all jobs at a specified queue or server.

2.55.2.1 Display Formats

You can use particular options to display status information in a default format, an alternate format, or a long format. Default and alternate formats display all status information for a job, queue, or server with one line per object, in columns. Long formats display status information showing all attributes, one attribute to a line.

2.55.2.2 Displaying Information for Finished and Moved Jobs

You can display status information for finished and moved jobs by using the -x and -H options.

If your job has been moved to another server through peer scheduling, give the job ID as an argument to `qstat`. If you do not specify the job ID, your job will not appear to exist. For example, your job 123.ServerA is moved to ServerB. In this case, you can use:

```
qstat 123
```

or

```
qstat 123.ServerA
```

Specifying the full job name, including the server, avoids the possibility that `qstat` will report on a job named 123.ServerB that was moved to ServerA.

To list all jobs at ServerB, you can use:

```
qstat @ServerB
```

2.55.2.3 Displaying Truncated Data

When the number of characters required would exceed the space available, `qstat` truncates the output and puts an asterisk ("*") in the last position. For example, in default job display format, there are three characters allowed for the number of cores. If the actual output were *1234*, the value displayed would be *12** instead.

2.55.2.4 Required Privilege

Users without Manager or Operator privilege cannot view resources or attributes that are invisible to unprivileged users.

2.55.3 Displaying Job Status

2.55.3.1 Job Status in Default Format

Triggers: no options, or any of the -J, -p, -t, or -x options.

The `qstat` command displays job status in default format when you specify no options, or any of the -J, -p, -t, or -x options. Jobs are displayed one to a line, with these column headers:

```
Job id   Name       User      Time Use S Queue
-------- ---------- --------- -------- - -----
```

Description of columns:

Table 2-27: Description of Default Job Status Columns

Column	Width without -w	Width with -w	Description	
Job ID	17 (22 when max_job_sequence_id > 10 million	30	Job ID assigned by PBS	
Name	16	15	Job name specified by submitter	
User	16	15	Username of job owner	
Time Use or Percent Complete	8	8	The CPU time used by the job. Before the application has actually started running, for example during stage-in, this field is "0". At the point where the application starts accumulating cput, this field changes to "00:00:00". After that, every time the MoM polls for resource usage, the field is updated. The MoM on each execution host polls for the usage of all processes on her host belonging to the job. Usage is summed. The polling interval is short when a job first starts running and lengthens to a maximum of 2 minutes. See "Configuring MoM Polling Cycle" on page 38 in the PBS Professional Administrator's Guide. If you specify -p, the *Time Use* column is replaced with the percentage completed for the job. For a job array this is the percentage of subjobs completed. For a normal job, it is the percentage of allocated CPU time used.	
S	1	1	The job's state. See section 8.1, "Job States", on page 361	
			B	Array job has at least one subjob running
			E	Job is exiting after having run
			F	Job is finished
			H	Job is held
			M	Job was moved to another server
			Q	Job is queued
			R	Job is running
			S	Job is suspended
			T	Job is being moved to new location
			U	Cycle-harvesting job is suspended due to keyboard activity
			W	Job is waiting for its submitter-assigned start time to be reached
			X	Subjob has completed execution or has been deleted
Queue	16	15	The queue in which the job resides	

2.55.3.2 Job Status in Long Format

Trigger: the -f option.

If you specify the -f (full) option, full job status information for each job is displayed in this order:

- The job ID
- Each job attribute, one to a line
- The job's submission arguments
- The job's executable, in JSDL format
- The executable's argument list, in JSDL format

The job attributes are listed as *<name> = <value>* pairs. This includes the exec_host and exec_vnode strings. The full output can be very large.

The exec_host string has this format:

<host1>/<T1><P1>[+<host2>/<T2>*<P2>+...]*

where

T1 is the task slot number (the index) of the job on host1.

P1 is the number of processors allocated to the job from host1. The number of processors allocated does not appear if it is 1.

The exec_vnode string has the format:

(<vnode1>:ncpus=<N1>:mem=<M1>)[+(<vnode2>:ncpus=<N2>:mem=<M2>)+...]

where

N1 is the number of CPUs allocated to that job on *vnode1*.

M1 is the amount of memory allocated to that job on *vnode1*.

2.55.3.3 Job Status in Alternate Format

Triggers: any of the -a, -i, -G, -H, -M, -n, -r, -s, -T, or -u <user list> options.

The qstat command displays job status in alternate format if you specify any of the -a, -i, -G, -H, -M, -n, -r, -s, -T, or -u <user list> options. Jobs are displayed one to a line. If jobs are running and the -n option is specified, or if jobs are finished or moved and the -H and -n options are specified, there is a second line for the exec_host string.

2.55.3.3.i Job Status Alternate Format Output Columns

Alternate format job status output contains the following columns:

```
                                                  Req'd  Req'd   Elap
Job ID Username Queue Jobname SessID NDS TSK Memory Time  S Time
------ -------- ----- ------- ------ --- --- ------ ----- - ----
```

Description of columns:

Table 2-28: Description of Alternate Format Job Status Columns

Column	Width without -w	Width with -w	Description
Job ID	15 (20 when max_job_sequence_id > 10 million)	30	The job ID assigned by PBS
Username	8	15	Username of job owner
Queue	8	15	Queue in which the job resides
Jobname	10	15	Job name specified by submitter
SessID	6	8	Session ID. Appears only if the job is running
NDS	3	4	Number of chunks or vnodes requested by the job
TSK	3	5	Number of CPUs requested by the job
Req'd Memory	6	6	Amount of memory requested by the job
Req'd Time	5	5	If CPU time is requested, shows CPU time. Otherwise, shows walltime
S	1	1	The job's state; see "States" on page 361 for states
Elap Time or Est Start Time	5	5	If CPU time is requested, shows CPU time. Otherwise, shows walltime. If you use the `-P` option, displays estimated start time for queued jobs, replacing the *Elap Time* field with the *Est Start Time* field.

2.55.3.4 Grouping Jobs and Sorting by ID

Trigger: the `-E` option.

You can use the `-E` option to sort and group jobs in the output of `qstat`. The `-E` option groups jobs by server and displays each group by ascending ID. This option also improves `qstat` performance. The following table shows how the `-E` option affects the behavior of `qstat`:

Table 2-29: How -E Option Affects qstat Output

How qstat is Used	Result Without -E	Result With -E
`qstat` (no job ID specified)	Queries the default server and displays result	No change in behavior; same as without `-E` option
`qstat <list of job IDs from single server>`	Displays results in the order specified	Displays results in ascending ID order
`qstat <job IDs at multiple servers>`	Displays results in the order they are specified	Groups jobs by server. Displays each group in ascending order

2.55.4 Displaying Queue Status

2.55.4.1 Queue Status in Default Format

Trigger: the -Q option by itself.

The qstat command displays queue status in default format if the only option is -Q. Queue status is displayed one queue to a line, with these column headers:

```
Queue       Max  Tot  Ena  Str Que  Run  Hld  Wat  Trn  Ext  Type
----------- ---- ---- ---- --- ---- ---- ---- ---- ---- ---- ----
```

Description of columns:

Table 2-30: Description of Default Queue Status Columns

Column	Description
Queue	Queue name
Max	Maximum number of jobs allowed to run concurrently in this queue
Tot	Total number of jobs in the queue
Ena	Whether the queue is enabled or disabled
Str	Whether the queue is started or stopped
Que	Number of queued jobs
Run	Number of running jobs
Hld	Number of held jobs
Wat	Number of waiting jobs
Trn	Number of jobs being moved (transiting)
Ext	Number of exiting jobs
Type	Type of queue: execution or routing

2.55.4.2 Queue Status in Long Format

Trigger: the -Q and -f options together.

If you specify the -f (full) option with the -q option, full queue status information for each queue is displayed starting with the queue name, followed by each attribute, one to a line, as <*name*> = <*value*> pairs.

2.55.4.2.i Queue Status: Alternate Format

Triggers: any of the -q, -G, or -M options.

The qstat command displays queue status in the alternate format if you specify any of the -q, -G, or -M options. Queue status is displayed one queue to a line, and the lowest line contains totals for some columns.

These are the alternate format queue status column headers:

```
Queue   Memory CPU Time Walltime Node Run Que Lm State
------- ------ -------- -------- ---- --- --- -- -----
```

Description of columns:

Table 2-31: Description of Queue Alternate Status Columns

Column	Description
Queue	Queue name
Memory	Maximum amount of memory that can be requested by a job in this queue
CPU Time	Maximum amount of CPU time that can be requested by a job in this queue
Walltime	Maximum amount of walltime that can be requested by a job in this queue
Node	Maximum number of vnodes that can be requested by a job in this queue
Run	Number of running and suspended jobs. Lowest row is total number of running and suspended jobs in all the queues shown
Que	Number of queued, waiting, and held jobs. Lowest row is total number of queued, waiting, and held jobs in all the queues shown
Lm	Maximum number of jobs allowed to run concurrently in this queue
State	State of this queue: *E* (enabled) or *D* (disabled), and *R* (running) or *S* (stopped)

2.55.5 Displaying Server Status

2.55.5.1 Server Status in Default Format:

Trigger: the `-B` option.

The `qstat` command displays server status if the only option given is `-B`.

Column headers for default server status output:

```
Server   Max   Tot   Que   Run   Hld   Wat   Trn   Ext   Status
-------- ----- ----- ----- ----- ----- ----- ----- ----- ------
```

Description of columns:

Table 2-32: Description of Server Status Default Display Columns

Column	Description
Server	Name of server
Max	Maximum number of jobs allowed to be running concurrently on the server
Tot	Total number of jobs currently managed by the server
Que	Number of queued jobs
Run	Number of running jobs
Hld	Number of held jobs
Wat	Number of waiting jobs

Table 2-32: Description of Server Status Default Display Columns

Column	Description
Trn	Number of transiting jobs
Ext	Number of exiting jobs
Status	Status of the server

2.55.5.2 Server Status in Long Format

Trigger: the `-f` option.

If you specify the `-f` (full) option, displays full server status information starting with the server name, followed by each server attribute, one to a line, as <*name*> = <*value*> pairs. Includes PBS version information.

2.55.6 Options to `qstat`

2.55.6.1 Generic Job Status Options

-E

Groups jobs by server and displays jobs sorted by ascending ID. When `qstat` is presented with a list of jobs, jobs are grouped by server and each group is displayed by ascending ID. This option also improves `qstat` performance. See section 2.55.3.4, "Grouping Jobs and Sorting by ID", on page 204.

2.55.6.2 Default Job Status Options

The following options cause job status information to be displayed in default format:

-J

Displays status information for job arrays (not subjobs). When used with the `-t` option, displays status information for subjobs only.

-t

Displays status information for jobs, job arrays, and subjobs. When used with `-J` option, displays status information for subjobs only.

-p

The *Time Use* column is replaced with the percentage completed for the job. For a job array this is the percentage of subjobs completed. For a normal job, it is the percentage of allocated CPU time used.

-x

Displays status information for finished and moved jobs in addition to queued and running jobs.

2.55.6.3 Alternate Job Status Options

The following options cause job status information to be displayed in alternate format:

-a

All queued and running jobs are displayed. If a *destination* is specified, information for all jobs at that *destination* is displayed. If a *job ID* is specified, information about that job is displayed. When using this option with the `-n` or `-s` options, always specify this option before the `-n` or `-s` options, otherwise they will not take effect.

-H

Without a job identifier, displays information for all finished or moved jobs. If a *job ID* is given, displays information for that job regardless of its state. If a *destination* is specified, displays information for finished or moved jobs, or specified job(s), at *destination*.

-i

If a *destination* is given, information for queued, held or waiting jobs at that *destination* is displayed. If a *job ID* is given, information about that job is displayed regardless of its state.

-n

The exec_host string is listed on the line below the basic information. If the `-1` option is given, the exec_host string is listed on the end of the same line. If using the `-a` option with this option, always specify the `-n` option after -a, otherwise the `-n` option does not take effect.

-r

If a *destination* is given, information for running or suspended jobs at that *destination* is displayed. If a *job ID* is given, information about that job is displayed regardless of its state.

-s

Any comment added by the administrator or scheduler is shown on the line below the basic information. If the `-1` option is given, the comment string is listed on the end of the same line. If using the `-a` option with this option, always specify the `-s` option after `-a`, otherwise the `-s` option does not take effect.

-T

Displays estimated start time for queued jobs, replacing the *Elap Time* field with the *Est Start Time* field. Jobs with earlier estimated start times are displayed before those with later estimated start times.

Running jobs are displayed before other jobs. Running jobs are sorted by their stime attribute (start time).

Queued jobs whose estimated start times are unset (estimated.start_time = *unset*) are displayed after those with estimated start times, with the unset value shown as a double dash ("--"). Queued jobs with estimated start times in the past are treated as if their estimated start times are unset.

If a job's estimated start time cannot be calculated, the start time is shown as a question mark ("?").

Time displayed is local to the `qstat` command. Current week begins on Sunday.

The following table shows the format for the *Est Start Time* field when the -w option is not used:

Table 2-33: Format for Estimated Start Time Field without -w Option

Format	Job Estimated Start Time	Example
<HH>:<MM>	Today	`15:34`
<2-letter weekday> <HH>	Within 7 days, but after today	`We 15`
<3-letter month name>	This calendar year, but after this week	`Feb`
<YYYY>	Less than or equal to 5 years from today, after this year	`2018`
>5yrs	More than 5 years from today	`>5yrs`

The following table shows the format for the *Est Start Time* field when the -w option is used:

Table 2-34: Format for Estimated Start Time Field with -w Option

Format	Job Estimated Start Time	Example
Today <HH>:<MM>	Today	`Today 13:34`
<Day> <HH>:<MM>	This week, but after today	`Wed 15:34`
<Day> <Month> <Daynum> <HH>:<MM>	This year, but after this week	`Wed Feb 10 15:34`
<Day> <Month> <Daynum> <YYYY> <HH>:<MM>	After this year	`Wed Feb 10 2011 15:34`

When used with the -f option, prints the full timezone-qualified start time.

Estimated start time information can be made unavailable to unprivileged users; in this case, the estimated start time appears to be unset.

-u <user list>

If a *destination* is given, status for jobs at that *destination* owned by users in *user list* is displayed. If a *job ID* is given, status information for that job is displayed regardless of the job's ownership.

Format: *<username>[@<hostname>][, <username>[@<hostname>], ...]* in comma-separated list.

Hostnames may be wildcarded, but not domain names. When no hostname is specified, *username* is for any host.

-w

Can be used with job status in default and alternate formats. Allows display of wider fields up to 120 characters. See section 2.55.3.1, "Job Status in Default Format", on page 201 and section 2.55.3.3, "Job Status in Alternate Format", on page 203 for column widths.

This option is different from the -w option used with the -f long-format option.

-1 (hyphen one)

Reformats qstat output to a single line. Can be used only in conjunction with the -n and/or -s options.

2.55.6.4 Queue Status Options

-Q

Displays queue status in default format. Operands must be *destinations*.

-q

Displays queue status in alternate format. Operands must be *destinations*.

2.55.6.5 Server Status Options

-B

Display server status. Operands must be names of servers.

2.55.6.6 Job, Queue, and Server Status Options

-f [-w]

Full display for long format. Job, subjob, queue, or server attributes displayed one to a line.

JSON output:

PBS reports resources_used values for resources that are created or set in a hook as JSON strings in the output of qstat -f.

If MoM returns a JSON object (a Python dictionary), PBS reports the value as a string in single quotes:

```
resources_used.<resource_name> = '{ <MoM JSON item value>, <MoM JSON item value>, <MoM JSON item value>, ..}'
```

Example: MoM returns { "a":1, "b":2, "c":1,"d": 4} for resources_used.foo_str. We get:

```
resources_used.foo_str='{"a": 1, "b": 2, "c":1,"d": 4}'
```

If MoM returns a value that is not a valid JSON object, the value is reported verbatim.

Example: MoM returns "hello" for resources_used.foo_str. We get:

```
resources_used.foo_str="hello"
```

Optional -w prints each attribute on one unbroken line. Feed characters are converted:

- Newline is converted to backslash concatenated with "n", resulting in "\n"
- Form feed is converted to backslash concatenated with "f", resulting in "\f"

This -w is independent of the -w job output option used with default and alternate formats.

-F dsv [-D <delimiter>]

Prints output in delimiter-separated value format. The default *delimiter* is a pipe ("|"). You can specify a character or a string *delimiter* using the -D argument to the -F dsv option. For example, to use a comma as the delimiter:

```
qstat -f -F dsv -D,
```

If the delimiter itself appears in a value, it is escaped:

- On Linux, the delimiter is escaped with a backslash ("\").
- On Windows, the delimiter is escaped with a caret ("^").

Feed characters are converted:

- Newline is converted to backslash concatenated with "n", resulting in "\n"
- Form feed is converted to backslash concatenated with "f", resulting in "\f"

A newline separates each job from the next. Using newline as the delimiter leads to undefined behavior.

Example of getting output in delimiter-separated value format:

```
qstat -f -Fdsv
Job Id: 1.vbox|Job_Name = STDIN|Job_Owner = root@vbox|job_state = Q|queue = workq|server =
    vbox|Checkpoint = u|ctime = Fri Nov 11 17:57:05 2016|Error_Path = ...
```

-F json

Prints output in JSON format (http://www.json.org/).

Attribute output is preceded by timestamp, PBS version, and PBS server hostname.

Example:

```
qstat -f -F json
{
    "timestamp":1479277336,
    "pbs_version":"14.1",
    "pbs_server":"vbox",
    "Jobs":{
        "1.vbox":{
            "Job_Name":"STDIN",
            "Job_Owner":"root@vbox",
            "job_state":"Q",
...
```

-G

Shows size in gigabytes. Triggers alternate format.

-M

Shows size in megawords. A word is considered to be 8 bytes. Triggers alternate format.

2.55.6.7 Version Information

--version

The qstat command returns its PBS version information and exits. This option can only be used alone.

2.55.7 Operands

2.55.7.1 Job Identifier Operands

The *job ID* is assigned by PBS at submission. Job IDs are used only with job status requests. Status information for specified job(s) is displayed.

Input formats:

Job ID:

<sequence number>[.<server name>][@<server name>]

Job array ID:

<sequence number>[][.<server name>][@<server name>]

Subjob ID:

<sequence number>[<index>][.<server name>][@<server name>]

Range of subjobs:

<sequence number>[<index start>-<index end>][.<server name>][@<server name>]

Note that some shells require that you enclose a job array identifier in double quotes.

You can use a list of jobs generated as the output of the `qselect` command as the input to the `qstat` command. For example, to get a detailed listing of running jobs:

```
qstat -f $(qselect -s R)
```

2.55.7.2 Destination Operands

Name of queue, name of server, or name of queue at a specific server. Formats:

<queue name>

Specifies name of queue for job or queue display.

- When displaying job status, PBS displays status for all jobs in the specified queue at the default server.
- When displaying queue status, PBS displays status for the specified queue at the default server.

<queue name>@<server name>

Specifies name of queue at server for job or queue display.

- When displaying job status, PBS displays status for all jobs in the specified queue at the specified server.
- When displaying queue status, PBS displays status for the specified queue at the specified server.

@<server name>

Specifies server name for job or queue display.

- When displaying job status, PBS displays status for all jobs at all queues at the specified server.
- When displaying queue status, PBS displays status for all queues at the specified server.

<server name>

Specifies server name for server display.

- When displaying server status (with the `-B` option) PBS displays status for the specified server.

2.55.8 Standard Error

The `qstat` command writes a diagnostic message to standard error for each error occurrence.

2.55.9 Exit Status

Zero
: Upon successful processing of all operands

Greater than zero
: If any operands could not be processed

2.55.10 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide, "Attributes" on page 277

2.56 qstop

Prevents PBS jobs in the specified queue from being scheduled or routed

2.56.1 Synopsis

qstop <destination> [<destination> ...]

qstop --version

2.56.2 Description

If *destination* is an execution queue, the `qstop` command stops a scheduler from scheduling jobs residing in *destination*. If *destination* is a routing queue, the server stops routing jobs from that queue. Sets the value of the queue's started attribute to *False*.

2.56.2.1 Required Privilege

You must have PBS Operator or Manager privilege to run this command.

2.56.3 Options

--version

The `qstop` command returns its PBS version information and exits. This option can only be used alone

2.56.4 Operands

The `qstop` command accepts one or more space-separated *destination* operands. The operands take one of three forms:

<queue name>

Stops scheduling or routing from the specified queue.

@<server name>

Stops scheduling or routing from all queues at the specified server.

<queue name>@<server name>

Stops scheduling or routing from the specified queue at the specified server.

To stop scheduling at all queues at the default server, use the `qmgr` command:

```
Qmgr: set queue @default started=false
```

2.56.5 Standard Error

The `qstop` command writes a diagnostic message to standard error for each error occurrence.

2.56.6 Exit Status

Zero

Upon successful processing of all operands presented to the `qstop` command

Greater than zero

If the `qstop` command fails to process any operand

2.56.7 See Also

The PBS Professional Administrator's Guide, "qmgr" on page 152, "qstart" on page 198

2.57 qsub

Submits a job to PBS

2.57.1 Synopsis

qsub [-a <date and time>] [-A <account string>] [-c <checkpoint spec>] [-C <directive prefix>] [-e <path>] [-f] [-h] [-I [-G [-- <GUI application/script>]] | [-X]] [-j <join>] [-J <range> [%<max subjobs]] [-k <discard>] [-l <resource list>] [-m <mail events>] [-M <user list>] [-N <name>] [-o <path>] [-p <priority>] [-P <project>] [-q <destination>] [-r <y | n>] [-R <remove options>] [-S <path list>] [-u <user list>] [-v <variable list>] [-V] [-W <additional attributes>] [-z] [- | <script> | -- <executable> [<arguments to executable>]]

qsub --version

2.57.2 Description

You use the `qsub` command to submit a batch job to PBS. Submitting a PBS job specifies a task, requests resources, and sets job attributes.

The `qsub` command can read from a job script, from standard input, or from the command line.

- To use a job script:

  qsub [<options>] <job script containing directives and executable>

  qsub [<options>] <directives> <job script containing other directives and executable>
- To submit from the command line:

  qsub [<options>] <directives> -- <executable> <arguments to executable>
- To submit from standard input:

  qsub <return>

  <directives>

  <executable>

  <CTRL-D>

When the user has submitted the job, PBS returns the job identifier for that job. For a job, this is of the form:

<sequence number>.<server name>

For an array job, this is of the form:

<sequence number>[].<server name>

During execution, jobs can be interactive or non-interactive. Interactive jobs are not rerunnable, and if they are blocking, you cannot use their exit status.

Jobs are run as the user and group who submitted the job.

2.57.2.1 Background Process

By default, on the first invocation, `qsub` spawns a background process to manage communication with the PBS server. Later invocations of `qsub` attempt to communicate with this background process. Under certain circumstances, calls to `qsub` when it uses the background process can result in communication problems. You can prevent `qsub` from spawning a background process by using the `-f` option, although this can degrade performance.

2.57.2.2 Where PBS Puts Job Files

By default, PBS copies the `stdout` and `stderr` files from the job back to the current working directory where the `qsub` command is executed. However, you can specify the output paths using the `-o` and `-e` options. You can also specify which and whether these files should be kept on the execution host via the `-k` option, or deleted, using the `-R` option.

See the `-k`, `-o`, `-e`, and `-R` options, and "Managing Output and Error Files", on page 42 of the PBS Professional User's Guide.

2.57.2.3 Submitting Jobs By Using Job Scripts

To submit a PBS job by using a script, you specify a job script on the command line:

qsub [<options>] <script name>

For example:

```
qsub myscript.sh
```

Job scripts are run as the user and group who submitted the job. Job scripts can be written in Python, Linux shells such as `csh` and `sh`, the Windows command batch language, Perl, etc.

A PBS job script consists of the following:

- Optional shell specification
- Any PBS directives
- The user's tasks: programs, commands, or applications
- Optional comments

  Under Windows, comments can contain only ASCII characters. See the PBS Professional User's Guide.

2.57.2.3.i Using Shells and Interpreters

By default, PBS uses your login shell to run your script. You can optionally specify a different shell or interpreter to run your script:

- Via the `-S` option to `qsub`:

  qsub -S <path to shell> <script name>

  For example:

  ```
  qsub -S /bin/bash myscript.sh
  ```

- You can specify a different interpreter in the first line of your script. For example:

  ```
  cat myscript.sh
  #!/bin/bash
  #PBS -N MyHelloJob
  echo "Hello"
  ```

2.57.2.3.ii Python Job Scripts

You can use the same Python script under Linux or under Windows, if the script is written to be portable. PBS includes a Python package, allowing Python job scripts to run; you do not need to install Python. You can include PBS directives in a Python job script as you would in a Linux shell script. Python job scripts can access Win32 APIs, including the following modules:

Win32api

Win32con

Pywintypes

Example 2-25: We have a Python job script that includes PBS directives:

```
cat myjob.py
#!/usr/bin/python
#PBS -l select=1:ncpus=3:mem=1gb
#PBS -N HelloJob
print "Hello"
```

As long as the first line of the script is "#!/usr/bin/python" or similar, you don't need to to anything special to run a Python script:

qsub <script name>

For example:

```
qsub myscript.py
```

To run a Python job script under Windows, use the path to the pbs_python executable on the execution host:

qsub -S <pbs_python path on execution host> <script name>

For example:

```
qsub -S %PBS_EXEC%\bin\pbs_python.exe <script name>
```

If the script pathname contains spaces, it must be quoted, for example:

```
qsub -S "C:\Program Files\PBS\bin\pbs_python.exe" <script name>
```

2.57.2.3.iii Linux Shell Job Scripts

Example 2-26: We have a Linux job script named "weatherscript" for a job named "Weather1" which runs the executable "weathersim" on Linux:

```
#!/bin/sh
#PBS -N Weather1
#PBS -l walltime=1:00:00
/usr/local/weathersim
```

To submit the job, the user types:

```
qsub weatherscript <return>
```

2.57.2.3.iv Windows Command Job Scripts

Example 2-27: We have a script named "weather.exe" for a job named "Weather1" which runs under Windows:

```
#PBS -N Weather1
#PBS -l walltime=1:00:00
weathersim.exe
```

To submit the job, the user types:

```
qsub weather.exe <return>
```

In Windows, if you use notepad to create a job script, the last line does not automatically get newline-terminated. Be sure to put one explicitly, otherwise, PBS job will get the following error message:

```
More?
```

when the Windows command interpreter tries to execute that last line.

2.57.2.4 Submitting Jobs From Standard Input

To submit a PBS job by typing job specifications at the command line, you type:

qsub [<options>] [-] <return>

then type any directives, then any tasks, followed by:

- Linux: `CTRL-D` on a line by itself
- Windows: `CTRL-Z <return>`

to terminate the input.

The `qsub` command behaves the same both with and without the dash operand.

For example, on Linux:

```
qsub <return>
#PBS -N StdInJob
#PBS -l walltime=1:00:00
sleep 100
<CTRL-D>
```

2.57.2.5 Submitting Job Directly by Specifying Executable on Command Line

To submit a job directly, you specify the executable on the command line:

qsub [<options>] -- <executable> [<arguments to executable>] <return>

When you run `qsub` this way, it runs the *executable* directly. It does not start a shell, so no shell initialization scripts are run, and execution paths and other environment variables are not set. There is not an easy way to run your command in a different directory. You should make sure that environment variables are set correctly, and you will usually have to specify the full path to the command.

On Linux, specify the full path to the executable.

Example 2-28: To run `myprog` with the arguments *a* and *b*:

```
qsub -- myprog a b <return>
```

Example 2-29: To run `myprog` with the arguments *a* and *b*, naming the job "JobA":

```
qsub -N JobA -- myprog a b <return>
```

Example 2-30: To run `myprog` on a Linux system with the arguments *a* and *b*, naming the job "JobA":

```
qsub -N JobA -- <path to myprog>/myprog a b <return>
```

2.57.2.6 Requesting Resources and Placing Jobs

Requesting resources includes setting limits on resource usage and controlling how the job is placed on vnodes.

Resources are requested by using the `-l` option, either in job-wide requests using *<resource name>=<value>* pairs, or in chunks inside of *selection statements*. See Chapter 5, "List of Built-in Resources", on page 259.

Job-wide *<resource name>=<value>* requests are of the form:

-l <resource name>=<value>[,<resource name>=<value> ...]

The selection statement is of the form:

-l select=[<N>:]<chunk>[+[<N>:]<chunk> ...]

where *N* specifies how many of that chunk, and a *chunk* is of the form:

<resource name>=<value>[:<resource name>=<value> ...]

You choose how your chunks are placed using the *place statement*. The *place statement* can contain the following elements, in any order:

-l place=[<arrangement>][: <sharing>][: <grouping>]

where

arrangement

Whether this chunk is willing to share this vnode or host with other chunks from the same job. One of *free* | *pack* | *scatter* | *vscatter*

sharing

Whether this this chunk is willing to share this vnode or host with other jobs. One of *excl* | *shared* | *exclhost*

grouping

Whether the chunks from this job should be placed on vnodes that all have the same value for a resource. Can have only one instance of *group=<resource name>*

free

Place job on any vnode(s).

pack

All chunks are taken from one host.

scatter

Only one chunk with any MPI processes is taken from a host. A chunk with no MPI processes may be taken from the same vnode as another chunk.

vscatter

Only one chunk is taken from any vnode. Each chunk must fit on a vnode.

excl

Only this job uses the vnodes chosen.

shared

This job can share the vnodes chosen.

exclhost

The entire host is allocated to the job.

group=<resource name>

Chunks are grouped according to a resource. All vnodes in the group must have a common value for *resource*, which can be either the built-in resource host or a custom vnode-level resource.

resource name must be a string or a string array.

The place statement cannot begin with a colon. Colons are delimiters; use them only to separate parts of a place statement, unless they are quoted inside resource values.

Note that vnodes can have sharing attributes that override job placement requests. See section 6.10, “Vnode Attributes”, on page 320.

For more on resources, resource requests, usage limits, and job placement, see "Using PBS Resources" on page 227 in the PBS Professional Administrator’s Guide and "Allocating Resources & Placing Jobs", on page 51 of the PBS Professional User’s Guide.

2.57.2.6.i Caveats for Requesting Resources

Do not mix old-style resource or vnode specifications with the new *select* and *place* statements. Do not use one in a job script and the other on the command line. Mixing the two will result in an error.

You cannot submit a job requesting a custom resource which has been created to be invisible or read-only for unprivileged users, regardless of your privilege. A Manager or Operator can use the `qalter` command to change a job's request for this kind of custom resource.

2.57.2.7 Setting Attributes

The job submitter sets job attributes by giving options to the `qsub` command or by using PBS directives. Most `qsub` options set a job attribute, and have a corresponding PBS directive with the same syntax as the option. Attributes set via command-line options take precedence over those set using PBS directives. See the PBS Professional User's Guide, `or` section 6.11, “Job Attributes”, on page 327.

2.57.2.8 Running Your Job on First Available Resources

You may want to run a job on whichever resources become available first, even if the job could run on other sets of resources. You may want to start a flexible job as soon as possible on a smaller set of resources rather than waiting longer for a larger set of resources, or you may prefer certain resources but be able to use others (for example, you might prefer a specific processor, but still be able to run on another if that is all that's available).

If you submit a set of jobs where each job has a "runone" dependency on the others, PBS runs only one of the jobs in the "runone set". PBS automatically groups the jobs into a runone set. The jobs in a runone set can run different scripts.

When any of the jobs in the set starts, PBS applies a system hold to the others. The hold on the other jobs is released when the running job is requeued:

- Via `qrerun`
- When node fail requeue is triggered

The other jobs in the set are deleted:

- When a job ends, regardless of its exit status
- When the running job is deleted

To identify a job as a member of the set, give it a "runone" dependency on the previously-submitted member of the set. For example, we have three jobs, each of which runs on different resources. To submit these three jobs as a runone set:

```
qsub -lselect=200:ncpus=16 -lwalltime=1:00:00 myscript.sh
10.myserver
qsub -lselect=100:ncpus=16 -lwalltime=2:00:00 -Wdepend=runone:10 myscript.sh
11.myserver
qsub -lselect=50:ncpus=16 -lwalltime=4:00:00 -Wdepend=runone:10 myscript.sh
12.myserver
```

2.57.2.9 Changing `qsub` Behavior

The behavior of the `qsub` command may be affected by the server's default_qsub_arguments attribute. This attribute can set the default for any job attribute. The default_qsub_arguments server attribute is settable by the administrator, and is overridden by command-line arguments and script directives. See section 6.6, “Server Attributes”, on page 281.

The behavior of the `qsub` command may also be affected by any site hooks. Site hooks can modify the job's attributes, change its routing, etc.

2.57.3 Options to `qsub`

-a <date and time>

Point in time after which the job is eligible for execution. Given in pairs of digits. Sets job's Execution_Time attribute to *date and time*.

Format: *datetime,* expressed as *[[[[CC]YY]MM]DD]hhmm[.SS]*

where *CC* is the century, *YY* is the year, *MM* is the month, *DD* is the day of the month, *hh* is the hour, *mm* is the minute, and *SS* is the seconds.

Each portion of the date defaults to the current date, as long as the next-smaller portion is in the future. For example, if today is the 3rd of the month and the specified day *DD* is the 5th, the month *MM* is set to the current month.

If a specified portion has already passed, the next-larger portion is set to one after the current date. For example, if the day *DD* is not specified, but the hour hh is specified to be 10:00 a.m. and the current time is 11:00 a.m., the day *DD* is set to tomorrow.

-A <account string>

Accounting string associated with the job. Used for labeling accounting data. Sets job's Account_Name attribute to *account string*.

Format: *String*

-c <checkpoint spec>

Determines when the job will be checkpointed. Sets job's Checkpoint attribute to *checkpoint spec*. An $action script is required to checkpoint the job.

See "Using Checkpointing", on page 115 of the PBS Professional User's Guide.

The argument *checkpoint spec* can take one of the following values:

c

Checkpoint at intervals, measured in CPU time, set on job's execution queue. If there is no interval set at the queue, the job is not checkpointed

c=<minutes of CPU time>

Checkpoint at intervals of specified number of minutes of job CPU time. This value must be greater than zero. If the interval specified is less than that set on the job's execution queue, the queue's interval is used.

Format: *Integer*

w

Checkpoint at intervals, measured in walltime, set on job's execution queue. If there is no interval set at the queue, the job is not checkpointed.

w=<minutes of walltime>

Checkpoint at intervals of the specified number of minutes of job walltime. This value must be greater than zero. If the interval specified is less than that set on the job's execution queue, the queue's interval is used.

Format: *Integer*

n

No checkpointing.

s

Checkpoint only when the server is shut down.

u

Unset. Defaults to behavior when *interval* argument is set to *s*.

Default: *u*

Format: *String*

-C <directive prefix>

Defines the prefix identifying a PBS directive. Default prefix is "*#PBS*".

If the *directive prefix* argument is a null string, `qsub` does not scan the script file for directives. Overrides the PBS_DPREFIX environment variable and the default. The string "PBS_DPREFIX" cannot be used as a PBS directive. Length limit: 4096 characters.

-e <path>

Path to be used for the job's standard error stream. Sets job's Error_Path attribute to *path*. The *path* argument is of the form:

[<hostname>:]<path>

The *path* is interpreted as follows:

path

If *path* is relative, it is taken to be relative to the current working directory of the `qsub` command, where it is executing on the current host.

If *path* is absolute, it is taken to be an absolute path on the current host where the `qsub` command is executing.

hostname:path

If *path* is relative, it is taken to be relative to the user's home directory on the host named *hostname*.

If *path* is absolute, it is an absolute path on the host named *hostname*.

If *path* does not include a filename, the default filename has the form *<job ID>.ER*

If the `-e` option is not specified, PBS copies the standard error to the current working directory where the `qsub` command was executed, and writes standard error to the default filename, which has this form:

<job name>.e<sequence number>

If you use a UNC path for output or error files, the *hostname* is optional. If you use a non-UNC path, the *hostname* is required.

This option is overridden by the `-k` option.

-f

Prevents `qsub` from spawning a background process. By default, `qsub` spawns a background process to manage communication with the PBS server. When this option is specified, the `qsub` process connects directly to the server and no background process is created.

NOTE: Use of this option degrades performance of `qsub` when calls to `qsub` are made in rapid succession.

-G [<path to GUI application or script>]

Starts a GUI session. When no application or script is provided, starts a GUI-enabled interactive shell. When an application or script is provided, starts the GUI application or script. Use full path to application or script unless the path is part of the user's PATH environment variable on the execution host. When submission and execution hosts are different, this uses a remote viewer.

Session is terminated when remote viewer, GUI application, or interactive shell is terminated, or when job is deleted.

Can be used only with interactive jobs (the `-I` option).

Available only under Windows.

-h

Applies a *User* hold to the job. Sets the job's Hold_Types attribute to "*u*".

-I

Job is to be run interactively. Sets job's interactive attribute to *True*. The job is queued and scheduled as any PBS batch job, but when executed, the standard input, output, and error streams of the job are connected to the terminal session in which `qsub` is running. If a job script is given, only its directives are processed. When the job begins execution, all input to the job is taken from the terminal session. See the PBS Professional User's Guide for additional information on interactive jobs.

Interactive jobs are not rerunnable.

Job arrays cannot be interactive.

When used with `-Wblock=true`, no exit status is returned.

-j <join>

Specifies whether and how to join the job's standard error and standard output streams. Sets job's Join_Path attribute to *join*.

Default: *n*; not merged

The *join* argument can take the following values:

Table 2-35: Sub-options to -j Option

Suboption	Meaning
oe	Standard error and standard output are merged into standard output.
eo	Standard error and standard output are merged into standard error.
n	Standard error and standard output are not merged.

-J <range> [%<max subjobs>]

Makes this job an array job. Sets job's array attribute to *True*.

Use the *range* argument to specify the indices of the subjobs of the array. *range* is specified in the form *X-Y[:Z]* where *X* is the first index, *Y* is the upper bound on the indices, and *Z* is the stepping factor. For example, 2-7:2 will produce indices of *2*, *4*, and *6*. If *Z* is not specified, it is taken to be *1*. Indices must be greater than or equal to zero.

Use the optional *%max subjobs* argument to set a limit on the number of subjobs that can be running at one time. This sets the value of the max_run_subjobs job attribute to the specified maximum.

Job arrays are always rerunnable.

-k <discard>

Specifies whether and which of the standard output and standard error streams is left behind on the execution host, or written to their final destination. Sets the job's Keep_Files attribute to *discard*.

k {e | o | eo | oe | n}

For the `e`, `o`, `eo`, `oe`, or `n` suboptions, overrides `-o <output path>` and `-e <error path>` options.

kd {e | o | eo | oe}

When used with the -d suboption, specifies that output and/or error files are written directly to the final destination. Requires e and/or o sub-options.

Default: *n*; neither is retained, and files are not written directly to final destinations.

In the case where output and/or error is retained on the execution host in a job-specific staging and execution directory created by PBS, these files are deleted when PBS deletes the directory.

The *discard* argument can take the following values:

Table 2-36: Sub-options to discard Option

Suboption	Meaning
e	The standard error stream is retained on the execution host, in the job's staging and execution directory. The filename is *<job name>.e<sequence number>*
o	The standard output stream is retained on the execution host, in the job's staging and execution directory. The filename is *<job name>.o<sequence number>*
eo, oe	Both standard output and standard error streams are retained on the execution host, in the job's staging and execution directory.
d<e and/or o>	Output and/or error are written directly to their final destination. Overrides action of leaving files on execution host. Requires e and/or o sub-options.
n	Neither stream is retained.

-l <resource list>

Allows the user to request resources and specify job placement. Sets job's Resource_list attribute to *resource list*. Requesting a resource places a limit on its usage.

For how to request resources and place jobs, see section 2.57.2.6, “Requesting Resources and Placing Jobs”, on page 219.

-m <mail events>

Specifies the set of conditions under which mail about the job is sent. Sets job's Mail_Points attribute to *mail events*. The *mail events* argument can be one of the following:

- The single character "*n*"
- Any combination of "*a*", "*b*", and "*e*", with optional "*j*"

The following table lists the sub-options to the -m option:

Table 2-37: Sub-options to m Option

Suboption	Meaning
n	No mail is sent.
a	Mail is sent when the job is aborted by PBS.
b	Mail is sent when the job begins execution.
e	Mail is sent when the job terminates.
j	Mail is sent for subjobs. Must be combined with one or more of a, b, or e options

Format: *String*

Syntax: *n | [j](one or more of a, b, e)*

Example: -m ja

Default value: *"a"*

-M <user list>

List of users to whom mail about the job is sent. Sets job's Mail_Users attribute to *user list*.

The *user list* argument has the form:

<username>[@<hostname>][,<username>[@<hostname>],...]

Default: Job owner

-N <name>

Sets job's Job_Name attribute and name to *name*.

Format: *Job Name*; see "Job Name, Job Array Name" on page 355

Default: if a script is used to submit the job, the job's name is the name of the script. If no script is used, the job's name is "*STDIN*".

-o <path>

Path to be used for the job's standard output stream. Sets job's Output_Path attribute to *path*. The *path* argument has the form:

[<hostname>:]<path>

The *path* is interpreted as follows:

path

If *path* is relative, it is taken to be relative to the current working directory of the `qsub` command, where it is executing on the current host.

If *path* is absolute, it is taken to be an absolute path on the current host where the `qsub` command is executing.

hostname:path

If *path* is relative, it is taken to be relative to the user's home directory on the host named *hostname*.

If *path* is absolute, it is an absolute path on the host named *hostname*.

If *path* does not include a filename, the default filename has the form *<job ID>.OU*

If the -o option is not specified, PBS copies the standard output to the current working directory where the qsub command was executed, and writes standard output to the default filename, which has this form:

<job name>.o<sequence number>

If you use a UNC path, the hostname is optional. If you use a non-UNC path, the hostname is required.

This option is overridden by the -k option.

-p <priority>

Priority of the job. Sets job's Priority attribute to *priority.*

Format: Host-dependent integer

Range: [-1024, +1023] inclusive

Default: *Zero*

-P <project>

Specifies a project for the job. Sets job's project attribute to *project*.

Format: *Project Name*; see "Project Name" on page 357

Default value: "*_pbs_project_default*".

-q <destination>

Where the job is sent upon submission.

Specifies a queue, a server, or a queue at a server. The destination argument can have one of these formats:

<queue name>

Job is submitted to the specified queue at the default server.

@<server name>

Job is submitted to the default queue at the specified server.

<queue name>@<server name>

Job is submitted to the specified queue at the specified server.

Default: Default queue at default server

-r <y|n>

Declares whether the job is rerunnable. Sets job's Rerunable attribute to the argument value. Does not affect how the job is handled in the case where the job was unable to begin execution.

Format: Single character, "*y*" or "*n*"

Table 2-38: Sub-options to r Option

Suboption	Meaning
y	Job is rerunnable.
n	Job is not rerunnable.

Default: "*y*"

Interactive jobs are not rerunnable. Job arrays are always rerunnable. See "qrerun" on page 181.

-R <remove options>

Specifies whether standard output and/or standard error files are automatically removed (deleted) upon job completion.

Sets the job's Remove_Files attribute to *remove options*. Overrides default path names for these streams. Overrides -o and -e options.

This attribute cannot be altered once the job has begun execution.

Default: *Unset*; neither is removed

The *remove options* argument can take the following values:

Table 2-39: discard Argument Values

Option	Meaning
e	The standard error stream is removed (deleted) upon job completion
o	The standard output stream is removed (deleted) upon job completion
eo, oe	Both standard output and standard error streams are removed (deleted) upon job completion
unset	Neither stream is removed.

-S <path list>

Specifies the interpreter or shell path for the job script. Sets job's Shell_Path_List attribute to *path list*.

The *path list* argument is the full path to the interpreter or shell including the executable name.

Only one path may be specified without a hostname. Only one path may be specified per named host. The path selected is the one whose hostname is that of the server on which the job resides.

Format: *<path>[@<hostname>][,<path>@<hostname> ...]*

Default: User's login shell on execution host

Example of using `bash` via a directive:

```
#PBS -S /bin/bash@mars,/usr/bin/bash@jupiter
```

Example of running a Python script from the command line on Linux:

```
qsub -S $PBS_EXEC/bin/pbs_python <script name>
```

Example of running a Python script from the command line on Windows:

```
qsub -S %PBS_EXEC%\bin\pbs_python.exe <script name>
```

-u <user list>

List of usernames. Job is run under a username from this list. Sets job's User_List attribute to *user list*.

Only one username may be specified without a hostname. Only one username may be specified per named host. The server on which the job resides will select first the username whose hostname is the same as the server name. Failing that, the next selection is the username with no specified hostname. The usernames on the server and execution hosts must be the same. The job owner must have authorization to run as the specified user.

Format of *user list: <username>[@<hostname>][,<username>@<hostname> ...]*

Default: Job owner (username on submission host)

-v <variable list>

Specifies environment variables and shell functions to be exported to the job. This is the list of environment variables that are added to those already automatically exported. These variables exist in the user's environment from which `qsub` is run. The job's Variable_List attribute is appended with the variables in *variable list* and their values. See section 2.57.7, "Environment Variables", on page 233.

Format: comma-separated list of strings in the form:

<variable>

or

<variable>=<value>

If a *<variable>=<value>* pair contains any commas, the value must be enclosed in single or double quotes, and the *<variable>=<value>* pair must be enclosed in the kind of quotes not used to enclose the value. For example:

```
qsub -v "var1='A,B,C,D'" job.sh
qsub -v "a=10,var2='A,B',c=20,d='Hello world'" job.sh
```

Default: No environment variables are added to job's variable list.

-V

All environment variables and shell functions in the user's environment where `qsub` is run are exported to the job. The job's Variable_List attribute is appended with all of these environment variables and their values.

-W <additional attributes>

The `-W` option allows specification of some job attributes. Some job attributes must be specified using this option. Those attributes are listed below. Format:

-W <attribute name>=<value>[,<attribute name>=<value>...]

If white space occurs within the *additional attributes* argument, or the equal sign "=" occurs within a *value* string, it must be enclosed with single quotes or double quotes.

The following attributes can be set using the `-W` option only:

block=true

The `qsub` command waits for the job to terminate, then returns the job's exit value. Sets job's block attribute to *True*. When used with X11 forwarding or interactive jobs, no exit value is returned. See section 2.57.8, "Exit Status", on page 234.

create_resv_from_job=<value>

When this job starts, immediately creates and confirms a *job-specific start reservation* on the same resources as the job (including resources inherited by the job), and places the job in the job-specific reservation queue. Sets the job's create_resv_from_job attribute to *True*. Sets the job-specific reservation's reserve_job attribute to the ID of the job from which the reservation was created. The new reservation's duration and start time are the same as the job's walltime and start time. If the job is peer scheduled, the job-specific reservation is created in the pulling complex.

Format: Boolean

Example:

```
qsub -Wcreate_resv_from_job=1 myscript.sh
```

Cannot be used with job arrays or jobs being submitted into a reservation.

depend=<dependency list>

Defines dependencies between this and other jobs. Sets the job's depend attribute to *dependency list*. The *dependency list* has the form:

<type>:<arg list>[,<type>:<arg list> ...]

where except for the *on* type, the *arg list* is one or more PBS job IDs, and has the form:

<job ID>[:<job ID> ...]

The type can be:

after: <arg list>

This job may be scheduled for execution at any point after all jobs in *arg list* have started execution.

afterok: <arg list>

This job may be scheduled for execution only after all jobs in *arg list* have terminated with no errors. See section 2.57.8.1, "Warning About Exit Status with csh", on page 235.

afternotok: <arg list>

This job may be scheduled for execution only after all jobs in *arg list* have terminated with errors. See section 2.57.8.1, "Warning About Exit Status with csh", on page 235.

afterany: <arg list>

This job may be scheduled for execution after all jobs in *arg list* have finished execution, with any exit status (with or without errors.) This job will not run if a job in the *arg list* was deleted without ever having been run.

before: <arg list>

Jobs in *arg list* may begin execution once this job has begun execution.

It is uncommon for users to specify a *before* condition. Rather, PBS adds *before* dependencies automatically to the targets of *after* dependencies.

beforeok: <arg list>

Jobs in *arg list* may begin execution once this job terminates without errors. See section 2.57.8.1, "Warning About Exit Status with csh", on page 235.

beforenotok: <arg list>

If this job terminates execution with errors, jobs in *arg list* may begin. See section 2.57.8.1, "Warning About Exit Status with csh", on page 235.

beforeany: <arg list>

Jobs in *arg list* may begin execution once this job terminates execution, with or without errors.

on: <count>

This job may be scheduled for execution after *count* dependencies on other jobs have been satisfied. This type is used in conjunction with one of the *before* types listed. *count* is an integer greater than 0.

runone:<job ID>

Puts the current job and the job with *job ID* in a set of jobs out of which PBS will eventually run just one. To add a job to a set, specify the job ID of another job already in the set.

Job IDs in the *arg list* of *before* types must have been submitted with a type of *on*.

To use the *before* types, the user must have the authority to alter the jobs in *arg list*. Otherwise, the dependency is rejected and the new job aborted.

Error processing of the existence, state, or condition of the job on which the newly submitted job is performed after the job is queued. If an error is detected, the new job is deleted by the server. Mail is sent to the job submitter stating the error.

Dependency example:

```
qsub -W depend=afterok:123.host1.domain.com /tmp/script
```

In this example, we save the output (the job ID) from the first `qsub` into the shell variable "jobid" so that we can supply it to the *depend* option on the second job:

```
jobid=`qsub first_step.sh`
qsub -W depend=afterok:$jobid second_step.sh
```

group_list=<group list>
: List of group names. Job is run under a group name from this list. Sets job's group_list attribute to *group list*.

  Only one group name may be specified without a hostname. Only one group name may be specified per named host. The server on which the job resides will select first the group name whose hostname is the same as the server name. Failing that, the next selection is the group name with no specified hostname. The group names on the server and execution hosts must be the same. The job submitter's primary group is automatically added to the list.

  Under Windows, the primary group is the first group found for the user by PBS when it queries the accounts database.

  Format of *group list*: *<group name>[@<hostname>][,<group name>@<hostname> ...]*

  Default: Login group name of job owner

pwd

pwd=''

pwd=""
: These forms prompt the user for a password. A space between `W` and `pwd` is optional. Spaces between the quotes are optional. Examples:

```
qsub ...  -Wpwd <return>
qsub ...  -W pwd='' <return>
qsub ...  -W pwd=" " <return>
```

  Available on supported Linux platforms only.

release_nodes_on_stageout=<value>
: When set to *True*, all of the job's vnodes not on the primary execution host are released when stageout begins.

  When cgroups is enabled and this is used with some but not all vnodes from one MoM, resources on those vnodes that are part of a cgroup are not released until the entire cgroup is released.

  The job's stageout attribute must be set for the release_nodes_on_stageout attribute to take effect.

  Format: *Boolean*

  Default: *False*

run_count=<value>
: Sets the number of times the server thinks it has run the job. Sets the value of the job's run_count attribute to *value*.

  Format: Integer greater than or equal to zero

sandbox=<sandbox spec>
: Determines which directory PBS uses for the job's staging and execution. Sets job's sandbox attribute to the value of *sandbox spec*.

  Allowed values for *sandbox spec*:

  PRIVATE
  : PBS creates a job-specific directory for staging and execution.

  HOME or unset
  : PBS uses the user's home directory for staging and execution.

  Format: *String*

stagein=<path list>

stageout=<path list>

Specifies files or directories to be staged in before execution or staged out after execution is complete. Sets the job's stagein and stageout attributes to the specified *path list*s. On completion of the job, all staged-in and staged-out files and directories are removed from the execution host(s). The *path list* has the form:

<file spec>[,<file spec>]

where *<file spec>* is

<execution path>@<hostname>:<storage path>

regardless of the direction of the copy. The name *execution path* is the name of the file or directory on the primary execution host. It can be relative to the staging and execution directory on the execution host, or it can be an absolute path.

The "@" character separates *execution path* from *storage path*.

The *storage path* is the path on *hostname*. The *storage path* can be absolute, or it can be relative to the user's home directory on *hostname*.

If *path list* has more than one *file spec*, i.e. it contains commas, it must be enclosed in double quotes.

If you use a UNC path, the *hostname* is optional. If you use a non-UNC path, the *hostname* is required.

umask=<mask value>

The umask with which the job is started. Sets job's umask attribute to *mask value*. Controls umask of job's standard output and standard error.

The following example allows group and world read of the job's output and error:

```
-W umask=33
```

Format: octal; one to four digits; typically two

Default: *system default*

-X

Allows user to receive X output from interactive job.

DISPLAY variable in submission environment must be set to desired display.

Can be used only with interactive jobs: must be used with one of the following:

```
-I
```

```
-W interactive=true (deprecated)
```

Cannot be used with `-v DISPLAY`.

When used with `-Wblock=true`, no exit status is returned.

Can be used with `-V` option.

Not available under Windows.

-z

Job identifier is not written to standard output.

--version

The `qsub` command returns its PBS version information and exits. This option can only be used alone.

2.57.4 Operands

The `qsub` command accepts as operands one of the following:

(no operands)

Same as with a dash. Any PBS directives and user tasks are read from the command line.

<script>

Path to script. Can be absolute or relative to current directory where qsub is run. The script must be the last argument to qsub.

-

When you use a dash, any PBS directives and user tasks are read from the command line.

-- <executable> [<arguments to executable>]

A single executable (preceded by two dashes) and its arguments

The executable, and any arguments to the executable, are given on the qsub command line. The executable is preceded by two dashes, "--".

All qsub options must come before the "--".

If a script or executable is specified, it must be the last argument to qsub. The arguments to an executable must follow the name of the executable.

When you run qsub this way, it runs the executable directly. It does not start a shell, so no shell initialization scripts are run, and execution paths and other environment variables are not set. You should make sure that environment variables are set correctly.

2.57.5 Standard Output

Job ID for submitted job

If the job is successfully created

(No output)

If the -z option is set

2.57.6 Standard Error

The qsub command writes a diagnostic message to standard error for each error occurrence.

2.57.7 Environment Variables

The qsub command uses the following environment variables:

PBS_DEFAULT

Name of default server.

PBS_DPREFIX

Prefix string which identifies PBS directives.

Environment variables beginning with "*PBS_O_*" are created by qsub. PBS automatically exports the following environment variables to the job, and includes them in the job's Variable_List attribute:

PBS_ENVIRONMENT

Set to *PBS_BATCH* for a batch job. Set to *PBS_INTERACTIVE* for an interactive job.

PBS_JOBDIR

Pathname of job's staging and execution directory on the primary execution host.

PBS_JOBID

Job identifier given by PBS when the job is submitted.

PBS_JOBNAME

Job name specified by submitter.

PBS_NODEFILE
: Name of file containing the list of vnodes assigned to the job when the job runs.

PBS_O_HOME
: User's home directory. Value of HOME taken from user's submission environment.

PBS_O_HOST
: Name of submit host. Value taken from user's submission environment.

PBS_O_LANG
: Value of LANG taken from user's submission environment.

PBS_O_LOGNAME
: User's login name. Value of LOGNAME taken from user's submission environment.

PBS_O_MAIL
: Value of MAIL taken from user's submission environment.

PBS_O_PATH
: User's PATH. Value of PATH taken from user's submission environment.

PBS_O_QUEUE
: Name of the queue to which the job was submitted. Value is taken from job submission, otherwise default queue.

PBS_O_SHELL
: Value of SHELL taken from user's submission environment.

PBS_O_SYSTEM
: Operating system, from `uname -s`, on submit host. Value taken from user's submission environment.

PBS_O_TZ
: Timezone. Value taken from user's submission environment.

PBS_O_WORKDIR
: Absolute path to directory where `qsub` is run. Value taken from user's submission environment.

PBS_QUEUE
: Name of the queue from which the job is executed.

PBS_TMPDIR
: Pathname of scratch directory for PBS components. Set when PBS assigns it.

2.57.8 Exit Status

For non-blocking jobs:

Zero
: Upon successful processing of input

Greater than zero
: Upon failure of `qsub`

For blocking jobs:

Exit value of job
: When job runs successfully

3
: If the job is deleted without being run

2.57.8.1 Warning About Exit Status with `csh`

If a job is run in `csh` and a `.logout` file exists in the user's home directory on the host where the job executes, the exit status of the job is that of the `.logout` script, not the job script. This may impact any inter-job dependencies.

2.58 qterm

Terminates one or both PBS servers, and optionally terminates scheduler(s) and/or MoMs

2.58.1 Synopsis

qterm [-f | -F | -i] [-m] [-s] [-t <type>] [<server name>[<server name> ...]]

qterm --version

2.58.2 Description

The `qterm` command terminates a PBS batch server.

Once the server is terminating, no new jobs are accepted by the server, and no jobs are allowed to begin execution. The impact on running jobs depends on the way the server is shut down.

The `qterm` command does not exit until the server has completed its shutdown procedure.

If the complex is configured for failover, and the primary server is shut down, the normal behavior for the secondary server is to become active. The `qterm` command provides options to manage the behavior of the secondary server; it can be shut down, forced to remain idle, or shut down in place of the primary server.

2.58.2.1 Required Privilege

In order to run the `qterm` command, you must have PBS Operator or Manager privilege.

2.58.3 Options to qterm

(no options)

The `qterm` command defaults to `qterm -t quick`.

-f

If the complex is configured for failover, shuts down both the primary and secondary servers.

Without the `-f` option, `qterm` shuts down the primary server and makes the secondary server active.

The `-f` option cannot be used with the `-i` or `-F` options.

-F

If the complex is configured for failover, shuts down only the secondary server, leaving the primary server active.

The `-F` option cannot be used with the `-f` or `-i` options.

-i

If the complex is configured for failover, leaves the secondary server idle when the primary server is shut down.

The `-i` option cannot be used with the `-f` or `-F` options.

-m

Shuts down the primary server and all MoMs (`pbs_mom`). This option does not cause jobs or subjobs to be killed. Jobs are left running subject to other options to the `qterm` command.

-s

Shuts down the primary server and the scheduler (`pbs_sched`).

-t <type>

immediate
: Shuts down the primary server. Immediately stops all running jobs. Any running jobs that can be checkpointed are checkpointed, terminated, and requeued. Jobs that cannot be checkpointed are terminated and requeued if they are rerunnable, otherwise they are killed.

  If any job cannot be terminated, for example the server cannot contact the MoM of a running job, the server continues to execute and the job is listed as running. The server can be terminated by a second `qterm -t immediate` command.

  While terminating, the server is in the *Terminating* state.

delay
: Shuts down the primary server. The server waits to terminate until all non-checkpointable, non-rerunnable jobs are finished executing. Any running jobs that can be checkpointed are checkpointed, terminated, and requeued. Jobs that cannot be checkpointed are terminated and requeued if they are rerunnable, otherwise they are allowed to continue to run.

  While terminating, the server is in the *Terminating-Delayed* state.

quick
: Shuts down the primary server. Running jobs and subjobs are left running.

  This is the default behavior when no options are given to the `qterm` command.

  While terminating, the server is in the *Terminating* state.

--version
: The `qterm` command returns its PBS version information and exits. This option can only be used alone.

2.58.4 Operands

You optionally specify the list of servers to shut down using *[<server name>[<server name> ...]]*.

If you do not specify any servers, the `qterm` command shuts down the default server.

2.58.4.1 Standard Error

The `qterm` command writes a diagnostic message to standard error for each error occurrence.

2.58.4.2 Exit Status

Zero
: Upon successful processing of all operands presented to the `qterm` command

Greater than zero
: If the `qterm` command fails to process any operand

2.59 tracejob

Extracts and prints log messages for a PBS job

2.59.1 Synopsis

tracejob [-a] [-c <count>] [-f <filter>] [-l] [-m] [-n <days>] [-p <path>] [-s] [-v] [-w <cols>] [-z] <job ID>

tracejob --version

2.59.2 Description

The `tracejob` command extracts log messages for a given *job ID* and prints them in chronological order.

The `tracejob` command extracts information from server, default scheduler, accounting, and MoM logs. Server logs contain information such as when a job was queued or modified. Scheduler logs contain clues as to why a job is not running. Accounting logs contain accounting records for when a job was queued, started, ended, or deleted. MoM logs contain information about what happened to a job while it was running.

To get MoM log messages for a job, `tracejob` must be run on the machine on which the job ran. If the job ran on multiple hosts, you must run `tracejob` on each of those hosts.

Some log messages appear many times. In order to make the output of `tracejob` more readable, messages that appear over a certain number of times (see option `-c` below) are restricted to only the most recent message.

2.59.3 Using tracejob on Job Arrays

If `tracejob` is run on a job array, the information returned is about the job array itself, and not its subjobs. Job arrays do not have associated MoM log messages. If `tracejob` is run on a subjob, the same types of log messages are available as for a job. Certain log messages that occur for a regular job will not occur for a subjob.

2.59.4 Required Privilege

All users have access to server, scheduler, and MoM information. Only Administrator or root can access accounting information.

2.59.5 Options to tracejob

-a

Do not report accounting information.

-c <count>

Set excessive message limit to *count*. If a message is logged at least *count* times, only the most recent message is printed.

The default for *count* is 15.

-f <filter>

Do not include log events of type *filter*. The -f option can be used more than once on the command line. The following table shows each filter with its hex value and category:

Table 2-40: tracejob Filters

Filter	Hex Value	Message Category
error	*0x0001*	Internal errors
system	*0x0002*	System errors
admin	*0x0004*	Administrative events
job	*0x0008*	Job-related events
job_usage	*0x0010*	Job accounting info
security	*0x0020*	Security violations
sched	*0x0040*	Scheduler events
debug	*0x0080*	Common debug messages
debug2	*0x0100*	Uncommon debug messages
resv	*0x0200*	Reservation debug messages
debug3	*0x0400*	Less common than *debug2*
debug4	*0x0800*	Less common than *debug3*

-l

Do not report scheduler information.

-m

Do not report MoM information.

-n <days>

Report information from up to *days* days in the past.

Default number of days: *1* = today

-p <path>

Use *path* as path to PBS_HOME on machine being queried.

-s

Do not report server information.

-w <cols>

Width of current terminal. If *cols* is not specified, tracejob queries OS to get terminal width. If OS doesn't return anything, defaults to *80*.

-v

Verbose. Report more of tracejob's errors than default.

-z

Suppresses printing of duplicate messages.

--version

The tracejob command returns its PBS version information and exits. This option can only be used alone.

2.59.6 Operands

The `tracejob` command accepts one *job ID* operand.

For a job, this has the form:

<sequence number>[.<server name>][@<server name>]

For a job array, the form is:

<sequence number>[][.<server name>][@<server name>]

For a subjob, the form is:

<sequence number>[<index>][.<server name>][@<server name>]

Note that some shells require that you enclose a job array identifier in double quotes.

2.59.7 Exit Status

Zero
: Upon successful processing of all options

Greater than zero
: If `tracejob` is unable to process any options

The PBS Professional Administrator's Guide

2.60 win_postinstall.py

For Windows. Configures PBS MoM or client

2.60.1 Synopsis

<PBS_EXEC>\etc\python win_postinstall.py -u <PBS service account> -p <PBS service account password> -t <installation type> -s <server name> [-c <path to scp command>]

2.60.2 Description

The `win_postinstall.py` command configures the PBS MoM and commands. It performs post-installation steps such as validating the PBS service account username and password, installing the Visual C++ redistributable binary, and creating the `pbs.conf` file in the PBS destination folder.

For an "execution" type of installation, it creates `PBS_HOME`, and registers and starts the PBS_MOM service.

When you use this command during an "execution" type installation of PBS, the command automatically un-registers any old PBS MoM.

Available on Windows only.

2.60.2.1 Required Privilege

You must have Administrator privilege to run this command.

2.60.3 Options to win_postinstall.py

-c, --scp-path <path to scp command>
: Specifies path to `scp` command.

-p, --passwd <PBS service account password>
: Specifies password for PBS service account.

-s, --server <server name>
: Specifies the hostname on which the PBS server will run; required when the installation type is one of "execution" or "client".

-t, --type <installation type>
: Specifies type of installation. Type can be one of "execution" or "client".

-u, --user <PBS service account>
: Specifies PBS service account. When you specify the PBS service account, whether or not you are on a domain machine, include only the username, not the domain. For example, if the full username on a domain machine is *<domain>\<username>*, pass only *<username>* as an argument.

3 MoM Parameters

This chapter describes the configuration files used by MoM and lists the MoM configuration parameters that are found in the Version 1 MoM configuration file, *PBS_HOME/mom_priv/config*. See "About MoMs" on page 37 in the PBS Professional Administrator's Guide.

3.1 Syntax of MoM Configuration File

The Version 1 MoM configuration file contains parameter settings for the MoM on the local host.

Version 1 configuration files list local resources and initialization values for MoM. Local resources are either static, listed by name and value, or externally-provided, listed by name and command path. Local static resources are for use only by the scheduler for MoM's partition. They do not appear in a `pbsnodes -a` query. See the `-c` option to the `pbs_mom` command. Do not change the syntax of the Version 1 configuration file.

Each configuration item is listed on a single line, with its parts separated by white space. Comments begin with a hash-mark ("#").

3.1.1 Windows Notes

If the argument to a MoM option is a pathname containing a space, enclose it in double quotes as in the following:

```
hostn !"\Program Files\PBS\exec\bin\hostn" host
```

When you edit any PBS configuration file, make sure that you put a newline at the end of the file. The Notepad application does not automatically add a newline at the end of a file; you must explicitly add the newline.

3.2 Contents of MoM Configuration File

3.2.1 Replacing Actions

$action <default action> <timeout> <new action>

Replaces the *default action* for an event with the site-specified *new action*. *timeout* is the time allowed for *new action* to run. *new action* is the site-supplied script that replaces *default action*. This is the complete list of values for *default action*:

Table 3-1: How $action is Used

default action	Result
checkpoint	Run *new action* in place of the periodic job checkpoint, after which the job continues to run.
checkpoint_abort	Run *new action* to checkpoint the job, after which the job must be terminated by the script.
multinodebusy <timeout> requeue	Used with cycle harvesting and multi-vnode jobs. Changes default behavior when a vnode becomes busy. Instead of allowing the job to run, the job is requeued. Timeout is ignored. The only *new action* is *requeue*.
restart	Runs *new action* in place of restart.
terminate	Runs *new action* in place of SIGTERM or SIGKILL when MoM terminates a job.

3.2.2 MoM Parameters

$checkpoint_path <path>

MoM passes this parameter to the checkpoint and restart scripts. This path can be absolute or relative to `PBS_HOME/mom_priv`. Overrides default. Overridden by path specified in the `pbs_mom -C` option and by PBS_CHECKPOINT_PATH environment variable. See "Specifying Checkpoint Path" on page 397 in the PBS Professional Administrator's Guide.

$clienthost <hostname>

hostname is added to the list of hosts which are allowed to connect to MoM as long as they are using a privileged port. For example, this allows the hosts "fred" and "wilma" to connect to MoM:

```
$clienthost fred
$clienthost wilma
```

The following hostnames are added to $clienthost automatically: the server, the localhost, and if configured, the secondary server. The server sends each MoM a list of the hosts in the nodes file, and these are added internally to *$clienthost*. None of these hostnames need to be listed in the configuration file.

Two hostnames are always allowed to connect to `pbs_mom`, "`localhost`" and the name returned to MoM by the system call `gethostname()`. These hostnames do not need to be added to the MoM configuration file.

The hosts listed as "clienthosts" make up a "sisterhood" of machines. Any one of the sisterhood will accept connections from within the sisterhood. The sisterhood must all use the same port number.

$cputmult <factor>

This sets a factor used to adjust CPU time used by each job. This allows adjustment of time charged and limits enforced where jobs run on a system with different CPU performance. If MoM's system is faster than the reference system, set factor to a decimal value greater than 1.0. For example:

```
$cputmult 1.5
```

If MoM's system is slower, set factor to a value between *1.0* and *0.0*. For example:

```
$cputmult 0.75
```

$dce_refresh_delta <delta>

Obsolete (2020.1)

Defines the number of seconds between successive refreshings of a job's DCE login context. For example:

```
$dce_refresh_delta 18000
```

$enforce <limit>

MoM will enforce the given *limit*. Some limits have associated values. Syntax:

$enforce <variable name> <value>

$enforce mem

MoM will enforce each job's memory limit.

$enforce cpuaverage

MoM will enforce ncpus when the average CPU usage over a job's lifetime usage is greater than the job's limit.

$enforce average_trialperiod <seconds>

Modifies cpuaverage. Minimum number of seconds of job walltime before enforcement begins.

Format: *Integer*

Default: *120*

$enforce average_percent_over <percentage>

Modifies cpuaverage. Gives percentage by which a job may exceed its ncpus limit.

Format: *Integer*

Default: *50*

$enforce average_cpufactor <factor>

Modifies cpuaverage. The ncpus limit is multiplied by *factor* to produce actual limit.

Format: *Float*

Default: *1.025*

$enforce cpuburst

MoM will enforce the ncpus limit when CPU burst usage exceeds the job's limit.

$enforce delta_percent_over <percentage>

Modifies cpuburst. Gives percentage over limit to be allowed.

Format: *Integer*

Default: *50*

$enforce delta_cpufactor <factor>

Modifies cpuburst. The ncpus limit is multiplied by *factor* to produce actual limit.

Format: *Float*

Default: *1.5*

$enforce delta_weightup <factor>

Modifies cpuburst. Weighting factor for smoothing burst usage when average is increasing.

Format: *Float*

Default: *0.4*

$enforce delta_weightdown <factor>

Modifies cpuburst. Weighting factor for smoothing burst usage when average is decreasing.

Format: *Float*

Default: *0.4*

$ideal_load <load>

Defines the *load* below which the vnode is not considered to be busy. Used with the $max_load directive.

Example:

```
$ideal_load 1.8
```

Format: *Float*

No default

$jobdir_root <stage directory root | PBS_USER_HOME> [shared]

Directory under which PBS creates job-specific staging and execution directories when a job's sandbox attribute is set to *PRIVATE* and this attribute is set to an existing directory. If $jobdir_root is unset, the root directory for the job-specific staging and execution directory defaults to each job owner's home directory. If *stage directory root* does not exist when MoM starts up, MoM will abort. If *stage directory root* does not exist when MoM tries to run a job, MoM will kill the job. Path must be owned by root, and permissions must be *1777*. On Windows, this directory should have *Full Control Permission* for the local Administrators group.

When you set $jobdir_root to a shared (e.g. NFS) directory, tell MoM it is shared by setting the *shared* directive after the directory name:

$jobdir_root <directory name> shared

If the user home directory is shared, tell MoM it is shared:

$jobdir_root PBS_USER_HOME shared

Otherwise sister MoMs can prematurely delete files and directories when nodes are released. This is because when sister nodes are released, those sister MoMs would normally clean up their own files upon release, but this could cause problems in a shared directory. So if $jobdir_root or submitter home directories are shared, you need to tell the sister MoMs not to do the cleanup, and let the primary execution host MoM clean up when the job is finished.

To tell PBS to create job staging and execution directories created under /r/shared, so that each job gets /r/shared/<job-specific directory>, put the following line in MoM's configuration file:

```
$jobdir_root /r/shared
```

To tell PBS to use /scratch when it is a shared directory:

```
$jobdir_root /r/shared shared
```

To tell PBS to use shared submitter home directories:

```
$jobdir_root PBS_USER_HOME shared
```

To tell PBS to use non-shared submitter home directories, leave the $jobdir_root parameter blank.

$job_launch_delay

When the primary MoM gets a job whose tolerate_node_failures attribute is set to *all* or *job_start*, the primary MoM can wait to start the job (running the job script or executable) for up to a configured number of seconds. During this time, execjob_prologue hooks can finish and the primary MoM can check for communication problems with sister MoMs. You configure the number of seconds for the primary MoM to wait for hooks via the job_launch_delay configuration parameter in MoM's config file:

```
$job_launch_delay <number of seconds to wait>
```

Default: the sum of the values of the alarm attributes of any enabled execjob_prologue hooks. If there are no enabled execjob_prologue hooks, the default value is 30 seconds. For example, if there are two enabled execjob_prologue hooks, one with alarm = 30 and one with alarm = 60, the default value of MoM's job_launch_delay is 90 seconds.

After all the execjob_prologue hooks have finished, or MoM has waited for the value of the job_launch_delay parameter, she starts the job.

$kbd_idle <idle wait> <min use> <poll interval>

Declares that the vnode will be used for batch jobs during periods when the keyboard and mouse are not in use.

idle wait

Time, in seconds, that the workstation keyboard and mouse must be idle before being considered available for batch jobs.

Must be set to non-zero value for cycle harvesting to be enabled.

Format: *Integer*

No default

min use

Time, in seconds, during which the workstation keyboard or mouse must continue to be in use before the workstation is determined to be unavailable for batch jobs.

Format: *Integer*

Default: *10*

poll interval

Interval, in seconds, at which MoM checks for keyboard and mouse activity.

Format: *Integer*

Default: *1*

Example:

```
$kbd_idle 1800 10 5
```

$logevent <mask>

Sets the mask that determines which event types are logged by `pbs_mom`. To include all debug events, use *0xffffffff*. See "Log Levels" on page 429 in the PBS Professional Administrator's Guide.

Default: 975

$max_check_poll <seconds>

Maximum time between polling cycles, in seconds. See "Configuring MoM Polling Cycle" on page 38 in the PBS Professional Administrator's Guide. Minimum recommended value: 30 seconds.

Minimum value: *1 second*

Default: *120 seconds*

Format: *Integer*

$max_load <load> [suspend]

Defines the load above which the vnode is considered to be *busy*. Used with the $ideal_load directive. No new jobs are started on a *busy* vnode.

The optional *suspend* directive tells PBS to suspend jobs running on the vnode if the load average exceeds the $max_load number, regardless of the source of the load (PBS and/or logged-in users). Without this directive, PBS will not suspend jobs due to load.

We recommend setting *load* to a value that is slightly higher than the number of CPUs, for example *.25 + ncpus*.

Example:

```
$max_load 3.5
```

Format: *Float*

Default: number of CPUs on machine

$max_poll_downtime <downtime>

When mother superior detects that a sister mom has lost connectivity (e.g. MoM went down or the network is having problems) it waits *downtime* seconds for the sister to reconnect before it gives up and kills the job.

Format: *Integer*

Default: *five minutes*

memreserved <megabytes>

Deprecated. The amount of per-vnode memory reserved for system overhead. This much memory is deducted from the value of resources_available.mem for each vnode managed by this MoM.

For example,

```
memreserved 16
```

Default: *0MB*

$min_check_poll <seconds>

Minimum time between polling cycles, in seconds. Must be greater than zero and less than $max_check_poll. See "Configuring MoM Polling Cycle" on page 38 in the PBS Professional Administrator's Guide. Minimum recommended value: *10 seconds*.

Format: *Integer*

Minimum value: *1 second*

Default: *10 seconds*

$prologalarm <timeout>

Defines the maximum number of seconds the prologue and epilogue may run before timing out.

Example:

```
$prologalarm 30
```

Format: *Integer*

Default: *30 seconds*

$reject_root_scripts { True | False}

When set to *True*, MoM won't acquire any new hook scripts, and MoM won't run job scripts that would execute as root or Admin. However, MoM will run previously-acquired hooks that run as root.

Format: *Boolean*

Default: *False*

$restart_background {True | False}

Controls how MoM runs a restart script after checkpointing a job. When this option is set to *True*, MoM forks a child which runs the restart script. The child returns when all restarts for all the local tasks of the job are done. MoM does not block on the restart. When this option is set to *False*, MoM runs the restart script and waits for the result.

Format: *Boolean*

Default: *False*

$restart_transmogrify {True | False}

Controls how MoM runs a restart script after checkpointing a job.

When this option is set to *True*, MoM runs the restart script, replacing the session ID of the original task's top process with the session ID of the script.

When this option is set to *False*, MoM runs the restart script and waits for the result. The restart script must restore the original session ID for all the processes of each task so that MoM can continue to track the job.

When this option is set to *False* and the restart uses an external command, the configuration parameter restart_background is ignored and treated as if it were set to *True*, preventing MoM from blocking on the restart.

Format: *Boolean*

Default: *False*

$restrict_user {True | False}

Controls whether users not submitting jobs have access to this machine. If value is *True*, restrictions are applied.

See $restrict_user_exceptions and $restrict_user_maxsysid.

Not supported on Windows.

Format: *Boolean*

Default: *False*

$restrict_user_exceptions <user list>

Comma-separated list of users who are exempt from access restrictions applied by $restrict_user. Leading spaces within each entry are allowed. Maximum of 10 names.

$restrict_user_maxsysid <value>

Any user with a numeric user ID less than or equal to *value* is exempt from restrictions applied by $restrict_user.

If $restrict_user is *True* and no *value* exists for $restrict_user_maxsysid, PBS looks in `/etc/login.defs`, if it exists, for the *value*. Otherwise the default is used.

Format: *Integer*

Default: *999*

$restricted <hostname>

The *hostname* is added to the list of hosts which are allowed to connect to MoM without being required to use a privileged port. Queries from the hosts in the restricted list are only allowed access to information internal to this host, such as load average, memory available, etc. They may not run shell commands.

Hostnames can be wildcarded. For example, to allow queries from any host from the domain "xyz.com":

```
$restricted *.xyz.com
```

$sister_join_job_alarm

When the primary MoM gets a job whose tolerate_node_failures attribute is set to *all* or *job_start*, the primary MoM can wait to start the job for up to a configured number of seconds if the sister MoMs do not immediately acknowledge joining the job. This gives the sister MoMs more time to join the job. You configure the number of seconds for the primary MoM to wait for sister MoMs via the sister_join_job_alarm configuration parameter in MoM's config file:

```
$sister_join_job_alarm <number of seconds to wait>
```

Default: the sum of the values of the alarm attributes of any enabled execjob_begin hooks. If there are no enabled execjob_begin hooks, the default value is 30 seconds. For example, if there are two enabled execjob_begin hooks, one with alarm = 30 and one with alarm = 20, the default value of MoM's sister_join_job_alarm is 50 seconds.

After all the sister MoMs have joined the job, or MoM has waited for the value of the $sister_join_job_alarm parameter, she starts the job.

$suspendsig <suspend signal> [resume signal]

Alternate signal *suspend signal* is used to suspend jobs instead of SIGSTOP. Optional *resume signal* is used to resume jobs instead of SIGCONT.

$tmpdir <directory>

Location where each job's scratch directory will be created.

PBS creates a temporary directory for use by the job, not by PBS. PBS creates the directory before the job is run and removes the directory and its contents when the job is finished. It is scratch space for use by the job. Permission must be 1777 on Linux, writable by *Everyone* on Windows.

Example:

```
$tmpdir /memfs
```

Default on Linux: `/var/tmp`

Default on Windows: value of the TMP environment variable

$usecp <hostname:source directory> <destination directory>

MoM uses `/bin/cp` to deliver output files when the destination is a network mounted file system, or when the source and destination are both on the local host, or when the *source directory* can be replaced with the *destination directory* on *hostname*. Both *source directory* and *destination directory* are absolute pathnames of directories, not files.

Overrides PBS_RCP and PBS_SCP.

Use trailing slashes on both the source and destination. For example:

```
$usecp HostA:/users/work/myproj/ /sharedwork/proj_results/
```

$wallmult <factor>

Each job's walltime usage is multiplied by *factor*. For example:

```
$wallmult 1.5
```

4
Scheduler Parameters

This chapter lists scheduler configuration parameters. These parameters are found in each scheduler's configuration file, *PBS_HOME/sched_priv/sched_config*.

4.1 Format of Scheduler Configuration File

4.1.1 Parameters with Separate Primetime and Non-primetime Specification

If a scheduler parameter can be specified separately for primetime and non-primetime, the format for the parameter is the following:

name: value [prime | non_prime | all | none]

- The *name* field cannot contain any whitespace.
- The *value* field may contain whitespace if the string is double-quoted. *value* can be: *True* | *False* | <number> | <string>. "*True*" and "*False*" are not case-sensitive.
- The third field allows you to specify that the setting is to apply during primetime, non-primetime, all the time, or none of the time. A blank third field is equivalent to "*all*" which means that it applies to both primetime and non-primetime.

  Acceptable values: "*all*", "*ALL*", "*none*", "*NONE*", "*prime*", "*PRIME*", "*non_prime*", "*NON_PRIME*"

4.1.2 Parameters without Separate Primetime and Non-primetime Specification

If a scheduler parameter cannot be specified separately for primetime and non-primetime, the format for the parameter is the same as the above, except that there is no third field.

4.1.3 Format Details

- Each entry must be a single, unbroken line.
- Entries must be quoted if they contain whitespace.
- Any line starting with a "#" is a comment, and is ignored.

4.2 Configuration Parameters

backfill

Deprecated. Use the backfill_depth queue/server attribute instead. Toggle that controls whether PBS uses backfilling. If this is set to *True*, this scheduler attempts to schedule smaller jobs around higher-priority jobs when using strict_ordering, as long as running the smaller jobs won't change the start time of the jobs they were scheduled around. This scheduler chooses jobs in the standard order, so other high-priority jobs will be considered first in the set to fit around the highest-priority job.

Format: *Boolean*

Default: *True all*

backfill_prime

This scheduler will not run jobs which would overlap the boundary between primetime and non-primetime. This assures that jobs restricted to running in either primetime or non-primetime can start as soon as the time boundary happens.

See also prime_spill, prime_exempt_anytime_queues.

Format: *Boolean*

Default: *False all*

by_queue

If set to *True*, all jobs that can be run from the highest-priority queue are run, then any jobs that can be run from the next queue are run, and so on. Queues are ordered highest-priority first. If by_queue is set to *False*, all jobs are treated as if they are in one large queue. The by_queue parameter is overridden by the round_robin parameter when round_robin is set to *True*.

See "Examining Jobs Queue by Queue" on page 112 in the PBS Professional Administrator's Guide.

Format: *Boolean*

Default: *True all*

dedicated_prefix

Queue names with this prefix are treated as dedicated queues, meaning jobs in that queue are considered for execution only when the system is in dedicated time as specified in the configuration file `PBS_HOME/sched_priv/dedicated_time`.

See "Dedicated Time" on page 127 in the PBS Professional Administrator's Guide.

Format: *String*

Default: *ded*

fair_share

Enables the fairshare algorithm, and turns on usage collecting. Jobs will be selected based on a function of their recent usage and priority (shares). Not a prime option.

See "Using Fairshare" on page 138 in the PBS Professional Administrator's Guide.

Format: *Boolean*

Default: *False all*

fairshare_decay_factor

Decay multiplier for fairshare usage reduction. Each decay period, the usage is multiplied by this value. Valid values: between 0 and 1, not inclusive. Not a prime option.

Format: *Float*

Default: 0.5

fairshare_decay_time

Time between fairshare usage decay operations. Not a prime option.

Format: *Duration*

Default: *24:00:00*

fairshare_entity

Specifies the entity for which fairshare usage data will be collected. Can be one of "*euser*", "*egroup*", "*Account_Name*", "*queue*", or "*egroup:euser*". Not a prime option.

Format: *String*

Default: *euser*

fairshare_enforce_no_shares

If this option is set to *True*, jobs whose entity has zero shares will never run. When *False*, jobs whose entity has zero shares can run jobs only when no other entities have jobs that are available to run. Requires fair_share parameter to be enabled. Not a prime option.

Format: *Boolean*

Default: *True*

fairshare_usage_res

Specifies the mathematical formula to use in fairshare calculations. Is composed of PBS resources as well as mathematical operators that are standard Python operators and/or those in the Python math module. When using a PBS resource, if resources_used.<resource name> exists, that value is used. Otherwise, the value is taken from Resource_List.<resource name>. Not a prime option.

See "Tracking Resource Usage" on page 142 in the PBS Professional Administrator's Guide.

Format: *String*

Default: *"cput"*

half_life

Deprecated (as of 13.0).

The half-life for fairshare usage; after the amount of time specified, the fairshare usage is halved. Requires that fair_share parameter be enabled. Not a prime option.

See "Using Fairshare" on page 138 in the PBS Professional Administrator's Guide.

Format: *Duration*

Default: *24:00:00*

job_sort_key

Specifies how jobs should be sorted. job_sort_key can be used to sort using either (a) resources or (b) special case sorting routines. Multiple job_sort_key entries can be used, one to a line, in which case the first entry will be the primary sort key, the second will be used to sort equivalent items from the first sort, etc. This attribute is overridden by the job_sort_formula attribute. If both are set, job_sort_key is ignored and an error message is printed.

Syntax:

job_sort_key: "<resource name> HIGH|LOW"

job_sort_key: "fairshare_perc HIGH|LOW"

job_sort_key: "job_priority HIGH|LOW"

Options: One of the following is required.

HIGH
Specifies descending sort.

LOW
Specifies ascending sort.

There are three special case sorting routines, which can be used instead of *resource name*:

Table 4-1: Special Sorting in job_sort_key

Special Sort	Description
fairshare_perc HIGH	Sort based on how much fairshare percentage the entity deserves, based on the values in the `resource_group` file. If user A has more priority than user B, all of user A's jobs will always be run first. Past history is not used. For calculation, see "Computing Target Usage for Each Vertex (fairshare_perc)" on page 144 in the PBS Professional Administrator's Guide. This should only be used if entity share (strict priority) sorting is needed. See "Sorting Jobs by Entity Shares (Was Strict Priority)" on page 132 in the PBS Professional Administrator's Guide Incompatible with fair_share scheduling parameter being *True*.
job_priority HIGH|LOW	Sort jobs by the job priority attribute regardless of job owner.
sort_priority HIGH|LOW	**Deprecated**. See job_priority above.

The following example illustrates how to sort jobs so that those with high CPU count come first:

```
job_sort_key: "ncpus HIGH" all
```

The following example shows how to sort jobs so that those with lower memory come first:

```
job_sort_key: "mem LOW" prime
```

Format: *Quoted string*

Default: Not enforced

load_balancing

Removed (2022.1).

load_balancing_rr

Removed.

log_filter

Obsolete. See "log_events" on page 298 of the PBS Professional Reference Guide.

mom_resources

Removed as of 2022.1.0.

node_sort_key

Defines sorting on resource or priority values on vnodes. Resource must be numerical, for example, *long* or *float*. Up to 20 node_sort_key entries can be used, in which case the first entry will be the primary sort key, the second will be used to sort equivalent items from the first sort, etc.

Syntax:

node_sort_key: <resource name> | sort_priority <HIGH | LOW>

node_sort_key: <resource name> <HIGH | LOW> <total | assigned | unused>

where

total
Use the resources_available value. This is the default setting when sorting on a resource.

assigned
Use the resources_assigned value.

unused
Use the value given by resources_available - resources_assigned.

sort_priority
Sort vnodes by the value of the vnode priority attribute.

When sorting on a resource, the default third field is "*total*".

See "Sorting Vnodes on a Key" on page 223 in the PBS Professional Administrator's Guide.

Format: *String*

Default: *node_sort_key: "sort_priority HIGH all"*

nonprimetime_prefix

Queue names which start with this prefix are treated as non-primetime queues. Jobs in these queues run only during non-primetime. Primetime and non-primetime are defined in the `holidays` file.

See "Using Primetime and Holidays" on page 189 in the PBS Professional Administrator's Guide.

Format: *String*

Default: *np_*

peer_queue

Defines the mapping of a pulling queue to a furnishing queue for peer scheduling. Maximum number is 50 peer queues per scheduler.

See "Peer Scheduling" on page 163 in the PBS Professional Administrator's Guide.

Format: *String*

Default: Unset

preemptive_sched

Enables job preemption.

See preempt_order and "Using Preemption" on page 179 in the PBS Professional Administrator's Guide for details.

Format: *String*

Default: *True all*

preempt_order

No longer available. Use the preempt_sort scheduler attribute. See "preempt_order" on page 299..

preempt_prio

No longer available. Use the preempt_sort scheduler attribute. See "preempt_prio" on page 300..

preempt_queue_prio

No longer available. Use the preempt_sort scheduler attribute. See "preempt_queue_prio" on page 300..

preempt_sort

No longer available. Use the preempt_sort scheduler attribute. See "preempt_sort" on page 300..

primetime_prefix

Queue names starting with this prefix are treated as primetime queues. Jobs in these queues run only during primetime. Primetime and non-primetime are defined in the `holidays` file.

See "Using Primetime and Holidays" on page 189 in the PBS Professional Administrator's Guide.

Format: *String*

Default: *p_*

prime_exempt_anytime_queues

Determines whether *anytime* queues are controlled by backfill_prime.

If set to *True*, jobs in an *anytime* queue are not prevented from running across a primetime/non-primetime or non-primetime/primetime boundary.

If set to *False*, the jobs in an *anytime* queue may not cross this boundary, except for the amount specified by their prime_spill setting.

See also backfill_prime, prime_spill.

Format: *Boolean*

Default: *False*

prime_spill

Specifies the amount of time a job can spill over from non-primetime into primetime or from primetime into non-primetime. This option can be separately specified for primetime and non-primetime. This option is only meaningful if backfill_prime is *True*.

See also backfill_prime, prime_exempt_anytime_queues.

For example, non-primetime jobs can spill into primetime by 1 hour:

```
prime_spill: 1:00:00 prime
```

For example, jobs in either prime/non-prime can spill into the other by 1 hour:

```
prime_spill: 1:00:00 all
```

Format: *Duration*

Default: *00:00:00*

provision_policy

Specifies how vnodes are selected for provisioning. Can be set by Manager only; readable by all. Can be set to one of the following:

avoid_provision

PBS first tries to satisfy the job's request from free vnodes that already have the requested AOE instantiated. PBS uses node_sort_key to sort these vnodes.

If PBS cannot satisfy the job's request using vnodes that already have the requested AOE instantiated, PBS uses the server's node_sort_key to select the free vnodes that must be provisioned in order to run the job, choosing from any free vnodes, regardless of which AOE is instantiated on them.

Of the selected vnodes, PBS provisions any that do not have the requested AOE instantiated on them.

aggressive_provision

PBS selects vnodes to be provisioned without considering which AOE is currently instantiated.

PBS uses the server's node_sort_key to select the vnodes on which to run the job, choosing from any free vnodes, regardless of which AOE is instantiated on them. Of the selected vnodes, PBS provisions any that do not have the requested AOE instantiated on them.

Format: *String*

Default: *aggressive_provision*

resources

Specifies those resources which are not to be over-allocated, or if Boolean are to be honored, when scheduling jobs. Vnode-level Boolean resources are automatically honored and do not need to be listed here. Limits are set by setting resources_available.<resource name> on vnodes, queues, and the server. A scheduler considers numeric (integer or float) items as consumable resources and ensures that no more are assigned than are available (e.g. ncpus or mem). Any string resources are compared using string comparisons. If "host" is not added to the resources line, when the user submits a job requesting a specific vnode in the following syntax:

```
qsub -l select=host=vnodeName
```

the job will run on any host.

Format: *String*

Default: *ncpus, mem, arch, host, vnode*, *aoe*

resource_unset_infinite

Resources in this list are treated as infinite if they are unset. Cannot be set differently for primetime and non-primetime.

Example:

```
resource_unset_infinite: "vmem, foo_licenses"
```

Format: *Comma-delimited list of resources*

Default: Empty list

round_robin

If set to *True*, this scheduler considers one job from the first queue, then one job from the second queue, and so on in a circular fashion. The queues are ordered with the highest-priority queue first. Each scheduling cycle starts with the same highest-priority queue, which will therefore get preferential treatment.

If there are groups of queues with the same priority, and this parameter is set to *True*, this scheduler round-robins through each group of queues before moving to the next group.

If round_robin is set to *False*, this scheduler considers jobs according to the setting of the by_queue parameter.

When *True*, overrides the by_queue parameter.

Format: *Boolean*

Default: *False all*

server_dyn_res

Directs this scheduler to replace the server's resources_available values with new values returned by a site-specific external script or program.

See "Creating Server Dynamic Resource Scripts" on page 263 in the PBS Professional Administrator's Guide for details of how to use this parameter.

Default timeout for server dynamic resource scripts is 30 seconds. You can configure this in the scheduler server_dyn_res_alarm attribute.

Format: *String*

Default: Unset

smp_cluster_dist

Deprecated (12.2). Specifies how single-host jobs should be distributed to all hosts of the complex.

Options:

pack

Keep putting jobs onto one host until it is full and then move on to the next.

round_robin
Put one job on each vnode in turn before cycling back to the first one.

See "SMP Cluster Distribution" on page 216 in the PBS Professional Administrator's Guide and "Using Load Balancing" on page 158 in the PBS Professional Administrator's Guide.

Format: *String*

Default: *pack all*

strict_fifo

Deprecated. Use strict_ordering.

strict_ordering

Specifies that jobs must be run in the order determined by whatever sorting parameters are being used. This means that a job cannot be skipped due to resources required not being available. If a job due to run next cannot run, no job will run, unless backfilling is used, in which case jobs can be backfilled around the job that is due to run next.

See "FIFO with Strict Ordering" on page 150 in the PBS Professional Administrator's Guide.

Example line in `PBS_HOME/sched_priv/sched_config`:

```
strict_ordering: True ALL
```

Format: *Boolean*

Default: *False all*

unknown_shares

The number of shares for the *unknown* group. These shares determine the portion of a resource to be allotted to that group via fairshare. Requires fair_share to be enabled.

See "Using Fairshare" on page 138 in the PBS Professional Administrator's Guide.

Format: *Integer*

Default: The unknown group gets 0 shares

5 List of Built-in Resources

This chapter lists all of the built-in PBS resources. For information on setting, viewing, and using resources, see "Using PBS Resources" on page 227 in the PBS Professional Administrator's Guide.

5.1 Resource Data Types

Data types for resources are described in section 7.2, "Resource Formats", on page 359.

Boolean

Name of Boolean resource is a string.

Values:

TRUE, True, true, T, t, Y, y, 1

FALSE, False, false, F, f, N, n, 0

Duration

A period of time, expressed either as

An integer whose units are seconds

or

[[hours:]minutes:]seconds[.milliseconds]

in the form:

[[[HH]HH:]MM:]SS[.milliseconds]

Milliseconds are rounded to the nearest second.

Float

Floating point. Allowable values: [+-] 0-9 [[0-9] ...][.][[0-9] ...]

Long

Long integer. Allowable values: 0-9 [[0-9] ...], and + and -

<queue name>@<server name>

Size

Number of bytes or words. The size of a word is 64 bits.

Format: *<integer>[<suffix>]*

where *suffix* can be one of the following:

Table 5-1: Size in Bytes

Suffix	Meaning	Size
b or w	Bytes or words	1
kb or kw	Kilobytes or kilowords	2 to the 10th, or 1024
mb or mw	Megabytes or megawords	2 to the 20th, or 1,048,576
gb or gw	Gigabytes or gigawords	2 to the 30th, or 1,073,741,824
tb or tw	Terabytes or terawords	2 to the 40th, or 1024 gigabytes
pb or pw	Petabytes or petawords	2 to the 50th, or 1,048,576 gigabytes

Default: *bytes*

Note that a scheduler rounds all resources of type size up to the nearest kb.

String

Any character, including the space character.

Only one of the two types of quote characters, " or ', may appear in any given value.

Values:[_a-zA-Z0-9][[-_a-zA-Z0-9 ! " # $ % ´ ( ) * + , - . / : ; < = > ? @ [\ ] ^ _ ' { | } ~] ...]

String resource values are case-sensitive. No limit on length.

String Array

Comma-separated list of strings.

Strings in string_array may not contain commas. No limit on length.

Python type is *str*.

A string array resource with one value works exactly like a string resource.

5.2 Viewing Resource Information

You can see attribute values of resources for the server, queues, and vnodes using the `qmgr` or `pbsnodes` commands. The value in the server, queue, or vnode resources_assigned attribute is the amount explicitly requested by running and exiting jobs and, at the server and vnodes, started reservations.

You can see job attribute values using the `qstat` command. The value in the job's Resource_List attribute is the amount explicitly requested by the job. See "Resources Requested by Job" on page 241 in the PBS Professional Administrator's Guide.

The following table summarizes how to find resource information:

Table 5-2: How to View Resource Information

Location	Item to View	Command
server	default_chunk, default_qsub_arguments, resources_available, resources_assigned, resources_default	qmgr, qstat, pbsnodes
scheduler	`sched_config file`	Favorite editor or viewer
queues	default_chunk, resources_available, resources_assigned, resources_default	qmgr, qstat
MoM and vnodes	resources_available, sharing, pcpus, resources_assigned	qmgr, pbsnodes
	`mom_config file`	Favorite editor or viewer
job	Resource_List	qstat
reservation	Resource_List	pbs_rstat -f
accounting	`resources_assigned` entry in accounting log	Favorite editor or viewer

Every consumable resource, for example mem, can appear in four PBS attributes. These attributes are used in the following elements of PBS:

Table 5-3: Values Associated with Consumable Resources

Attribute	Vnode	Queue	Server	Accounting Log	Job	Scheduler
resources_available	Yes	Yes	Yes			Yes
resources_assigned	Yes	Yes	Yes	Yes		
resources_used				Yes	Yes	Yes
Resource_List					Yes	Yes

5.3 Resource Flags

Resource flags are described and listed in "Specifying Resource Level and Consumability" on page 255 in the PBS Professional Administrator's Guide.

5.4 Attributes where Resources Are Tracked

Resources are tracked in the following attributes:

Table 5-4: Attributes Where Resources Are Tracked

Resource Being Tracked	Attribute Name			
	Server and Queue	Vnode	Job	Reservation
Amount of each resource available for use at the object (server, queue, vnode)	resources_available.<resource name>	resources_available.<resource name>		
Amount of each resource allocated to jobs running and exiting at the object (server, queue, vnode)	resources_assigned.<resource name>	resources_assigned.<resource name>		
Amount of each resource used by the job			resources_used.<resource name>	
Amount of each job-wide resource that is assigned to any job that does not explicitly request the resource	resources_default.<resource name>			
Amount of each host-level resource that is assigned to each chunk of any job where that does not explicitly request the resource	default_chunk.<resource name>			

Table 5-4: Attributes Where Resources Are Tracked

Resource Being Tracked	Attribute Name			
	Server and Queue	Vnode	Job	Reservation
List of resources requested by the object (job or reservation)			Resource_List.<resource name>	Resource_List.<resource name>
List of chunks for the job. Each chunk shows the name of the vnode from which it is taken along with the host-level, consumable resources allocated from that vnode.			exec_vnode	
List of vnodes and resources allocated to them to satisfy the chunks requested for this reservation or occurrence				resv_nodes

5.5 Resource Table Format

In the following tables, the columns contain the following information:

Name
: The name of the resource

Description
: A description of the resource's function

Format
: The resource's format

Scope

Some resources are either:

- Job-wide and can be requested only outside of a select statement
- Host-level and can be requested only inside of a select statement

Consumable

A resource is consumable if use of this resource by a job reduces the amount available to other jobs

Val/Opt

If the resource can take only specific values or options, each is listed here

Value/Option Description

If the resource can take only specific values or options, the behavior of each value or option is described here

Default Value

The resource's default value, if any

Python Type

The resource's Python type

Platform

Platform where available

5.6 Resources Built Into PBS

Resources								
Name Description	Format	Scope	Consumable	Val / Opt	Value/Option Description	Default Value	Python Type	Platform
aoe List of AOEs (Application Operating Environments) that can be instantiated on this vnode. Case-sensitive. An AOE is the environment that results from provisioning a vnode. Each job can request at most one AOE. Cannot be set on server's host.	*string array*	Host-level	No	Allowable values are site-dependent.		No default	str	

Resources								
Name Description	Format	Scope	Consumable	Val / Opt	Value/Option Description	Default Value	Python Type	Platform
arch System architecture. One architecture can be defined for a vnode. One architecture can be requested per vnode. Allowable values and effect on job placement are site-dependent. The resources_available.arch resource is the value reported by MoM unless explicitly set by the administrator.	*String*	Host-level	No	*linux*	Linux	No default	str	Linux
				linux_cpuset	Linux with cpusets			Linux with cpusets
				XT	CLE			CLE
				windows	Windows			Windows
cput Amount of CPU time used by the job for all processes on all vnodes. Establishes a job-wide resource limit.	*Duration*	Job-wide	No			No default	pbs.duration	
energy The energy used by a job. Set by PBS.	*Float.* Units: *kWh*		Yes			No default		
eoe Stands for "Energy Operational Environment". When set on a vnode in resources_available.eoe, contains the list of available power profiles. When set for a job in Resource_List.eoe, can contain at most one power profile. (A job can request only one power profile.) Automatically added to `resources:` line in `sched_config`.	*string array*		No			For resources_available.eoe: *unset* For Resource_List.eoe: no default	str	
exec_vnode The vnodes that PBS estimates this job will use. This is not the job's exec_vnode attribute. This appears only in job's estimated attribute. Cannot be requested for a job; used for reporting only. Read-only.	*String*					No default	str	

Resources								
Name Description	Format	Scope	Consumable	Val / Opt	Value/Option Description	Default Value	Python Type	Platform
file Size of any single file that may be created by the job. A scheduler rounds all resources of type size up to the nearest kb.	*Size*	Job-wide				No default	pbs.size	
hbmem High-bandwidth memory. Available only on some architectures such as Xeon Phi (**deprecated**) KNL.	*Size*	Host-level	Yes		Values must be greater than or equal to zero.	No default	pbs.size	Xeon Phi KNL
host Name of execution host. Site-dependent.	*String*	Host-level				Automatically set to the short form of the hostname in the Mom attribute.	str	
max_walltime Maximum walltime allowed for a shrink-to-fit job. Job's actual walltime is between max_walltime and min_walltime. PBS sets walltime for a shrink-to-fit job. If max_walltime is specified, min_walltime must also be specified. Cannot be used for resources_min or resources_max. Cannot be set on job arrays or reservations.	*Duration*	Job-wide	No	Must be greater than or equal to min_walltime.		*5 years*	pbs.duration	
mem Amount of physical memory i.e. workingset allocated to the job, either job-wide or host-level. A scheduler rounds all resources of type size up to the nearest kb.	*Size*	Either job-wide or host-level. Can be requested only inside of a select statement.	Yes			No default	pbs.size	

Resources								
Name Description	Format	Scope	Consumable	Val / Opt	Value/Option Description	Default Value	Python Type	Platform
min_walltime Minimum walltime allowed for a shrink-to-fit job. When min_walltime is specified, job is a shrink-to-fit job. If this attribute is set, PBS sets the job's walltime. Job's actual walltime is between max_walltime and min_walltime. Cannot be used for resources_min or resources_max. Cannot be set on job arrays or reservations.	*Duration*	Job-wide	No	Must be less than or equal to max_walltime.		No default	pbs.duration	
mpiprocs Number of MPI processes for this chunk. Cannot use sum from chunks as job-wide limit. The number of lines in `PBS_NODEFILE` is the sum of the values of mpiprocs for all chunks requested by the job. For each chunk with mpiprocs=P, the host name for that chunk is written to the `PBS_NODEFILE` *P* times.	*Integer*	Host-level				If ncpus >0: *1* Otherwise: *0*	int	

Resources								
Name Description	Format	Scope	Consumable	Val / Opt	Value/Option Description	Default Value	Python Type	Platform
nchunk Number of chunks requested between plus symbols in a select statement. For example, if the select statement is `-lselect 4:ncpus=2+12:ncpus=8`, the value of nchunk for the first part is *4*, and for the second part it is *12*. The nchunk resource cannot be named in a select statement; it can only be specified by placing a number before the colon, as in the above example. When the number is omitted, nchunk is 1. This resource can be used to specify the default number of chunks at the server or queue. Example: `set queue myqueue default_chunk.nchunk=2` This resource cannot be used in server and queue resources_min and resources_max.	*Integer*		No			*1*	int	
ncpus Number of processors.	*Integer*	Host-level	Yes			No default	int	
nice Nice value with which the job is to be run. Host-dependent.	*Integer*	Job-wide				No default	int	
nodect **Deprecated**. Number of chunks in resource request from selection directive, or number of hosts requested from node specification. Read-only.	*Integer*	Job-wide				*1*	int	
nodes **Deprecated**. Number of hosts requested.	*Integer*					No default		

Resources								
Name Description	Format	Scope	Consumable	Val / Opt	Value/Option Description	Default Value	Python Type	Platform
ompthreads Number of OpenMP threads for this chunk. Cannot use sum from chunks as job-wide limit. For the MPI process with rank 0, the environment variables NCPUS and OMP_NUM_THREADS are set to the value of ompthreads. For other MPI processes, behavior is dependent on MPI implementation.	*Integer*	Host-level	No			Value of ncpus	int	
pcput Amount of CPU time allocated to any single process in the job. Establishes a per-process resource limit.	*Duration*	Job-wide	No			No default	pbs.duration	
pmem Amount of physical memory (workingset) for use by any single process of the job. Establishes a per-process resource limit. A scheduler rounds all resources of type size up to the nearest kb.	*Size*	Job-wide	No			No default	pbs.size	

Resources								
Name Description	Format	Scope	Consumable	Val / Opt	Value/Option Description	Default Value	Python Type	Platform
preempt_targets List of resources and/or queues. Jobs requesting those resources or in those queues are preemption targets.	*string array* Syntax: *preempt_targets="Queue=<queue name>[,Queue=<queue name>],Resource_List.<resource>=<value>[,Resource_List.<resource>= <value>]"* or *preempt_targets=None* Keywords "queue" and "none" are case-insensitive. You can list multiple comma-separated targets.	Job-wide	No			No default	str	
pvmem Amount of virtual memory for use by any single process in the job. Establishes a per-process resource limit. A scheduler rounds all resources of type size up to the nearest kb.	*Size*	Job-wide	No			No default	pbs.size	
site Arbitrary string resource.	*String*	Job-wide	No			No default	str	
software Site-specific software specification.	*String*	Job-wide		Allowable values and effect on job placement are site-dependent.		No default	pbs.software	

Resources								
Name Description	Format	Scope	Consumable	Val / Opt	Value/Option Description	Default Value	Python Type	Platform
soft_walltime Soft limit on walltime. Similar to walltime, but cannot be requested by unprivileged users, and job is not killed if it exceeds its soft_walltime. A job's soft_walltime cannot exceed its walltime. Can be set by Manager only.	*Duration*					No default	pbs.duration	
start_time The estimated start time for this job. Cannot be requested for a job; used for reporting only. Appears only in job's estimated attribute. Read-only.	*Integer*					No default	int	
vmem Amount of virtual memory for use by all concurrent processes in the job. Establishes a per-chunk resource limit. A scheduler rounds all resources of type size up to the nearest kb.	*Size*	Host-level	Yes			No default	pbs.size	
vnode Name of virtual node (vnode) on which to execute. Site-dependent. See "Vnode Attributes" on page 320 of the PBS Professional Reference Guide.	*String*	Host-level				No default	str	
vntype The type of the vnode.	*string array*	Host-level	No			No default	str	all
walltime Amount of wall-clock time. Establishes a job-wide resource limit. Actual elapsed time may differ from walltime during Daylight Savings transitions.	*Duration*	Job-wide	No			5 years	pbs.duration	

6 Attributes

This chapter lists all of the supported PBS attributes. Attributes are listed by the PBS object they modify. For example, all supported attributes of jobs are listed in section 6.11, “Job Attributes”, on page 327. Attributes are case-sensitive.

6.1 Attribute Behavior

- When you set the value of most attributes, the change takes place immediately. You do not need to restart any daemons in order to make the change.
- When an attribute is unset, it behaves as if it is at its default value.

6.2 How To Set Attributes

You set most attributes via the qmgr command. You can set vnode attributes during vnode creation (see "Creating Vnodes" on page 42 in the PBS Professional Administrator’s Guide), or afterward (see "Configuring Vnodes" on page 45 in the PBS Professional Administrator’s Guide). Many job attributes can be set at submission via the qsub command.

The following are the instructions for setting most attributes.

To set the value of a non-string_array attribute, use the `qmgr` command, either from the command line or within `qmgr`:

```
qmgr -c "set <object> <attribute> = <value>"
Qmgr: set <object> <attribute> = <value>
```

To set or change the value of a string_array attribute, use the qmgr command, either from the command line or within qmgr:

```
qmgr -c "set <object> <attribute> = <value>"
qmgr -c 'set <object> <attribute> = "<value,value>"'
qmgr -c 'set <object> <attribute> += <value>'
qmgr -c 'set <object> <attribute> -= <value>'
Qmgr: set <object> <attribute> = <value>
Qmgr: set <object> <attribute> = '<value,value>'
Qmgr: set <object> <attribute> += <value>
Qmgr: set <object> <attribute> -= <value>
```

To unset the value of an attribute:

```
qmgr -c "unset <object> <attribute>"
Qmgr: unset <object> <attribute>
```

where <*object*> is one of *server*, *queue*, *hook*, *node*, or *sched*.

For example, to set resources_max.walltime at the server to be 24 hours:

```
Qmgr: set server resources_max.walltime = 24:00:00
```

See "qmgr" on page 152.

6.3 Viewing Attribute Values

If you want to view attribute values, the following commands are helpful:

qstat; see section 2.55, "qstat", on page 200

qmgr; see section 2.45, "qmgr", on page 152

pbs_rstat; see section 2.30, “pbs_rstat”, on page 94

- To see server attributes, use one of the following:
  ```
  qstat -B -f
  Qmgr: list server
  ```
- To see queue attributes, use one of the following:
  ```
  qstat -Q -f <queue name>
  Qmgr: list queue <queue name>
  ```
- To see job attributes:
  ```
  qstat -f <job ID>
  ```
- To see hook attributes:
  ```
  Qmgr: list hook <hook name>
  ```
- To see scheduler attributes:
  ```
  Qmgr: list sched
  ```
- To see vnode attributes:
  ```
  Qmgr: list node <node name>
  ```
- To see reservation attributes:
  ```
  pbs_rstat -F
  ```

6.4 Attribute Table Format

In the following tables, the columns contain the following information:

Name
: The name of the attribute

Description
: A description of the attribute's function

Format
: The attribute's format

Val/Opt
: If the attribute can take only specific values or options, each is listed here

Value/Option Description

If the attribute can take only specific values or options, the behavior of each value or option is described here

Default Value, Def Val

The attribute's default value, if any

Python Type

The attribute's Python type

User, Oper, Mgr

Indicates the actions allowed for unprivileged users, Operators, and Managers

The following table shows the operations allowed and their symbols:

Table 6-1: User, Operator, Manager Actions

Symbol	Explanation
r	Entity can read attribute
w	Entity can directly set or alter attribute
s	Entity can set but not alter attribute
a	Entity can alter but not set attribute
i	Entity can indirectly set attribute
-	Entity cannot set or alter attribute, whether directly or indirectly

6.5 Caveats

- The Python types listed as Python dictionaries support a restricted set of operations. They can reference values by index. Other features, such as has_key(), are not available.
- Do not use `qmgr` to set attributes for reservation queues.

6.6 Server Attributes

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
acl_host_enable Specifies whether the server obeys the host access control list in the acl_hosts server attribute.	*Boolean.*		When this attribute is *True*, the server limits host access according to the access control list.	*False*; all hosts allowed access	bool	r	r	r, w
acl_host_moms_enable Specifies whether all MoMs are automatically allowed to contact the server with the same privilege as hosts listed in the acl_hosts server attribute.	*Boolean*	*True*	All MoMs are automatically allowed to contact the server with the same privilege as hosts listed in the acl_hosts server attribute.	*False*	bool	r	r	r, w
		False	MoMs are not automatically allowed to contact the server with the same privilege as hosts listed in the acl_hosts server attribute.					
acl_hosts List of hosts from which services can be requested of this server. Requests from the server host are always honored whether or not that host is in the list. This list contains the fully qualified domain names of the hosts. List is evaluated left-to-right; first match in list is used.	*String.* Syntax: *"[+|-]<host-name>.<domain>[, ...]"*			No default	pbs.acl	r	r	r, w
acl_resv_group_enable Specifies whether the server obeys the group reservation access control list in the acl_resv_groups server attribute.	*Boolean*		When this attribute is *True*, the server limits group access according to the access control list.	*False*; all groups allowed access	bool	r	r	r, w
acl_resv_groups List of groups allowed or denied permission to create reservations in this PBS complex. The groups in the list are groups on the server host, not submission hosts. List is evaluated left-to-right; first match in list is used.	*String.* Syntax: *"[+|-]<group name>[, ...]"*				pbs.acl	r	r	r, w
acl_resv_host_enable Specifies whether the server obeys the host reservation access control list in the acl_resv_hosts server attribute.	*Boolean*		When this attribute is *True*, the server limits host access according to the access control list.	*False*; access allowed from all hosts	bool	r	r	r, w

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
acl_resv_hosts List of hosts from which reservations can be created in this PBS complex. This list is made up of the fully-qualified domain names of the hosts. List is evaluated left-to-right; first match in list is used.	*String.* Syntax: *"[+|-]<host-name>.<domain>[, ...]"*			No default	pbs.acl	r	r	r, w
acl_resv_user_enable Specifies whether the server limits which users are allowed to create reservations, according to the access control list in the acl_resv_users server attribute.	*Boolean*		When this attribute is *True*, the server limits user reservation creation according to the access control list.	*False*; all users are allowed to create reservations	bool	r	r	r, w
acl_resv_users List of users allowed or denied permission to create reservations in this PBS complex. List is evaluated left-to-right; first match in list is used.	*String.* Syntax: *"[+|-]<user-name>[@<host-name>][, ...]"*			No default	pbs.acl	r	r	r, w
acl_roots List of users with root privilege who can submit and run jobs in this PBS complex. For any job whose owner is root or Administrator, the job owner must be listed in this access control list, or the job is rejected. List is evaluated left-to-right; first match in list is used. Can be set or altered by root only, and only at the server host.	*String.* Syntax: *"[+|-]<user-name>[@<host-name>][, ...]"*			No default; no root jobs allowed	pbs.acl	r	r	r
acl_user_enable Specifies whether the server limits which users are allowed to run commands at the server, according to the control list in the acl_users server attribute.	*Boolean*		When this attribute is *True*, the server limits user access according to the access control list.	*False*; all users have access	bool	r	r	r, w
acl_users List of users allowed or denied permission to run commands at this server. List is evaluated left-to-right; first match in list is used.	*String.* Syntax: *"[+|-]<user-name>[@<host-name>][, ...]"*			No default	pbs.acl	r	r	r, w
backfill_depth Specifies backfilling behavior. Sets the number of jobs that are to be backfilled around. Overridden by backfill_depth queue attribute. Recommendation: set this to less than 100.	*Integer.* Must be >=0	*>=0*	PBS backfills around the specified number of jobs.	Unset. When unset, backfill depth is *1*	int	r	r, w	r, w
		Unset	Backfill depth is set to *1.*					

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
comment Informational text. Can be set by a scheduler or other privileged client.	*String* of any form			No default	str	r	r, w	r, w
default_chunk The list of resources which will be inserted into each chunk of a job's select specification if the corresponding resource is not specified by the user. This provides a means for a site to be sure a given resource is properly accounted for even if not specified by the user.	*String*. Syntax: *default_chunk.<resource name>=<value>,default_chunk.<resource name>=<value>, ...*			No default	pbs.pbs_resource Syntax: *default_chunk["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
default_node No longer used.						-	-	-
default_qdel_arguments Argument to `qdel` command. Automatically added to all `qdel` commands. See `qdel(1B)`. Overrides standard defaults. Overridden by arguments given on the command line.	*String.* Syntax: *"-Wsuppress_mail=<N>"*			No default	pbs.args	r	r, w	r, w
default_qsub_arguments Arguments that are automatically added to the `qsub` command. Any valid arguments to `qsub` command, such as job attributes. Setting a job attribute via default_qsub_arguments sets that attribute for each job which does not explicitly override it. See `qsub(1B)`. Settable by the administrator via the `qmgr` command. Overrides standard defaults. Overridden by arguments given on the command line and in script directives.	*String*. Syntax: *"<option> <value> <option> <value>", e.g. "-r y -N MyJob"* To add to existing: `Qmgr: s s default_qsub_arguments +="<option> <value>"`			No default	pbs.args	r	r, w	r, w
default_queue The name of the default target queue. Used for requests that do not specify a queue name. Must be set to an existing queue.	*Queue name*			*workq*	pbs.queue	r	r, w	r, w
eligible_time_enable Enables accruing job wait time in the job's eligible_time attribute.	*Boolean*	*True* *False*	Job can accrue wait time Job cannot accrue wait time	*False*	bool	r	r	r, w

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
est_start_time_freq **Obsolete**. No longer used.								
flatuid Used for authorization allowing users to submit and alter jobs. Specifies whether user names are treated as being the same across the PBS server and all submission hosts in the PBS complex. Can be used to allow users without accounts at the server host to submit jobs. If UserA has an account at the server host, PBS requires that `UserA@<server host>` is the same as `UserA@<execution host>`.	*Boolean*	*True*	PBS assumes that `UserA@<submithost>` is same user as `UserA@<server name>`. Jobs that run under the name of the job owner do not need authorization. A job submitted under a different username, by using the `u` option to the `qsub` command, requires authorization. Entries in `.rhosts` or `hosts.equiv` are not checked, so even if UserA@host1 has an entry for UserB@host2, UserB@host2 cannot operate on UserA@host1's jobs. User without account on server can submit jobs.	*False*; authorization is required	bool	r	r	r, w
		False	PBS does not assume that `UserA@<submission host>` is the same user as `UserA@<server host>`. Jobs that run under the name of the job owner need authorization. Users must have accounts on the server host to submit jobs.					
FLicenses **Obsolete**. No longer used.								
job_history_duration The length of time PBS will keep each job's history.	*Duration*			*Two weeks*	pbs.duration	r	r	r, w
job_history_enable Enables job history management. Setting this attribute to *True* enables job history management.	*Boolean*			*False*	bool	r	r	r, w

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
job_requeue_timeout The amount of time that can be taken while requeueing a job. Minimum allowed value: 1 second. Maximum allowed value: 3 hours.	Duration			*45 seconds*	pbs.duration	r	r, w	r, w
job_sort_formula Formula for computing job priorities. Described in the *PBS Professional Administrator's Guide*. If the attribute job_sort_formula is set, all schedulers use the formula in it to compute job priorities. When this scheduler sorts jobs according to the formula, it computes a priority for each job, where that priority is the value produced by the formula. Jobs with a higher value get higher priority.	*String*. Syntax: mathematical formula; can be made up of expressions, where expressions contain terms which are added, subtracted, multiplied, or divided, and which can contain parentheses, exponents, unary plus and minus, the ternary operator, and Python math module functions.			Unset	pbs.job_sort_formula	r	r	r, w
jobscript_max_size Limit on the size of any job script.	*size* Units default to bytes			*100MB*	pbs.size	r	r	r, w
license_count The license_count attribute contains the following elements with their values: Avail_Global, Avail_Local, Used, High_Use.	*String.* Syntax: *Avail_Global:<value> Avail_Local:<value> Used:<value> High_Use:<value>*	Avail_Global	The number of licenses available at ALM license server (checked in.)	*Avail_Global:0 Avail_Local:0 Used:0 High_Use:0*	pbs.license_count	r	r	r
		Avail_Local	The number of licenses kept by PBS (checked out.)					
		Used	The number of licenses currently in use.					
		High_Use	The highest number of licenses ever checked out and used by the current instance of the PBS server.					
log_events The types of events the server logs.	*Integer* representation of bit string			*511*	int	r	r, w	r, w
mailer Path to mailer to be used by PBS. This mailer should function similarly to `sendmail`.	*String*			*SENDMAIL_CMD macro*	str	r	r	r, w

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
mail_from The username from which server-generated mail is sent to users. Mail is sent **to** this address upon failover.	*String*			*"adm"*	str	r	r	r, w
managers List of PBS Managers.	*String*. Syntax: *"<user-name>@<host-name>.<subdomain>.<domain>[,<user name>@<host-name>.<subdo-main>.<domain> ...]"*. The host, sub-domain, or domain name may be wildcarded with an asterisk (*).			*Root on the server host*	pbs.acl	r	r	r, w
max_array_size The maximum number of subjobs allowed in any array job.	*Integer*			*10000*	int	r	r, w	r, w
max_concurrent_provision The max_concurrent_provision attribute is the number of vnodes allowed to be in the process of being provisioned. Cannot be set to zero. When unset, default value is used.	*Integer*	>0		5	int	r	r	r, w
max_group_res Old limit attribute. Incompatible with new limit attributes. The maximum amount of the specified resource that any single group may consume in this PBS complex.	*String*. Syntax: *max_group_res.<resource name>=<value>*	Any PBS resource, e.g. "ncpus", "mem", "pmem"		No default	pbs.pbs_resource Syntax: *max_group_res["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
max_group_res_soft Old limit attribute. Incompatible with new limit attributes. The soft limit for the specified resource that any single group may consume in this complex. If a group is consuming more than this amount of the specified resource, their jobs are eligible to be preempted by jobs from groups who are not over their soft limit.	*String*. Syntax: *max_group_res_soft.<resource name>=<value>*	Any PBS resource, e.g. "ncpus", "mem", "pmem", etc.		None	pbs.pbs_resource Syntax: *max_group_res_soft["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
max_group_run Old limit attribute. Incompatible with new limit attributes. The maximum number of jobs owned by the users in one group allowed to be running within this complex at one time.	*Integer*			No default	int	r	r, w	r, w
max_group_run_soft Old limit attribute. Incompatible with new limit attributes. The maximum number of jobs owned by the users in one group allowed to be running in this complex at one time. If a group has more than this number of jobs running, their jobs are eligible to be preempted by jobs from groups who are not over their soft limit.	*Integer*			No default	int	r	r, w	r, w
max_job_sequence_id Maximum value of sequence number in a job ID, job array ID, or reservation ID. Minimum allowed is *9999999*. Maximum allowed is *999999999999*. After specified maximum for sequence number has been reached, job IDs start again at *0*.	*Integer*			*9999999*	int	r	r	r, w
max_queued Limit attribute. The maximum number of jobs allowed to be queued or running in the complex. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Limit specification. See Chapter 7, "Formats", on page 353.			No default	str	r	r, w	r, w

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
max_queued_res Limit attribute. The maximum amount of the specified resource allowed to be allocated to jobs queued or running in the complex. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Limit specification. See Chapter 7, "Formats", on page 353. Syntax: *max_queued_res.<resource name> = "<.limit>"*			No default	pbs.pbs_resource Syntax: *max_queued_res["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
max_run Limit attribute. The maximum number of jobs allowed to be running in the complex. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Limit specification. See Chapter 7, "Formats", on page 353.			No default	str	r	r, w	r, w
max_run_res Limit attribute. The maximum amount of the specified resource allowed to be allocated to jobs running in the complex. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Limit specification. See Chapter 7, "Formats", on page 353 Syntax: *max_run_res.<resource name> = "<.limit>"*			No default	pbs.pbs_resource Syntax: *max_run_res["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
max_run_res_soft Limit attribute. Soft limit on the amount of the specified resource allowed to be allocated to jobs running in the complex. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Limit specification. See Chapter 7, "Formats", on page 353 *max_run_res_soft.<resource name> = "<.limit>"*			No default	pbs.pbs_resource Syntax: *max_run_res_soft["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
max_run_soft Limit attribute. Soft limit on the number of jobs allowed to be running in the complex. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Limit specification. See Chapter 7, "Formats", on page 353.			No default	str	r	r, w	r, w
max_running Old limit attribute. Incompatible with new limit attributes. The maximum number of jobs in this complex allowed to be running at any given time.	*Integer*			No default	int	r	r, w	r, w
max_user_res Old limit attribute. Incompatible with new limit attributes. The maximum amount of the specified resource that any single user may consume within this complex.	*String.* Syntax: *max_user_res.<resource name>=<value>*	Any PBS resource, e.g. "ncpus", "mem", "pmem", etc.		No default	pbs.pbs_resource Syntax: *max_user_res["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
max_user_res_soft Old limit attribute. Incompatible with new limit attributes. The soft limit on the amount of the specified resource that any single user may consume within this complex. If a user is consuming more than this amount of the specified resource, their jobs are eligible to be preempted by jobs from users who are not over their soft limit.	*String.* Syntax: *max_user_res_soft.<resource name>=<value>*	Any valid PBS resource, e.g. "ncpus", "mem", "pmem", etc		No default	pbs.pbs_resource Syntax: *max_user_res_soft["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
max_user_run Old limit attribute. Incompatible with new limit attributes. The maximum number of jobs owned by a single user allowed to be running within this complex at one time.	*Integer*			No default	int	r	r, w	r, w

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
max_user_run_soft Old limit attribute. Incompatible with new limit attributes. The soft limit on the number of jobs owned by a single user that are allowed to be running within this complex at one time. If a user has more than this number of jobs running, their jobs are eligible to be preempted by jobs from users who are not over their soft limit.	*Integer*			No default	int	r	r, w	r, w
node_fail_requeue Controls whether running jobs are automatically requeued or are deleted when the primary execution host fails. Number of seconds to wait after losing contact with Mother Superior before requeueing or deleting jobs. Reverts to default value when server is restarted.	*Integer.* Units: *Seconds.*	*<0*	Behaves as if set to *1*.	*310*	int	r	r, w	r, w
		0	Jobs are not requeued; they are left in the *Running* state until the execution host is recovered.					
		>0	When the host has been down for the specified number of seconds, jobs are requeued if they are marked as rerunnable, or are deleted.					
		Unset	Behaves as if set to default value of *310*.					
node_group_enable Specifies whether placement sets (which includes node grouping) are enabled. See node_group_key server attribute.	*Boolean*		When set to *True*, placement sets are enabled.	*False*	bool	r	r, w	r, w
node_group_key Specifies the resources to use for placement sets (node grouping). Overridden by queue's node_group_key attribute. See node_group_enable server attribute.	*String_array* When specifying multiple resources, separate them with commas and enclose the value in double quotes.			Unset	pbs.node_group_key	r	r, w	r, w

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
operators List of PBS Operators.	*String.* Syntax: *<user-name>@<host-name>.<subdomain>.<domain name>[,<user-name>@<host-name>.<subdomain>.<domain name> ...]*. The host, subdomain, or domain name may be wildcarded with an asterisk (*).			No default	pbs.acl	r	r	r, w
pbs_license_file_location **Deprecated**. Do not use.	-	-	-	-	-	-	-	-
pbs_license_info Location of license server(s).	*String*. Syntax: One or more port number and hostname combinations: *<port1>@<host1>[:<port2>@<host2>:...:<portN>@<host N>]* where *host1*, *host2*, ... *hostN* can be IP addresses. Delimiter between items is colon (":").			No default	str	r	r	r, w
pbs_license_linger_time The number of seconds to keep an unused license, when the number of licenses is above the value given by pbs_license_min.	*Integer*. Units: seconds.			*31536000 seconds (1 year).*	pbs.duration	r	r	r, w
pbs_license_max Maximum number of licenses to be checked out at any time, i.e maximum number of licenses to keep in the PBS local license pool. Sets a cap on the number of nodes or sockets that can be licensed at one time.	*Integer*			Maximum value for an integer	int	r	r	r, w

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
pbs_license_min Minimum number of nodes or sockets to permanently keep licensed, i.e. the minimum number of licenses to keep in the PBS local license pool. This is the minimum number of licenses to keep checked out. If unset, PBS automatically sets the value to *0*.	*Integer*			*0*	int	r	r	r, w
pbs_version The version of PBS for this server.	*String*			No default	pbs.version	r	r	r
power_provisioning Reflects use of power profiles via PBS. Set by PBS to *True* when PBS_power hook is enabled.	*Boolean*	*True* *False*	Power provisioning is enabled. Power provisioning is disabled.	*False*	bool	r	r	r, w
python_restart_max_hooks The maximum number of hooks to be serviced before the Python interpreter is restarted. If this number is exceeded, and the time limit set in python_restart_min_interval has elapsed, the Python interpreter is restarted.	*Integer*			*100*	int	r	r	r, w
python_restart_max_objects The maximum number of objects to be created before the Python interpreter is restarted. If this number is exceeded, and the time limit set in python_restart_min_interval has elapsed, the Python interpreter is restarted.	*Integer*			*1000*	int	r	r	r, w
python_restart_min_interval The minimum time interval before the Python interpreter is restarted. If this interval has elapsed, and either the maximum number of hooks to be serviced (set in python_restart_max_hooks) has been exceeded or the maximum number of objects to be created (set in python_restart_max_objects) has been exceeded, the Python interpreter is restarted.	*Integer*. Units: *Seconds* or *[[HH:]MM:]SS* (duration)			*30*	pbs.duration	r	r	r, w
query_other_jobs Controls whether unprivileged users are allowed to select or query the status of jobs owned by other users.	*Boolean*		When this attribute is *True*, unprivileged users can query or select other users' jobs.	On installation: *True* After being unset: *False*	bool	r	r	r, w

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
queued_jobs_threshold Limit attribute. The maximum number of jobs allowed to be queued in the complex. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Limit specification. See Chapter 7, "Formats", on page 353.			No default	str	r	r, w	r, w
queued_jobs_threshold_res Limit attribute. The maximum amount of the specified resource allowed to be allocated to jobs queued in the complex. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Limit specification. See Chapter 7, "Formats", on page 353. *queued_jobs_threshold_res.<resource name> = "<.limit>"*			No default	pbs.pbs_resource Syntax: *queued_jobs_threshold_res["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
reserve_retry_cutoff **Obsolete**. No longer used.								
reserve_retry_init **Deprecated**. The amount of time after a reservation becomes degraded that PBS waits before attempting to reconfirm the reservation. When this value is changed, only reservations that become degraded after the change use the new value. Must be greater than zero.	*Integer.* Units: *Seconds*			*7200 (2 hours)*	int	-	-	r, w
reserve_retry_time The amount of time after a reservation becomes degraded that PBS waits before attempting to reconfirm the reservation, as well as amount of time between attempts to reconfirm degraded reservations. When this value is changed, PBS uses the new value for any subsequent attempts. Must be greater than zero.	*Integer.* Units: *Seconds*			*600 (10 minutes)*	int	r	r	r, w

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
resources_assigned The total of each type of resource allocated to jobs running and exiting in this complex, plus the total of each type of resource allocated to any reservation. Reservation resources are added when the reservation starts.	*String*. Syntax: *resources_assigned.<resource name>=<value>[,resources_assigned.<resource name>=<value>,...]*			No default	pbs.pbs_resource Syntax: *resources_assigned["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r	r
resources_available The list of available resources and their values defined on the server. Each resource is listed on a separate line.	*String.* Syntax: *resources_available.<resource name>=<value>*			No default	pbs.pbs_resource Syntax: *resources_available["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
resources_cost No longer used.						-	-	-
resources_default The list of default job-wide resource values that are set as limits for jobs in this complex when a) the job does not specify a limit, and b) there is no queue default. The value for a string array, e.g. resources_default.<string array resource>, can contain only one string. For host-level resources, see the default_chunk.<resource name> server attribute.	*String* Syntax: *resources_default.<resource name>=<value>[,...]*			No limit	pbs.pbs_resource Syntax: *resources_default["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
resources_max The maximum amount of each resource that can be requested by any single job in this complex, if there is not a resources_max value defined for the queue at which the job is targeted. This attribute functions as a gating value for jobs entering the PBS complex.	*String* Syntax: *resources_max.<resource name>=<value>[, ...]*			No limit	pbs.pbs_resource Syntax: *resources_max["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
restrict_res_to_release_on_suspend Comma-separated list of consumable resources to be released when jobs are suspended. If unset, all consumable resources are released on suspension.	*String_array* Syntax: comma-separated list			unset	Python list	r	r	r, w
resv_enable Specifies whether or not advance and standing reservations can be created in this complex.	*Boolean*		When set to *True*, new reservations can be created. When changed from *True* to *False*, new reservations cannot be created, but existing reservations are honored.	*True*	bool	r	r	r, w
resv_post_processing_time The amount of time allowed for reservations to clean up after running jobs. Reservation duration and end time are extended by this amount of time. Jobs are not allowed to run during the cleanup period.	*Duration*			Unset; behaves as if zero	int	r	r, w	r, w
rpp_highwater The maximum number of messages.	*Integer*	Greater than or equal to one		*1024*	int	r	r	r, w
rpp_max_pkt_check Maximum number of TPP messages processed by the main server thread per iteration.	Integer			64	int	r	r	r, w
rpp_retry In a fault-tolerant setup (multiple `pbs_comm`s), when the first `pbs_comm` fails partway through a message, this is number of times TPP tries to use the first `pbs_comm`.	*Integer*	Greater than or equal to zero		*10*	int	r	r	r, w

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
scheduler_iteration The time between scheduling iterations.	*Integer.* Units: *Seconds.*			*10 minutes (600 seconds)*	pbs.duration	r	r, w	r, w
scheduling Enables scheduling of jobs. Specified by value of -a option to `pbs_server` command. If -a is not specified, value is taken from previous invocation of `pbs_server`.	*Boolean*		When this attribute is set to *True*, scheduling is enabled.	*False* if never set via `pbs_server` command.	bool	r	r, w	r, w
server_host The name of the host on which the active server is running. If the secondary server takes over, this attribute is set to the name of the secondary server's host. When the primary server takes control again, this attribute shows the name of the primary server's host.	*String*. Syntax: *<host-name>.<domain name>* If the server is listening to a non-standard port, the port number is appended, with a colon, to the hostname: *<host-name>.<domain name>:<port number>*			No default	str	r	r	r

Server Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
server_state The current state of the server:	*String*	*Active*	The server is running. The scheduler is not in a scheduling cycle.	No default	Server state constant pbs.SV_STATE_ACTIVE	r	r	r
		Hot_Start	The server will run first any jobs that were running when it was shut down.		Server state constant pbs.SV_STATE_HOT			
		Idle	The server is running. The default scheduler's scheduling attribute is *False*.		Server state constant pbs.SV_STATE_IDLE			
		Scheduling	The server is running. The scheduler is in a scheduling cycle.		Server state constant pbs.SV_STATE_ACTIVE			
		Terminating	The server is terminating. No additional jobs will be run.		Server state constant pbs.SV_STATE_SHUTIMM or pbs.SV_STATE_SHUTSIG			
		Terminating_Delayed	Server is terminating in delayed mode. No new jobs will be run. server will shut down after all running jobs are finished.		Server state constant pbs.SV_STATE_SHUTDEL			
single_signon_password_enable **Removed**. (2020.1)								
state_count List of the number of jobs in each state in the complex. Suspended jobs are counted as running.	*String.* Syntax: *transiting=<value>, queued=<value>, ...*			No default	pbs.state_count	r	r	r
system_cost No longer used.						-	-	-
total_jobs The total number of jobs in the complex. If the job_history_enable attribute is set to *True*, this includes jobs that are finished, deleted, and moved.	*Integer*			No default	int	r	r	r

6.7 Scheduler Attributes

Scheduler Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
comment For certain scheduler errors, PBS sets the scheduler's comment attribute to specific error messages. You can use the comment attribute to notify another administrator of something, but PBS does overwrite the value of comment under certain circumstances.	*String*			No default	None	r	r	r, w
do_not_span_psets Specifies whether or not this scheduler requires the job to fit within one existing placement set.	*Boolean*	*True*	The job must fit in one existing placement set. All existing placement sets are checked. If the job fits in an occupied placement set, the job waits for the placement set to be available. If the job can't fit within a single placement set, it won't run.	*False*	None	r	r, w	r, w
		False	This scheduler first attempts to place the job in a single placement set. All existing placement sets are checked. If the job fits in an occupied placement set, the job waits for the placement set to be available. If there is no existing placement set, occupied or empty, into which the job could fit, the job runs regardless of placement sets, running on whichever vnodes can satisfy the job's resource request.					
job_sort_formula_threshold Lower bound for calculated priority for job. If job priority is at or below this value, the job is not eligible to run in the current scheduler cycle.	*Float*			No default	None	-	r	r, w
log_events Types of events logged by this scheduler.	*Integer* representation of bit string			767	None	r	r, w	r, w
only_explicit_psets Specifies whether placement sets are created for unset resources.	*Boolean*	*True*	Placement sets are not created from vnodes whose value for a resource is unset.	*False*	None	r	r, w	r, w
		False	Placement sets are created from vnodes whose value for a resource is unset.					

Scheduler Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
opt_backfill_fuzzy Sets the trade-off between scheduling cycle speed and granularity of estimated start time calculation.	*String*	*off*	Finest granularity, no speedup	*unset*; behaves like *low*	None	r	r	r, w
		low	Fairly fine granularity, some speedup					
		medium	Medium granularity, medium speedup					
		high	Coarse granularity, greatest speedup					
partition Name of partition for which this scheduler is to run jobs. Cannot be set on default scheduler.	*String*			"*None*"	None	r	r	r, w
pbs_version The version of PBS for this scheduler.	*String*			No default	None	-	r	r
preempt_order Defines the order of preemption methods which this scheduler uses on jobs. This order can change depending on the percentage of time remaining on the job. The ordering can be any combination of *S, C, R,* and *D.* Usage: an ordering (*SCR*) optionally followed by a percentage of time remaining and another ordering. For example, PBS should first attempt to use suspension to preempt a job, and if that is unsuccessful, requeue the job: `preempt_order: "SR"` For example, if the job has between 100% and 81% of requested time remaining, first try to suspend the job, then try checkpoint, then requeue. If the job has between 80% and 51% of requested time remaining, attempt suspend, then checkpoint. Between 50% and 0% time remaining, just attempt to suspend the job: `preempt_order: "SCR 80 SC 50 S"` For each job percentage, each method can be used only once. Note that in the example above, the *S* method appears only once per percentage.	*String, as a quoted list*	*C*	Checkpoint job	"*SCR*"		r	r	r, w
		D	Delete job					
		R	Requeue job					
		S	Suspend job					

Scheduler Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
preempt_prio Specifies the ordering of priority for different preemption levels. Two or more job types may be combined at the same priority level with a plus sign ("+") between them, using no whitespace. Comma-separated preemption levels are evaluated left to right, with higher priority to the left. Any level not specified in the preempt_prio list is ignored. For example, express jobs have the highest priority, then normal jobs, and jobs whose entities are over their fairshare limit are third highest: `preempt_prio: "express_queue, normal_jobs, fairshare"` For example, express jobs whose entities are also over their fairshare limit are lower priority than normal jobs: `preempt_prio: "normal_jobs, express_queue+fairshare"`	*string_array, as quoted list*	express_queue	Jobs in express queues preempt other jobs. See preempt_queue_prio. Does not require by_queue to be *True*.	"*express_queue, normal_jobs*"	None	r	r	r, w
		fairshare	When the entity owning a job exceeds its fairshare limit.					
		queue_softlimits	Jobs which are over their queue soft limits					
		server_softlimits	Jobs which are over their server soft limits					
		normal_jobs	The preemption level into which a job falls if it does not fit into any other specified level.					
preempt_queue_prio Specifies the minimum queue priority required for a queue to be classified as an express queue. Express queues do not require by_queue to be *True*.	*Integer*			*150*	None	r	r	r, w
preempt_sort Specifies how jobs most eligible for preemption are sorted. See "Sorting Within Preemption Level" on page 186 in the PBS Professional Administrator's Guide.	*String*	*min_time_since_start*	First job preempted will be that with most recent start time	*min_time_since_start*	None	r	r	r, w
scheduler_iteration Time in seconds between scheduling iterations. If you set the server's scheduler_iteration attribute, that value is assigned to the default scheduler's scheduler_iteration attribute, and vice versa.	*Integer*. Units: *Seconds*			*600*	None	r	r	r, w
scheduling Enables scheduling of jobs. If you set the server's scheduling attribute, that value is assigned to the default scheduler's scheduling attribute, and vice versa.	*Boolean*			For default scheduler: *True* For multischeds: *False*	None	r	r	r, w

Scheduler Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
sched_cycle_length This scheduler's maximum cycle length. Overwritten by the -a alarm option to pbs_sched command.	*Duration*			*20:00* (20 minutes)	None	r	r, w	r, w
sched_host The hostname of the machine on which this scheduler runs. Default value for default scheduler is set by server to server hostname. For a multisched, must be set by administrator.	*String*			*Server's host*	None	-	r	r
sched_log Directory where this scheduler writes its logs. Permissions should be *755*. Must be owned by root. Cannot be shared with another scheduler. For default scheduler, directory is always PBS_HOME/sched_log. Settable for multischeds.	*String*			*$PBS_HOME/sched_logs_<scheduler name>*	None	r	r	r, w
sched_preempt_enforce_resumption Controls whether this scheduler treats preempted jobs as top jobs. When *True*, preempted jobs are treated as top jobs.	*Boolean*			False	None	r	r	r, w
sched_priv Directory where this scheduler keeps fairshare usage, resource_group, holidays, and sched_config files. Must be owned by root. For default scheduler, directory is always PBS_HOME/sched_priv. Settable for multischeds.	*String*			*$PBS_HOME/sched_priv_<scheduler name>*	None	r	r	r, w
server_dyn_res_alarm Specifies how long this scheduler allows any server_dyn_res script to run. If the script times out, the script is terminated and the scheduler uses zero as the value that would have been returned by the script.	*Integer*	*0 (zero)*	No time limit is enforced for server_dyn_res scripts	*30 seconds*	None	r	r	r, w
		>0 (greater than zero)	Value is number of seconds any server_dyn_res script is allowed to run					
state State of this scheduler. Set by server.	*String*	*down*	Scheduler is not running	For default scheduler: idle For multi-sched: down	None	r	r	r
		idle	Scheduler is running and is waiting for a scheduling cycle to be triggered					
		scheduling	Scheduler is running and is in a scheduling cycle					

Scheduler Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	User	Oper	Mgr
throughput_mode Allows scheduler to run faster; it doesn't have to wait for each job to be accepted, and doesn't wait for execjob_begin hooks to finish. Also allows jobs that were changed via `qalter`, server_dyn_res scripts, or peering to run in the same scheduling cycle where they were changed.	*Boolean*	*True*	Scheduler runs asynchronously and faster. Only available when PBS complex is in TPP mode.	True	None	r	r, w	r, w
		False	Scheduler does not run asynchronously					

6.8 Reservation Attributes

Reservation Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	User	Oper	Mgr
Account_Name No longer used.						-	-	-
Authorized_Groups List of groups who can or cannot submit jobs to this reservation. Group names are interpreted relative to the server, not the submission host. List is evaluated left-to-right; first match in list is used. This list is used to set the reservation queue's acl_groups attribute. See the G option to the pbs_rsub command.	*String.* Syntax: *[+|-]<group name> [, [+|-]<group name> ...]* where '-' means "deny" and '+' means "allow".			No default. (Jobs can be submitted by all groups)	pbs.acl	r, w	r, w	r, w
Authorized_Hosts The list of hosts from which jobs can and cannot be submitted to this reservation. List is evaluated left-to-right; first match in list is used. This list is used to set the reservation queue's acl_hosts attribute. See the H option to the pbs_rsub command.	*String.* Syntax: *[+|-]<hostname> [, [+|-]<hostname> ...]* where '-' means "deny" and '+' means "allow". Hostnames may be wildcarded using an asterisk, according to the following rules: A hostname can contain at most one asterisk The asterisk must be the leftmost label Examples: `*.test.example.com` `*.example.com` `*.com`			No default. (Jobs can be submitted from all hosts)	pbs.acl	r, w	r, w	r, w

Reservation Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	User	Oper	Mgr
Authorized_Users The list of users who can or cannot submit jobs to this reservation. List is evaluated left-to-right; first match in list is used. This list is used to set the reservation queue's acl_users attribute. See the `U` option to the `pbs_rsub` command.	*String*. Syntax: *[+|-]<username>[@<hostname>.<domain>] [, [+|-]<username>[@<hostname>.<domain>] ...]* where '-' means "deny" and '+' means "allow". Hostnames may be wildcarded using an asterisk, according to the following rules: A hostname can contain at most one asterisk The asterisk must be the leftmost label in the hostname Examples: `*.test.example.com` `*.example.com` `*.com`			Reservation owner only	pbs.acl	r, w	r, w	r, w
ctime Timestamp; time at which the reservation was created.	*Timestamp.* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.			No default	int	r	r	r
delete_idle_time Amount of time a reservation can sit idle before it is deleted. Applies to each instance of a standing reservation.	*Duration*. Syntax: either *integer seconds* or *HHHH:MM:SS*			None except for ASAP reservations: *10 minutes*	pbs.duration	r, w	r, w	r, w

Reservation Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	User	Oper	Mgr
group_list No longer used.						-	-	-
hashname No longer used.						-	-	-
interactive Number of seconds that the `pbs_rsub` command will block while waiting for confirmation or denial of the reservation. See the `-I block_time` option to the `pbs_rsub` command.	*Integer*	Less than zero	The reservation is automatically deleted if it cannot be confirmed in the time specified.	*Zero*	int	r, w	r, w	r, w
		Zero or greater than zero	The reservation is not automatically deleted if it cannot be confirmed in the time specified.					
Mail_Points Sets the list of events for which mail is sent by the server. Mail is sent to the list of users specified in the Mail_Users attribute. See the `m mail_points` option to the `pbs_rsub` command.	*String* consisting of 1) one or more of the letters "*a*", "*b*", "*c*", "*e*", or *2*) the string "*n*". Cannot use "*n*" with any other letter	*a*	Notify when reservation is terminated	"*ac*"	pbs.mail_points	r, w	r, w	r, w
		b	Notify when reservation period begins					
		c	Notify when reservation is confirmed					
		e	Notify when reservation period ends					
		n	Do not send mail. Cannot be used with other letters.					
Mail_Users The set of users to whom mail is sent for the reservation events specified in the Mail_Points attribute. See the `M mail_list` option to the `pbs_rsub` command.	*String.* Syntax: *<username>@<hostname>[,<username>@<hostname>, ...]*			Reservation owner only	pbs.user_list	r, w	r, w	r, w

Reservation Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	User	Oper	Mgr
mtime Timestamp: the time that the reservation was last modified.	*Timestamp.* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.				int	r	r	r
Priority No longer used.						-	-	-
queue Name of the reservation queue. Jobs that are to use resources belonging to this reservation are submitted to this queue.	*String*. Format for an advance or job-specific reservation: *R<sequence number>* Format for a standing reservation: *S<sequence number>*				pbs.queue	r	r	r
reserve_count The count of occurrences in a standing reservation.	*Integer*				int	r, w	r, w	r, w
reserve_duration Reservation duration in seconds. For a standing reservation, this is the duration for one occurrence.	*Integer*				pbs.duration	r, w	r, w	r, w
reserve_end The date and time when an advance reservation or the soonest occurrence of a standing reservation ends.	*Timestamp.* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.				int	r, w	r, w	r, w
reserve_ID The reservation identifier.	*String*. For an advance or job-specific reservation: string of the form *R<sequence number>.<server name>* For a standing reservation: string of the form *S<sequence number>.<server name>*				str	r	r	r

Reservation Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	User	Oper	Mgr
reserve_index The index of the soonest occurrence of a standing reservation.	*Integer*				int	r	r	r
reserve_job If this reservation is a job-specific start or now reservation, shows the ID of the job from which the reservation was created.	*String*			No default	str	r	r	r
Reserve_Name The name assigned to the reservation during creation, if specified. See the `N` option to the `pbs_rsub` command.	*String*. Syntax: up to 236 characters. First character is alphabetic			No default	str	r, w	r, w	r, w
Reserve_Owner The login name on the submission host of the user who created the reservation.	*String.* Syntax: <*username*>@<*hostname*>			Login name of creator	str	r	r	r
reserve_retry If this reservation becomes degraded, this is the next time that PBS will attempt to reconfirm this reservation.	*Timestamp.* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.			No default	int	r	r	r

Reservation Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	User	Oper	Mgr
reserve_rrule The rule that describes the recurrence pattern of a standing reservation. See the `r` option to the `pbs_rsub` command.	*String*. Syntax: either of two forms: *"FREQ= <freq_spec>; COUNT= <count_spec>; <interval_spec>"* or *"FREQ= <freq_spec>; UNTIL= <until_spec>; <interval_spec>"*	*freq_spec*	Frequency with which the standing reservation repeats. Valid values are: *WEEKLY|DAILY|HOURLY*	No default	str	r, s	r, w	r, w
		count_spec	The exact number of occurrences. Number up to 4 digits in length. Format: *integer*.	No default				
		interval_spec	Specifies interval. Format is one or both of: *BYDAY = MO|TU|WE|TH|FR|SA|SU or BYHOUR = 0|1|2|...|23*	No default				
		until_spec	Occurrences will start up to but not after date and time specified. Format: *YYYYMMDD[THHMMSS]* Year-month-day part and hour-minute-second part separated by a capital *T*.	No default				
reserve_start The date and time when the reservation period for the reservation or soonest occurrence begins.	*Timestamp.* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.			No default	int	r, w	r, w	r, w

Reservation Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	User	Oper	Mgr
reserve_state The state of the reservation.	*String*	*NO RESV_NONE*	No reservation yet.	No default	Reservation state constant: pbs.RESV_STATE_NONE	r	r	r
		UN RESV_UNCONFIRMED	Reservation request is awaiting confirmation.		Reservation state constant: pbs.RESV_STATE_UNCONFIRMED			
		CO RESV_CONFIRMED	Resv. confirmed. All occurrences of standing resv. confirmed.		Reservation state constant: pbs.RESV_STATE_CONFIRMED			
		WT RESV_WAIT	Unused.		Reservation state constant: pbs.RESV_STATE_WAIT			
		TR RESV_TIME_TO_RUN	Start of the reservation period.		Reservation state constant: pbs.RESV_STATE_TIME_TO_RUN			
		RN RESV_RUNNING	Resv. period has started; reservation is running.		Reservation state constant: pbs.RESV_STATE_RUNNING			
		FN RESV_FINISHED	End of the reservation period.		Reservation state constant: pbs.RESV_STATE_FINISHED			
		BD RESV_BEING_DELETED	Reservation is being deleted.		Reservation state constant: pbs.RESV_STATE_BEING_DELETED			
		DE RESV_DELETED	Reservation has been deleted.		Reservation state constant: pbs.RESV_STATE_DELETED			
		DJ RESV_DELETING_JOBS	Jobs belonging to the reservation are being deleted		Reservation state constant: pbs.RESV_STATE_DELETING_JOBS			
		DG DEGRADED	Reservation is degraded.		Reservation state constant: pbs.RESV_STATE_DEGRADED			
reserve_substate The substate of the reservation or occurrence. The substate is used internally by PBS.	*Integer*			No default	int	r	r	r
reserve_type No longer used.						-	-	-

Reservation Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	User	Oper	Mgr
Resource_List The list of resources allocated to the reservation. Jobs running in the reservation cannot use in aggregate more than the specified amount of a resource.	*String*. Syntax: *Resource_List.<resource name>=<value>[, Resource_List.<resource name>=<value>, ...]*			No default	pbs.pbs_resource Syntax: *Resource_List["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r, w	r, w	r, w
resv_nodes The list of each vnode and the resources allocated from it to satisfy the chunks requested for this reservation or occurrence. For a maintenance reservation, value is set by PBS.	*String*. Syntax: *(<vnode name>:<resource name>=<value>[:<resource name>=<value>]...)[+(<vnode name>:<resource name>=<value>[:<resource name>=<value>])+...]*			No default	pbs.exec_vnode	r	r	r
server Name of server.	*String*			No default	pbs.server	r	r	r
User_List No longer used.						-	-	-
Variable_List Not used						-	-	-

6.9 Queue Attributes

In the following table, Queue Type indicates the type of queue to which the attribute applies: R (routing), E (execution):

Queue Attributes									
Name Description	Format	Queue Type	Value or Option	Value or Option Description	Default Value	Python Type	User	Oper	Mgr
acl_group_enable Controls whether group access to the queue obeys the access control list defined in the acl_groups queue attribute.	*Boolean*	R, E		When set to *True*, group access to the queue is limited according to the group access control list.	*False*; all groups allowed access	bool	r	r, w	r, w
acl_groups List of groups which are allowed or denied access to this queue. The groups in the list are groups on the server host, not submitting hosts. List is evaluated left-to-right; first match in list is used.	*String*. Syntax: *[+|-] <group name>[, ...]*	R, E			No default	pbs.acl	r	r, w	r, w
acl_host_enable Controls whether host access to the queue obeys the access control list defined in the acl_hosts queue attribute.	*Boolean*	R, E		When set to *True*, host access to the queue is limited according to the host access control list.	*False*; all hosts allowed access.	bool	r	r, w	r, w
acl_hosts List of hosts from which jobs may be submitted to this queue. List is evaluated left-to-right; first match in list is used.	*String.* Syntax: *[+|-]<hostname>[. ...]*	R, E			No default	pbs.acl	r	r, w	r, w
acl_user_enable Controls whether user access to the queue obeys the access control list defined in the acl_users queue attribute.	*Boolean*	R, E		When set to *True*, user access to the queue is limited according to the user access control list.	*False*; all users allowed access	bool	r	r, w	r, w
acl_users List of users allowed or denied access to this queue. List is evaluated left-to-right; first match in list is used.	*String.* Syntax: *[+|-]<username> [@<hostname>][, ...]*	R, E			No default	pbs.acl	r	r, w	r, w
alt_router No longer used.							-	-	-
backfill_depth Specifies backfilling behavior for this queue. Sets the number of jobs that are to be backfilled around in this queue. Overrides backfill_depth server attribute. Recommendation: set this to less than 100.	*Integer.* Must be >=0.	E	*>=0*	PBS backfills around the specified number of jobs.	Unset. When unset, backfill depth is *1*	int	r, w	r, w	r, w
			Unset	Backfill depth is set to *1*					

Queue Attributes									
Name Description	Format	Queue Type	Value or Option	Value or Option Description	Default Value	Python Type	User	Oper	Mgr
checkpoint_min Minimum number of minutes of CPU time or walltime allowed between checkpoints of a job. If a user specifies a time less than this value, this value is used instead. The value given in checkpoint_min is used for both CPU minutes and walltime minutes.	*Integer*	E			No default	pbs.duration	r	r, w	r, w
default_chunk The list of resources which will be inserted into each chunk of a job's select specification if the corresponding resource is not specified by the user. This provides a means for a site to be sure a given resource is properly accounted for even if not specified by the user.	*String.* Syntax: *default_chunk.<resource name>=<value>[, default_chunk.<resource name>=<value>, ...]*	E			No default	pbs.pbs_resource Syntax: *default_chunk["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
enabled Specifies whether this queue accepts new jobs.	*Boolean*	R, E	*True*	This queue is *enabled*. This queue accepts new jobs; new jobs can be enqueued.	*False*	bool	r	r, w	r, w
			False	This queue does not accept new jobs.					
from_route_only Specifies whether this queue accepts jobs only from routing queues, or from both execution and routing queues.	*Boolean*	R, E	*True*	This queue accepts jobs only from routing queues.	*False*	bool	r	r	r, w
			False	This queue accepts jobs from both execution and routing queues as well as directly from submitter.					
hasnodes **Deprecated**. Indicates whether vnodes are associated with this queue. Set by PBS.	*Boolean*	E		This attribute is set to *True* if there are vnodes associated with this queue.	*False*; no vnodes are associated with this queue	bool	r	r	r, i

Queue Attributes									
Name Description	Format	Queue Type	Value or Option	Value or Option Description	Default Value	Python Type	User	Oper	Mgr
kill_delay The time delay between sending SIGTERM and SIGKILL when a `qdel` command is issued against a running job.	*Integer*. Units: *Seconds*. Must be greater than or equal to *zero*.	E			*10 seconds*	pbs.duration	r	r, w	r, w
max_array_size The maximum number of subjobs that are allowed in an array job.	*Integer*	R, E			No default	int	r	r, w	r, w
max_group_res Old limit attribute. Incompatible with new limit attributes. The maximum amount of the specified resource that any single group may consume in a complex.	*String.* Syntax: *max_group_res.<resource name>=<value>* Example: `set queue workq max_group_res.ncpus=6`	E	Any PBS resource, e.g. "ncpus", "mem", "pmem", etc.		No default	pbs.pbs_resource Syntax: *max_group_res["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
max_group_res_soft Old limit attribute. Incompatible with new limit attributes. The soft limit on the amount of the specified resource that any single group may consume in a complex. If a group is consuming more than this amount of the specified resource, their jobs are eligible to be preempted by jobs from groups who are not over their soft limit.	*String.* Syntax: *max_group_res_soft.<resource name>=<value>* Example: `set queue workq max_group_res_soft.ncpus=3`	E	Any valid PBS resource, e.g. "ncpus", "mem", "pmem", etc.		No default	pbs.pbs_resource Syntax: *max_group_res_soft["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
max_group_run Old limit attribute. Incompatible with new limit attributes. The maximum number of jobs owned by users in a single group that are allowed to be running from this queue at one time.	*Integer*	E			No default	int	r	r, w	r, w
max_group_run_soft Old limit attribute. Incompatible with new limit attributes. The maximum number of jobs owned by users in a single group that are allowed to be running from this queue at one time. If a group has more than this number of jobs running, their jobs are eligible to be preempted by jobs from groups who are not over their soft limit.	*Integer*	E			No default	int	r	r, w	r, w

Queue Attributes									
Name Description	Format	Queue Type	Value or Option	Value or Option Description	Default Value	Python Type	User	Oper	Mgr
max_queuable Old limit attribute. Incompatible with new limit attributes. The maximum number of jobs allowed to reside in this queue at any given time.	*Integer*	R, E			No default (no limit)	int	r	r, w	r, w
max_queued Limit attribute. The maximum number of jobs allowed to be queued in or running from this queue. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Limit specification. See Chapter 7, "Formats", on page 353	R, E			No default	pbs.pbs_resource Syntax: *max_queued["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
max_queued_res Limit attribute. The maximum amount of the specified resource allowed to be allocated to jobs queued in or running from this queue. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Limit specification. See Chapter 7, "Formats", on page 353 Syntax: *max_queued_res.<resource name>=<value>*	R, E			No default	pbs.pbs_resource Syntax: *max_queued_res["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
max_run Limit attribute. The maximum number of jobs allowed to be running from this queue. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Format: *Limit specification*. See Chapter 7, "Formats", on page 353	E			No default	pbs.pbs_resource Syntax: *max_run["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
max_run_res Limit attribute. The maximum amount of the specified resource allowed to be allocated to jobs running from this queue. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Format: Limit specification. See Chapter 7, "Formats", on page 353. Syntax: *max_run_res.<resource name>=<value>*	E			No default	pbs.pbs_resource Syntax: *max_run_res["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w

Queue Attributes									
Name Description	Format	Queue Type	Value or Option	Value or Option Description	Default Value	Python Type	User	Oper	Mgr
max_run_res_soft Limit attribute. Soft limit on the amount of the specified resource allowed to be allocated to jobs running from this queue. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Format: Limit specification. See Chapter 7, "Formats", on page 353. Syntax: *max_run_res_soft.<resource name>=<value>*	E			No default	pbs.pbs_resource Syntax: *max_run_res_soft["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
max_run_soft Limit attribute. Soft limit on the number of jobs allowed to be running from this queue. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Limit specification. See Chapter 7, "Formats", on page 353.	E			No default	pbs.pbs_resource Syntax: *max_run_soft["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
max_running Old limit attribute. Incompatible with new limit attributes.For an execution queue, this is the largest number of jobs allowed to be running at any given time. For a routing queue, this is the largest number of jobs allowed to be transiting from this queue at any given time.	*Integer*	R, E			No default	int	r	r, w	r, w
max_user_res Old limit attribute. Incompatible with new limit attributes. The maximum amount of the specified resource that any single user may consume.	*String.* Syntax: *max_user_res.<resource name>=<value>* Example: `set queue workq max_user_res.ncpus=6`	E	any PBS resource, e.g. "ncpus", "mem", "pmem", etc		No default	pbs.pbs_resource Syntax: *max_user_res["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
max_user_res_soft Old limit attribute. Incompatible with new limit attributes. The soft limit on the amount of the specified resource that any single user may consume. If a user is consuming more than this amount of the specified resource, their jobs are eligible to be preempted by jobs from users who are not over their soft limit.	*String.* Syntax: *max_user_res_soft.<resource name>=<value>* Example: `set queue workq max_user_res_soft.ncpus=3`	E	any valid PBS resource, e.g. "ncpus", "mem", "pmem", etc		No default	pbs.pbs_resource Syntax: *max_user_res_soft["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w

Queue Attributes									
Name Description	Format	Queue Type	Value or Option	Value or Option Description	Default Value	Python Type	User	Oper	Mgr
max_user_run Old limit attribute. Incompatible with new limit attributes. The maximum number of jobs owned by a single user that are allowed to be running from this queue at one time.	*Integer*	E			No default	int	r	r, w	r, w
max_user_run_soft Old limit attribute. Incompatible with new limit attributes. The soft limit on the number of jobs owned by any single user that are allowed to be running from this queue at one time. If a user has more than this number of jobs running, their jobs are eligible to be preempted by jobs from users who are not over their soft limit.	*Integer*	E			No default	int	r	r, w	r, w
node_group_key Specifies the resources to use for placement sets (node grouping). Overrides server's node_group_key attribute. Specified resources must be of type string_array.	*String_array.* Syntax: Comma-separated list of resource names. When specifying multiple resources, enclose value in double quotes.	R, E			No default	pbs.node_group_key	r	r, w	r, w
partition Name of partition to which this queue is assigned. Cannot be set for routing queue. An execution queue cannot be changed to a routing queue while this attribute is set.	*String*	E			No default	str	r	r	r, w
Priority The priority of this queue compared to other queues of the same type in this PBS complex. Priority can define a queue as an express queue. See preempt_queue_prio in Chapter 4, "Scheduler Parameters", on page 251. Used for execution queues only; the value of Priority has no meaning for routing queues.	*Integer*	E	Valid values: *-1024 to 1023*		No default	int	r	r, w	r, w
queued_jobs_threshold Limit attribute. The maximum number of jobs allowed to be queued in this queue. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Limit specification. See Chapter 7, "Formats", on page 353.	R, E			No default	pbs.pbs_resource Syntax: *queued_jobs_threshold["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w

Queue Attributes									
Name Description	Format	Queue Type	Value or Option	Value or Option Description	Default Value	Python Type	User	Oper	Mgr
queued_jobs_threshold_res Limit attribute. The maximum amount of the specified resource allowed to be allocated to jobs queued in this queue. Can be specified for projects, users, groups, or all. Cannot be used with old limit attributes.	Limit specification. See Chapter 7, "Formats", on page 353. Syntax: *"queued_jobs_threshold_res.<resource name>=<value>"*	R, E			No default	pbs.pbs_resource Syntax: *queued_jobs_threshold_res["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
queue_type The type of this queue. This attribute must be explicitly set at queue creation.	*String*	R, E	*"e", "execution*	Execution queue	No default	PBS queue type constant: pbs.QUEUETYPE_EXECUTION	r	r, w	r, w
			"r", "route"	Routing queue		PBS queue type constant: pbs.QUEUETYPE_ROUTE			
require_cred **Obsolete** (2020.1) Specifies the credential type required. All jobs submitted to the named queue without the specified credential will be rejected.	*String*	R, E	*krb5*		unset	str	r	r	r, w
			dce						
require_cred_enable **Obsolete** (2020.1) Specifies whether the credential authentication method specified in the require_cred queue attribute is required for this queue.	*Boolean*	R, E		When set to *True*, the credential authentication method is required.	*False*	bool	r	r	r, w
resources_assigned The total for each kind of resource allocated to running and exiting jobs in this queue.	*String.* Syntax: *resources_assigned.<resource name>=<value><newline>resources_assigned.<resource name>=<value><newline>...*	E			No default	pbs.pbs_resource Syntax: *resources_assigned["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r	r

Queue Attributes									
Name Description	Format	Queue Type	Value or Option	Value or Option Description	Default Value	Python Type	User	Oper	Mgr
resources_available The list of resources and amounts available to jobs running in this queue. The sum of the resource of each type used by all jobs running from this queue cannot exceed the total amount listed here.	*String.* Syntax: *resources_available.<resource name>=<value><newline> resources_available.<resource name>=<value><newline>...*	E			No default	pbs.pbs_resource Syntax: *resources_available["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
resources_default The list of default resource values which are set as limits for a job residing in this queue and for which the job did not specify a limit. If not set, the default limit for a job is determined by the first of the following attributes which is set: server's resources_default, queue's resources_max, server's resources_max. If none of these is set, the job gets unlimited resource usage.	*String.* Syntax: *resources_default.<resource name>=<value>, resources_default.<resource_name>=<value>, ...*	R, E			No default	pbs.pbs_resource Syntax: *resources_default["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
resources_max The maximum amount of each resource that can be requested by a single job in this queue. This queue value supersedes any server wide maximum limit.	*String.* Syntax: *resources_max.<resource name>=<value>, resources_max.<resource name>=<value>, ...*	R, E			No default; infinite usage	pbs.pbs_resource Syntax: *resources_max["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w
resources_min The minimum amount of each resource that can be requested by a single job in this queue.	*String.* Syntax: *resources_max.<resource_name>=<value>, resources_max.<resource name>=<value>, ...*	R, E			No default; zero usage	pbs.pbs_resource Syntax: *resources_min["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r, w	r, w

Queue Attributes									
Name Description	Format	Queue Type	Value or Option	Value or Option Description	Default Value	Python Type	User	Oper	Mgr
route_destinations The list of destinations to which jobs may be routed. Must be set to at least one valid destination.	*String.* Syntax: comma-separated strings: *<queue name> [@<server host> [:port]]* Example: `Q1, Q2@remote, Q3@remote:15501`	R			No default	pbs.route_destinations	r	r	r, w
route_held_jobs Specifies whether jobs in the held state can be routed from this queue.	*Boolean*	R		When *True*, jobs with a hold can be routed from this queue.	*False*	bool	r	r, w	r, w
route_lifetime The maximum time a job is allowed to reside in this routing queue. If a job cannot be routed in this amount of time, the job is aborted.	*Integer.* Units: *Seconds*	R	*>0*	Jobs can reside for specified number of seconds	Unset; infinite	pbs.duration	r	r, w	r, w
			0	Infinite					
			unset	Infinite					
route_retry_time Time delay between routing retries. Typically used when the network between servers is down.	*Integer.* Units: *Seconds*	R			*30 seconds*	pbs.duration	r	r, w	r, w
route_waiting_jobs Specifies whether jobs whose Execution_Time attribute value is in the future can be routed from this queue.	*Boolean*	R		When *True*, jobs with a future Execution_Time attribute can be routed from this queue.	*False*	bool	r	r, w	r, w
started If this is an execution queue, specifies whether jobs in this queue can be scheduled for execution, or if this is a routing queue, whether jobs can be routed.	*Boolean*	R, E		When *True*, jobs in this queue can run or be routed	*False*	bool	r	r, w	r, w
state_count The number of jobs in each state currently residing in this queue.	*String.* Syntax: *transiting=<value>, exiting=<value>, ...*	R, E			No default	pbs.state_count	r	r	r
total_jobs The number of jobs currently residing in this queue.	*Integer*	R, E			No default	int	r	r	r

6.10 Vnode Attributes

Vnode Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
comment Information about this vnode. This attribute may be set by the manager to any string to inform users of any information relating to the node. If this attribute is not explicitly set, the PBS server will use the attribute to pass information about the node status, specifically why the node is down. If the attribute is explicitly set by the manager, it will not be modified by the server.	*String* Limit: 80 characters			No default	str	r	r	r, w
current_aoe The AOE currently instantiated on this vnode. Case-sensitive. Cannot be set on server's host.	*String*			Unset	str	r	r	r, w
current_eoe Current value of eoe on this vnode. We do not recommend setting this attribute manually.	*String*			Unset	str	r	r	r, w
in_multivnode_host Specifies whether a vnode is part of a multi-vnoded host. Used internally. Do not set.	*Integer*	*Unset*	Not part of a multi-vnode host		int			r, w
		1	Part of a multi-vnode host					
jobs List of jobs running on this vnode.	*String*. Syntax: *<processor number>/<job ID>, ...*				str	r	r	r
last_state_change_time Records the most recent time that this node changed state.	*Timestamp.* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.			No default	int	r	r, w	r, w

Vnode Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
last_used_time Records the most recent time that this node finished being used for a job or reservation. Set at creation or reboot time. Updated when node is released early from a running job. Reset when node is ramped up.	*Timestamp.* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.			Time of vnode creation or node reboot.	int	r	r, w	r, w
license Indicates whether this vnode is licensed. Set by PBS.	*Character*	*l*	This vnode is licensed.	Unset	str	r	r	r
license_info Number of licenses assigned to this vnode. Set by PBS.	*Integer*			Unset	int	r	r	r
lictype No longer used.					none	-	-	-
maintenance_jobs List of jobs that were running on this vnode, but have been suspended via the *admin-suspend* signal to `qsig`. Set by server.	*String_array*			No default	str	-	-	r
Mom Hostname where server queries for MoM host. By default the server queries the canonicalized name of the MoM host, unless you set this attribute when you create the vnode. Can be explicitly set by Manager only via `qmgr`, and only at vnode creation. The server can set this to the FQDN of the host on which MoM runs, if the vnode name is the same as the hostname.	*String*		.	Value of vnode resource (vnode name)	str	r	r	r, w
name The name of this vnode.	*String*			No default	str	r	r	r, w

Vnode Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
no_multinode_jobs Controls whether jobs which request more than one chunk are allowed to execute on this vnode. Used for cycle harvesting.	*Boolean*		When set to *True*, jobs requesting more than one chunk are not allowed to execute on this vnode	*False*	bool	r	r	r, w
ntype The type of this vnode.	*String*	*PBS*	Normal vnode	*PBS*	pbs.ND_PBS	r	r	r
partition Name of partition to which this vnode is assigned. A vnode can be assigned to at most one partition.	*String*			No default	str	r	r, w	r, w
pbs_version The version of PBS for this MoM	*String*			No default	str	r	r	r
pcpus **Deprecated**. The number of physical CPUs on this vnode. This is set to the number of CPUs available when MoM starts. For a multiple-vnode MoM, only the parent vnode has pcpus.	*Integer*			Number of CPUs on start-up	int	r	r	r
pnames The list of resources being used for placement sets. Not used for scheduling; advisory only.	*String*. Syntax: comma-separated list of resource names.			No default	str	r	r	r, w
Port Port number on which MoM daemon listens. Can be explicitly set only via `qmgr`, and only at vnode creation.	*Integer*			*15002*	int	-	r, w	r, w
poweroff_eligible Enables powering this vnode up and down by PBS.	*Boolean*	*True* *False*	PBS can power this vnode on and off. PBS cannot power this vnode on and off.	*False*	bool	r	r	r, w
power_provisioning Specifies whether this node is eligible to have its power managed by PBS, including whether it can use power profiles.	*Boolean*	*True* *False*	Power provisioning is enabled at this vnode. Power provisioning is disabled at this vnode.	*False*	bool	r	r	r, w

Vnode Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
Priority The priority of this vnode compared with other vnodes.	*Integer*	*[-1024, +1023]* inclusive		No default	int	r	r, w	r, w
provision_enable Controls whether this vnode can be provisioned. Cannot be set on server's host.	*Boolean*	*True*	This vnode may be provisioned.	*False*	bool	r	r	r, w
		False	This vnode may not be provisioned.					
queue **Deprecated**. The queue with which this vnode is associated. Each vnode can be associated with at most 1 queue. Queues can be associated with multiple vnodes. Any jobs in a queue that has associated vnodes can run only on those vnodes. If a vnode has an associated queue, only jobs in that queue can run on that vnode.	*String*	*<name of queue>*	Only jobs in specified queue may run on this vnode.	No default	pbs.queue	r	r	r, w
		Unset	Any job in any queue that does not have associated vnodes can run on this vnode.					
resources_assigned The total amount of each resource allocated to running and exiting jobs and started reservations on this vnode.	*String*. Syntax: *resources_assigned.<resource name>=<value>[,resources_assigned.<resource name>=<value>*			No default	pbs.pbs_resource Syntax: *resources_assigned['<resource name>'] = <val>* where *resource name* is any built-in or custom resource	r	r	r
resources_available The list of resources and the amounts available on this vnode. If not explicitly set, the amount shown is that reported by the `pbs_mom` running on this vnode. If a resource value is explicitly set, that value is retained across restarts.	*String*. Syntax: *resources_available.<resource name>=<value>, resources_available.<resource name> = <value>, ...*			No default	pbs.pbs_resource Syntax: *resources_available['<resource name>'] = <val>* where *resource name* is any built-in or custom resource	r	r, w	r, w

Vnode Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
resv List of advance and standing reservations pending on this vnode.	*String*. Comma-separated list of reservation IDs. Syntax: *<reservation ID>[, <reservation ID>, ...]*			No default	str	r	r	r
resv_enable Controls whether the vnode can be used for advance and standing reservations. Reservations are incompatible with cycle harvesting.	*Boolean*		When set to *True*, this vnode can be used for reservations. Existing reservations are honored when this attribute is changed from *True* to *False*.	*True*	bool	r	r	r, w
sharing Specifies whether more than one job at a time can use the resources of the vnode or the vnode's host. Either (1) the vnode or host is allocated exclusively to one job, or (2) the vnode's or host's unused resources are available to other jobs. Can be set in the cgroups hook's configuration file or by using `pbs_mom -s insert`. Behavior of a vnode or host is determined by a combination of the sharing attribute and a job's placement directive, defined as follows:	*String*. Example: `vnodename: sharing=force_excl`	*default_shared*	Defaults to *shared*	*default_shared*	pbs.ND_DEFAULT_SHARED	r	r, w	r, w
		default_excl	Defaults to *exclusive*		pbs.ND_DEFAULT_EXCL			
		default_exclhost	Entire host is assigned to the job unless the job's sharing request specifies otherwise		pbs.ND_DEFAULT_EXCLHOST			
		ignore_excl	Overrides any job *place=excl* setting		pbs.ND_IGNORE_EXCL			
		force_excl	Overrides any job *place=shared* setting		pbs.ND_FORCE_EXCL			
		force_exclhost	The entire host is assigned to the job, regardless of the job's sharing request		pbs.ND_FORCE_EXCLHOST			
		Unset	Defaults to *shared*					

Vnode Attributes

Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr

Behavior of vnode:

Value of sharing	Placement Request (`-lplace=`)				
	Vnode			Host	
	not specified	place=*shared*	place=*excl*	place=*exclhost*	place**!=***exclhost*
not set	shared	shared	exclusive	exclusive	depends on place
default_shared	shared	shared	exclusive	exclusive	depends on place
default_excl	exclusive	shared	exclusive	exclusive	depends on place
default_exclhost	exclusive	shared	exclusive	exclusive	depends on place
ignore_excl	shared	shared	shared	shared	not exclusive
force_excl	exclusive	exclusive	exclusive	exclusive	not exclusive
force_exclhost	exclusive	exclusive	exclusive	exclusive	exclusive

Vnode Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
state Shows or sets the state of the vnode.	*String.* Comma-separated list of one or more states: *<state>[, <state>, ...]*	*busy*	Vnode is reporting load average greater than allowed max. Can combine with *offline*.	No default	int	r	r	r
		down	Node is not responding to queries from the server. Cannot be combined with *free*, *provisioning*			r	r	r
		free	Vnode is up and capable of accepting new job(s). Cannot be combined with other states.			r	r	r
		job-busy	All CPUs on the vnode are allocated to jobs. Can combine with: *offline*, *resv_exclusive*.			r	r	r
		job-exclusive	Entire vnode is exclusively allocated to one job at the job's request. Can combine with *offline*, *resv_exclusive*			r	r	r
		offline	Jobs are not to be assigned to this vnode. Can combine: *busy, job-busy, job-exclusive, resv_exclusive*.			r	r, w	r, w
		provisioning	Vnode is being provisioned. Cannot be combined with any other states.			r	r	r
		resv-exclusive	Running reservation has requested exclusive use of vnode. Can combine with *job-exclusive*, *offline*			r	r	r
		stale	Vnode was previously reported to server, but is no longer reported to server. Cannot combine with *free*, *provisioning*			r	r	r
		state-unknown	The server has never been able to contact the vnode. Either MoM is not running on the vnode, the vnode hardware is down, or there is a network problem.			r	r	r
		unresolvable	The server cannot resolve the name of the vnode.			r	r	r
		wait-provisioning	Vnode needs to be provisioned, but can't: limit reached for concurrent provisioning vnodes. Cannot be combined with other states. See max_concurrent_provision.			r	r	r
topology_info Contains information intended to be used in hooks. Visible in and usable by hooks only.	*XML string*			*Unset*	str	-	-	-

6.11 Job Attributes

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
Account_Name String used for accounting purposes. Can be used for fairshare.	*String*. Can contain any character.			No default	str	r, w	r, w	r, w
accounting_id Accounting ID for tracking accounting data not produced by PBS.	*String*			No default	str	r	r	r
accrue_type Indicates what kind of time the job is accruing.	*Integer*	*0 (initial_time)*	Job is accruing initial time. Can occur when job is blocked by a runjob hook.	2 (eligible_time)	int	-	-	r
		1 (ineligible_time)	Job is accruing ineligible time. Occurs when job or owner has hit limit.					
		2 (eligible_time)	Job is accruing eligible time. Occurs when job is blocked on resources.					
		3 (run_time)	Job is accruing run time. Occurs when job is running.					
alt_id For a few systems, the session ID is insufficient to track which processes belong to the job. Where a different identifier is required, it is recorded in this attribute. If set, it is also recorded in the end-of-job accounting record. On Windows, holds PBS home directory.	*String.* May contain white spaces.			No default	str	r	r	r

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
argument_list Job executable's argument list. Shown if job is submitted with "`-- <executable> [<argument list>]`"	*JSDL-encoded string*. *<jsdl-hpcpa:Argument> <1st arg> </jsdl-hpcpa:Argument>* *<jsdl-hpcpa:Argument> <2nd arg> </jsdl-hpcpa:Argument>* *<jsdl-hpcpa:Argument> <nth arg> </jsdl-hpcpa:Argument>* Example: if arguments are "A B": `<jsdl-hpcpa:Argument>A</jsdl-hpcpa:Argument> <jsdl-hpcpa:Argument>B</jsdl-hpcpa:Argument>`			No default	str	r, w	r, w	r, w
array Indicates whether this is a job array.	*Boolean*		Set to *True* if this is an array job.	*False*	bool	r, s	r	r
array_id Applies only to subjobs. Array identifier of subjob.	*String*			No default	str	r	r	r
array_index Applies only to subjobs. Index number of subjob.	*String*			No default	int	r	r	r
array_indices_remaining Applies only to job arrays. List of indices of subjobs still queued.	*String.* Range or list of ranges, e.g. `500, 552, 596-1000`.			No default	str	r	r	r
array_indices_submitted Applies only to job arrays. Complete list of indices of subjobs given at submission time.	*String*. Given as range, e.g. `1-100`			No default	pbs.range	r, s	r	r

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
array_state_count Applies only to job arrays. Lists number of subjobs in each state.	*String*			No default	pbs.state_count	r	r	r
block Specifies whether `qsub` will wait for the job to complete and return the exit value of the job. For X11 forwarding jobs, and jobs with interactive and/or block attributes set to *True*, the job's exit status is not returned.	*Boolean*			*False*	int	r, s	r	r
Checkpoint Determines when the job will be checkpointed. An $action script is required to checkpoint the job.	*String*	c	Checkpoint at intervals, measured in CPU time, set on job's execution queue. If no interval set at queue, job is not checkpointed.	*u*	pbs.checkpoint	r, w	r, w	r, w
		c = *<minutes of CPU time>*	Checkpoint at intervals of specified number of minutes of job CPU time. This value must be > 0. If interval specified is less than that set on job's execution queue, queue's interval is used. Format: *Integer*					
		w	Checkpoint at intervals, measured in walltime, set on job's execution queue. If no interval set at queue, job is not checkpointed.					
		w = *<minutes of walltime>*	Checkpoint at intervals of the specified number of minutes of job walltime. This value must be greater than zero. If the interval specified is less that that set on job's execution queue, the queue's interval is used. Format: *Integer*					
		n	No checkpointing.					
		s	Checkpoint only when the server is shut down.					
		u	Unset. Defaults to behavior when *interval* argument is set to *s*.					

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
comment Comment about job. Informational only.	*String*			No default	str	r	r, w	r, w
create_resv_from_job When this job is run, immediately creates and confirms a *job-specific start reservation* on the same resources as the job (including resources inherited by the job), and places the job in the job-specific reservation's queue. Sets the job's create_resv_from_job attribute to *True*. Sets the job-specific reservation's reserve_job attribute to the ID of the job from which the reservation was created. The new reservation's duration and start time are the same as the job's walltime and start time. If the job is peer scheduled, the job-specific reservation is created in the pulling complex.	*Boolean*	*False* *True*	Does not create a reservation. Creates the job-specific start reservation.	*False*	bool	r, w	r, w	r, w
ctime Timestamp; time at which the job was created.	*Timestamp.* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.			No default	int	r	r	r

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
depend Specifies inter-job dependencies. No limit on number of dependencies.	*String*. Syntax: *<type>:<job ID>[:<job ID> ...],[<type>:<job ID>[:<job ID> ...] ...]* Must be enclosed in double quotes if it contains commas. Example: "`before:123:456`"	after:<job ID list>	This job may run at any point after all jobs in *job ID list* have started execution.	No default; no dependencies	pbs.depend	r, w	r, w	r, w
		afterok:<job ID list>	This job may run only after all jobs in *job ID list* have terminated with no errors.					
		afternotok:<job ID list>	This job may run only after all jobs in *job ID list* have terminated with errors.					
		afterany:<job ID list>	This job can run after all jobs in *job ID list* have finished execution, with or without errors. This job will not run if a job in the *job ID list* was deleted without ever having been run.					
		before:<job ID list>	Jobs in *job ID list* may start once this job has started.					
		beforeok:<job ID list>	Jobs in *job ID list* may start once this job terminates without errors.					
		beforenotok:<job ID list>	If this job terminates execution with errors, jobs in *job ID list* may begin.					
		beforeany:<job ID list>	Jobs in *job ID list* may begin execution once this job terminates execution, with or without errors.					
		on:<count>	This job may run after *count* dependencies on other jobs have been satisfied. This type is used with one of the *before* types listed. *Count* is an integer greater than *0*.					
egroup If the job is queued, this attribute is set to the group name under which the job is to be run.	*String*			No default	str	-	-	r

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
eligible_time The amount of wall clock wait time a job has accrued while the job is blocked waiting for resources. For a job currently accruing *eligible_time*, if we were to add enough of the right type of resources, the job would start immediately. Viewable via `qstat -f`.	*Duration*			*Zero*	pbs.duration	r	r, w	r, w
Error_Path The final path name for the file containing the job's standard error stream. See the qsub and qalter commands.	*String*. Syntax: *[<hostname>:]<path>*	*<relative path>*	Path is relative to the current working directory of command executing on current host.	Default path is current working directory where `qsub` is run. If the output path is specified, but does not include a filename, the default filename is *<job ID>.ER*. If the path name is not specified, the default filename is *<job name>.e<sequence number>*.	str	r, w	r, w	r, w
		<absolute path>	Path is absolute path on current host where command is executing.					
		<hostname>:<relative path>	Path is relative to user's home directory on specified host.					
		<hostname>:<absolute path>	Path is absolute path on named host.					
		No path	Path is current working directory where `qsub` is executed.					

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
estimated List of estimated values for job. Used to report job's exec_vnode, start_time, and soft_walltime. Can be set in a hook or via `qalter`, but PBS will overwrite the values.	Syntax: *estimated.<resource name>=<value>, estimated.<resource name>=<value>*. *exec_vnode* is a *string*. *soft_walltime* is a *duration*. *start_time* is printed by `qstat` in human-readable *Date* format; *start_time* is output in hooks as seconds since epoch.	*exec_vnode*	The estimated vnodes used by this job.	Unset	pbs.pbs_resource Syntax: *estimated.[<resource name>]=<value>*. *exec_vnode* is a *pbs.exec_vnode*. *soft_walltime* is a *duration*. *start_time* is an *int*.	r	r, w	r, w
		soft_walltime	The estimated soft walltime for this job. Calculated when a job exceeds its soft_walltime resource.	Unset		r	r	r, w
		start_time	The estimated start time for this job.	Unset		r	r, w	r, w
etime Timestamp; time when job became eligible to run, i.e. was enqueued in an execution queue and was in the "*Q*" state. Reset when a job moves queues, or is held then released. Not affected by qaltering.	*Timestamp.* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.			No default	int	r	r	r
euser If the job is queued, this attribute is set to the user name under which the job is to be run.	*String*			No default	str	-	-	r
executable JSDL-encoded listing of job's executable. Shown if job is submitted with "`-- <executable> [<arg list>]`".	*JSDL-encoded string.* *<jsdl-hpcpa:Executable> <name of executable>* Example: if the executable is `ping`: `<jsdl-hpcpa:Executable>ping</jsdl-hpcpa:Executable>`			No default	str	r, w	r, w	r, w

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
Execution_Time Timestamp; time after which the job may execute. Before this time, the job remains queued in the (*W*)ait state. Can be set when stage-in fails and PBS moves job start time out 30 minutes to allow user to fix problem.	*Datetime*. See Chapter 7, "Formats", on page 353.			Unset; no delay	int	r, w	r, w	r, w
exec_host If the job is running, this is set to the name of the host or hosts on which the job is executing.	*String*. Syntax: <*host-name*>/*N*[**C*][+...], where *N* is task slot number starting at 0, on that host, and *C* is the number of CPUs allocated to the job. **C* does not appear if its value is *1*.			No default	pbs.exec_host	r	r, i	r, i
exec_vnode List of chunks for the job. Each chunk shows the name of the vnode(s) from which it is taken, along with the host-level, consumable resources allocated from that vnode, and any AOE provisioned on this vnode for this job. If a vnode is allocated to the job but no resources from the vnode are used by the job, the vnode name appears alone. If a chunk is split across vnodes, the name of each vnode and its resources appear inside one pair of parentheses, joined with a plus ("+") sign.	Each chunk is enclosed in parentheses. Chunks are connected by plus signs. Example: For a job which requested two chunks satisfied by resources from three vnodes, exec_vnode is: `(vnodeA:ncpus=N:mem=X)+(nodeB:ncpus=P:mem=Y+nodeC:mem=Z)`. For a job which requested one chunk and exclusive use of a 2-vnode host, where the chunk was satisfied by resources from one vnode, exec_vnode is `(vnodeA:ncpus=N:mem=X)+(vnodeB)`.			No default	pbs.exec_vnode	r	r, w	r, w

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
Exit_status Exit status of job. Set to zero for successful execution. If any subjob of an array job has non-zero exit status, the array job has non-zero exit status.	*Integer*			No default	int	r	r	r
forward_x11_cookie Contains the X authorization cookie.	*String*			No default	str	r	r	r
forward_x11_port Contains the number of the port being listened to by the port forwarder on the submission host.	*Integer*			No default	int	r	r	r
group_list A list of group names used to determine the group under which the job runs. When a job runs, the server selects a group name from the list according to the following ordered set of rules: 1. Select the group name for which the associated host name matches the name of the server host. 2. Select the group name which has no associated host name. 3. Use the login group for the user name under which the job will be run.	*String*. Syntax: *<group name>[@<host-name>] [,<group name>[@<host-name>]...]* Must be enclosed in double quotes if it contains commas.			No default	pbs.group_list	r, w	r, w	r, w
hashname No longer used.						-	-	-
Hold_Types The set of holds currently applied to the job. If the set is not null, the job will not be scheduled for execution and is said to be in the *held* state. The *held* state takes precedence over the *wait* state.	*String*, made up of the letters 'n', 'o', 'p', 's', 'u'	*n*	No hold	*n*	pbs.hold_types	r, w	r, w	r, w
		o	Other hold					
		p	Bad password					
		s	System hold					
		u	User hold					

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
interactive Specifies whether the job is interactive. Can be set, but not altered, by unprivileged user. When both this attribute and the block attribute are *True*, no exit status is returned. For X11 forwarding jobs, the job's exit status is not returned. Cannot be set using a PBS directive. Job arrays cannot be interactive.	*Boolean*		Set to *True* if this is an interactive job.	*False*	int	r, w	r	r
jobdir Path of the job's staging and execution directory on the primary execution host. Either user's home, or private sandbox. Depends on value of sandbox attribute. Viewable via `qstat -f`.	*String*			No default	str	r	r	r
Job_Name The job name. See the `qalter` and `qsub` commands.	*String* up to 236 characters, first character must be alphabetic or numeric			Base name of job script, or STDIN	str	r, w	r, w	r, w
Job_Owner The login name on the submitting host of the user who submitted the batch job.	*String.* Syntax: *<Username>@<submission host>*			No default	str	r	r	r

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
job_state The state of the job.	*Character*	*B (Begun)*	Job arrays only. Job array has begun execution.	No default	pbs.JOB_STATE_BEGUN	r, i	r, i	r, i
		E (Exiting)	The job has finished, with or without errors, and PBS is cleaning up post-execution.		pbs.JOB_STATE_EXITING			
		F (Finished)	Job is finished. Job has completed execution, job failed during execution, or job was deleted.		pbs.JOB_STATE_FINISHED			
		H (Held)	The job is held.		pbs.JOB_STATE_HELD			
		M (Moved)	The job has been moved to another server.		pbs.JOB_STATE_MOVED			
		Q (Queued)	The job resides in an execution or routing queue pending execution or routing. It is not in held or waiting state.		pbs.JOB_STATE_QUEUED			
		R (Running)	The job is in an execution queue and is running.		pbs.JOB_STATE_RUNNING			
		S (Suspended)	The job was executing and has been suspended. The job does not use CPU cycles or walltime.		pbs.JOB_STATE_SUSPEND			
		T (Transiting)	The job is being routed or moved to a new destination.		pbs.JOB_STATE_TRANSIT			
		U (User suspended)	The job was running on a workstation configured for cycle harvesting and the keyboard/mouse is currently busy. The job is suspended until the workstation has been idle for a configured amount of time.		pbs.JOB_STATE_SUSPEND_USERACTIVE			
		W (Waiting)	The Execution_Time attribute contains a time in the future. Can be set when stage-in fails and PBS moves job start time out 30 minutes to allow user to fix problem.		pbs.JOB_STATE_WAITING			
		X (Expired)	Subjobs only. Subjob is finished (expired.)		pbs.JOB_STATE_EXPIRED			

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
Join_Path Specifies whether the job's standard error and standard output streams are to be merged and placed in the file specified in the Output_Path job attribute.	*String* One of "*oe*", "*eo*", or "*n*".	*eo*	Standard output and standard error are merged, intermixed, into a single stream, which becomes standard error.	*n*	pbs.join_path	r, w	r, w	r, w
		oe	Standard output and standard error are merged, intermixed, into a single stream, which becomes standard output.					
		n	Standard output and standard error are not merged.					
Keep_Files Specifies whether the standard output and/or standard error streams are retained on the execution host in the job's staging and execution directory after the job has executed. Otherwise these files are returned to the submission host. Keep_Files overrides the Output_Path and Error_Path attributes.	*String* One of "*o*", "*e*", "*oe*", "*eo*", or "*n*".	*o*	The standard output stream is retained. The filename is: *<job name>.o<sequence number>*	*n*	pbs.keep_files	r, w	r, w	r, w
		e	The standard error stream is retained. The filename is: *<job name>.e<sequence number>*					
		eo, oe	Both standard output and standard error streams are retained.					
		d	Output and error are written directly to their final destination					
		n	Neither stream is retained. Files are returned to submission host.					
Mail_Points Specifies state changes for which the server sends mail about the job.	*String* Can be any of "*a*", "*b*", "*e*", with optional "*j*", or "*n*".	*a*	Mail is sent when job is aborted	*a*	pbs.mail_points	r, w	r, w	r, w
		b	Mail is sent at beginning of job					
		e	Mail is sent at end of job					
		j	Mail is sent for subjobs. Must be combined with one or more of a, b, and e options					
		n	No mail is sent. Cannot be combined with other options.					
Mail_Users The set of users to whom mail is sent when the job makes state changes specified in the Mail_Points job attribute.	*String* Syntax: *"<username>@<hostname>[,<username>@<hostname>]"* Must be enclosed in double quotes if it contains commas.			Job owner only	pbs.email_list	r, w	r, w	r, w

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
max_run_subjobs Sets a limit on the number of subjobs that can be running at one time. Can be set using `qsub -J <range> [%<max subjobs>]` or `qalter -Wmax_run_subjobs=<new value> <job ID>`. Suspended subjobs are not counted against this limit.	*Integer*			No default	int	r, w	r, w	r, w
mtime Timestamp; the time that the job was last modified, changed state, or changed locations.	*Timestamp.* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.			No default	int	r	r	r
no_stdio_sockets Not used.						-	-	-
obittime Time when job or subjob obit was sent	*Integer* *Seconds since epoch*			No default	int	r	r	r

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
Output_Path The final path name for the file containing the job's standard output stream. See the `qsub` and `qalter` commands.	*String*. Syntax: *[<hostname>:]<path>*	*<relative path>*	Path is relative to the current working directory of command executing on current host.	Default path is current working directory where `qsub` is run. If the output path is specified, but does not include a filename, the default filename is *<job ID>.OU*. If the path name is not specified, the default filename is *<job name>.o<sequence number>*.	str	r, w	r, w	r, w
		<absolute path>	Path is absolute path on current host where command is executing.					
		<hostname>:<relative path>	Path is relative to user's home directory on specified host.					
		<hostname>:<absolute path>	Path is absolute path on named host.					
		No path	Path is current working directory where `qsub` is executed.					
pcap_accelerator Power attribute. Power cap for an accelerator. Corresponds to Cray `capmc set_power_cap --accel` setting. See `capmc` documentation.	*Integer* Units*: Watts*			Unset	int	r, w	r, w	r, w
pcap_node Power attribute. Power cap for a node. Corresponds to Cray `capmc set_power_cap --node` setting. See `capmc` documentation.	*Integer* Units*: Watts*			Unset	int	r, w	r, w	r, w
pgov Power attribute. Cray ALPS reservation setting for CPU throttling corresponding to p-governor. See BASIL 1.4 documentation. We do not recommend using this attribute.	*String*			Unset	str	r, w	r, w	r, w

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
Priority The scheduling priority for the job. Higher value indicates greater priority.	*Integer*. Syntax: *[+|-]nnnn*	*[-1024, +1023]* inclusive		Unset	int	r, w	r, w	r, w
project The job's project. A project is a way to tag jobs. Each job can belong to at most one project.	*String*. Can contain any characters except for the following: Slash ("/"), left bracket ("["), right bracket ("]"), double quote (""""), semicolon (";"), colon (":"), vertical bar ("|"), left angle bracket ("<"), right angle bracket (">"), plus ("+"), comma (","), question mark ("?"), and asterisk ("*").			*_pbs_project_default*	str	r, w	r, w	r, w
pstate Power attribute. Cray ALPS reservation setting for CPU frequency corresponding to p-state. See BASIL 1.4 documentation.	*String* Units: *Hertz*			Unset	str	r, w	r, w	r, w
qtime Timestamp; the time that the job entered the current queue.	*Timestamp.* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.			No default	int	r	r	r
queue The name of the queue in which the job currently resides.	*String*			No default	pbs.queue	r	r	r
queue_rank A number indicating the job's position within its queue. Only used internally by PBS.	*Integer*			No default	int	-	-	r

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
queue_type The type of queue in which the job is currently residing.	*Character*	*E*	Execution queue	No default	pbs.QTYPE_EXECUTION	-	-	r
		R	Routing queue		pbs.QTYPE_ROUTE			
release_nodes_on_stageout Controls whether job vnodes are released when stageout begins. When cgroups is enabled and this is used with some but not all vnodes from one MoM, resources on those vnodes that are part of a cgroup are not released until the entire cgroup is released. The job's stageout attribute must be set for the release_nodes_on_stageout attribute to take effect.	*Boolean*	*True*	All of the job's vnodes not on the primary execution host are released when stageout begins	*False*	bool	r, w	r, w	r, w
		False	Job's vnodes are released when the job finishes and MoM cleans up the job					
Remove_Files Specifies whether standard output and/or standard error files are automatically removed upon job completion.	*String*	*e*	Standard error is removed upon job completion	Unset	str	r, w	r, w	r, w
		o	Standard output is removed upon job completion					
		eo	Standard output and standard error are removed upon job completion					
		oe	Standard output and standard error are removed upon job completion					
		unset	Neither is removed					
Rerunable Specifies whether the job can be rerun. Does not affect how a job is treated if the job could not begin execution. See "Allowing Your Job to be Re-run", on page 120 of the PBS Professional User's Guide. Job arrays are required to be rerunnable and are rerunnable by default.	*Character*	*y*	The job can be rerun.	*y*	bool	r, w	r, w	r, w
		n	Once the job starts running, it can never be rerun.					

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
Resource_List The list of resources required by the job. List is a set of <*resource name*>=<*value*> strings. The meaning of name and value is dependent upon defined resources. Each value establishes the limit of usage of that resource. If not set, the value for a resource may be determined by a queue or server default established by the administrator. See Chapter 5, "List of Built-in Resources", on page 259.	*String.* Syntax: *Resource_List.<resource name>=<value>], Resource_List.<resource name>=<value>, ...]*			No default	pbs.pbs_resource Syntax: *Resource_List["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r, w	r, w	r, w
resources_released Listed by vnode, consumable resources that were released when the job was suspended. Populated only when restrict_res_to_release_on_suspend server attribute is set. Set by server.	*String.* Syntax: *(<vnode>:<resource name>=<value>:<resource name>=<value>:...)+(<vnode>:<resource name>=<value>:...)*			No default	str	r	r	r
resource_released_list Sum of each consumable resource requested by the job that was released when the job was suspended. Populated only when restrict_res_to_release_on_suspend server attribute is set. Set by server.	*String.* Syntax: *resource_released_list.<resource name>=<value>,resource_released_list.<resource name>=<value>, ...*			No default	pbs.pbs_resource	--	r	r
resources_used The amount of each resource used by the job.	*String.* Syntax: List of *resources_used.<resource name>=<value>,resources_used.<resource name>=<value>* pairs. Example: `resources_used.mem=2mb`			No default	pbs.pbs_resource Syntax: *resources_used["<resource name>"]=<value>* where *resource name* is any built-in or custom resource	r	r	r

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
run_count The number of times the server thinks the job or subjob has been executed. The run_count attribute starts at zero. Job is held after 21 tries. When a subjob hits the run_count limit, it and its parent job array get a System hold. Can be set via `qsub`, `qalter`, or a hook.	*Integer.* Must be greater than or equal to *zero*.			*Zero*	int	-	r, w	r, w
run_version Used internally by PBS to track the instance of the job.	*Integer*				int	--	--	r
sandbox Specifies whether PBS creates job-specific staging and execution directories. User-settable via `qsub -Wsandbox=<value>` or via a PBS directive. See the $jobdir_root MoM configuration option.	*String*	*PRIVATE*	PBS creates job-specific staging and execution directories under the directory specified in the $jobdir_root MoM configuration option or under the submitter's home directory.	Unset	str	r, w	r, w	r, w
		HOME or unset	PBS uses the job owner's home directory for staging and execution.					
schedselect The union of the select specification of the job, and the queue and server defaults for resources in a chunk.	*String*			No default	pbs.select	-	-	r
sched_hint No longer used.						-	-	-
security_context Contains security context of job submitter. Set by PBS to the security context of the job submitter at the time of job submission. If not present when a request is submitted, an error occurs, a server message is logged, and the request is rejected.	*String in SELinux format*			Unset	str	r	r	r

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
server The name of the server which is currently managing the job. When the secondary server is running during failover, shows the name of the primary server. After a job is moved to another server, either via `qmove` or peer scheduling, shows the name of the new server.	*String*			No default	pbs.server	r	r	r
session_id If the job is running, this is set to the session ID of the first executing task.				No default	int	r	r	r
Shell_Path_List One or more absolute paths to the program(s) to process the job's script file.	*String*. Syntax: *"<path>[@<hostname>][,<path>[@<hostname>]...]"* Must be enclosed in double quotes if it contains commas.			User's login shell on execution host	pbs.path_list	r, w	r, w	r, w
stagein The list of files to be staged in prior to job execution.	*String*. Syntax: *"<execution path>@<storage host>:<storage path>[, <execution path>@<storage host>:<storage path>, ...]"* Must be enclosed in double quotes if it contains commas.			No default	pbs.staging_list	r, w	r, w	r, w
stageout The list of files to be staged out after job execution.	*String*. Syntax: *"<execution path>@<storage host>:<storage path>[, <execution path>@<storage host>:<storage path>, ...]"* Must be enclosed in double quotes if it contains commas.			No default	pbs.staging_list	r, w	r, w	r, w

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
Stageout_status Status of stageout. If stageout succeeded, this is set to *1*. If stageout failed, this is set to *0*. Available only for finished jobs. Displayed only if set. If stageout fails for any subjob of an array job, the value of Stageout_status is zero for the array job. Available only for finished jobs.	*Integer*			No default	int	r	r	r
stime Timestamp; time when the job started execution. Changes when job is restarted.	*Timestamp.* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.			No default	int	r	r	r
Submit_arguments Job submission arguments given on the `qsub` command line. Available for all jobs.	*String*			No default	str	r, w	r, w	r, w
substate The substate of the job. The substate is used internally by PBS.	*Integer*			No default	int	r	r	r
sw_index No longer used.						-	-	-

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
tolerate_node_failures Specifies whether job can have extra vnodes allocated, and whether for startup only or for the life of the job. Not supported on Cray.	*String*	*none, unset*	No extra vnodes are allocated to the job.	None	str	r, s	r, s	r, s
		job_start	Extra vnodes are allocated only long enough to start the job successfully. Tolerate vnode failures that occur only during job start, just before executing the job's top level shell or executable or any execjob_launch hooks. Failures tolerated are those such as an assigned sister MoM failing to join the job and communication errors between MoMs.					
		all	Extra vnodes are allocated for the life of the job. Tolerate all node failures resulting from communication problems, such as polling problems, between the primary MoM and the sister MoMs assigned to the job Tolerate failures due to rejections from execjob_begin or execjob_prologue hooks run at sister MoMs.					
topjob_ineligible Allows administrators to mark this job as ineligible to be a top job.	*Boolean*	*True*	This job is not eligible to be a top job.	*Unset*, behaves like *False*	bool	-	-	r, w
		False	This job is eligible to be a top job.					
umask The initial `umask` of the job is set to the value of this attribute when the job is created. The `umask` may be changed by `umask` commands in the shell initialization files such as `.profile` or `.cshrc`.	*Decimal integer*			*system default*	int	r, w	r, w	r, w

Job Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Def Val	Python Type	Usr	Opr	Mgr
User_List The list of users which determines the user name under which the job is run on a given host. No length limit. When a job is to be executed, the server selects a user name from the list according to the following ordered set of rules: 1. Select the user name from the list for which the associated host name matches the name of the server. 2. Select the user name which has no associated host name; the wild card name. 3. Use the value of Job_Owner as the user name.	*String*. Syntax: *"<username>@<hostname> [,<username>@<hostname>...]"* Must be enclosed in double quotes if it contains commas. May be up to 256 characters in length.			Value of Job_Owner job attribute	pbs.user_list	r, w	r, w	r, w
Variable_List List of environment variables set in the job's execution environment. See the `qsub(1B)` command.	*String*. Syntax: *"<variable name>=<value> [,<variable name>=<value>...]"* Must be enclosed in double quotes if it contains commas.			No default	pbs.pbs_resource Syntax: *Variable_List["<variable name>"]=<value>*	r, w	r, w	r, w

6.12 Hook Attributes

An unset hook attribute takes the default value for that attribute.

Hook attributes can be set by root or the Admin at the local server only.

Hook Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	Usr	Opr	Mgr
alarm Specifies the number of seconds to allow a hook to run before the hook times out.	*Integer.* Must be greater than *zero*.			*30*				
debug Specifies whether or not the hook produces debugging files under `PBS_HOME/server_priv/hooks/tmp` or `PBS_HOME/mom_priv/hooks/tmp`. Files are named *hook_<hook event>_<hook name>_<unique ID>.in*, *.data*, and *.out*. See "Producing Files for Debugging" on page 183 in the PBS Professional Hooks Guide.	*Boolean*	*True*	The hook leaves debugging files when it runs.	*False*				
		False	The hook does not leave debugging files when it runs.					
enabled Determines whether or not a hook is run when its triggering event occurs.	*Boolean*	*True*	Hook runs when triggering event occurs.	*True*				
		False	Hook does not run when triggering event occurs.					

Hook Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	Usr	Opr	Mgr
event List of events that trigger the hook. Can be operated on with the "=", "+=", and "-=" operators. The *provision* event cannot be combined with any other events.	*String_array*	*"queuejob"*	Triggered before job is queued	"" meaning hook is not triggered	str			
		"postqueuejob"	Triggered after job is queued					
		"modifyjob"	Triggered when job is modified					
		"movejob"	Triggered when job is moved					
		"runjob"	Triggered when job is run					
		"jobobit"	Triggered when job or subjob leaves execution					
		"resvsub"	Triggered when reservation is created					
		"resv_confirm"	Triggered when reservation is confirmed					
		"modifyresv"	Triggered when reservation is modified					
		"resv_begin	Triggered when reservation begins					
		"resv_end"	Triggered when reservation ends					
		"management"	Triggered by `qmgr` operations					
		"modifyvnode"	Triggered by vnode state change					
		"periodic"	Triggered periodically at server					
		"provision"	Hook is master provisioning hook					
		"execjob_begin"	Triggered when MoM receives job					
		"execjob_prologue"	Triggered just before first job process					
		"execjob_launch"	Triggered just before executing user's program					
		"execjob_attach"	Triggered before any execjob_prologue hooks, on each vnode where `pbs_attach()` runs					
		execjob_postsuspend	Triggered just after successfully suspending a job					
		execjob_preresume	Triggered just before resuming a job					
		"execjob_preterm"	Triggered just before job is killed					
		"execjob_epilogue"	Triggered after job runs successfully or is killed					
		"execjob_end"	Triggered just after job is cleaned up					
		"exechost_periodic"	Triggered at periodic interval on execution hosts					
		"exechost_startup"	Triggered when MoM starts up or receives SIGHUP (Linux)					
		""	Hook is not triggered					

Hook Attributes								
Name Description	Format	Val / Opt	Value/Option Description	Default Value	Python Type	Usr	Opr	Mgr
fail_action Specifies the action to be taken when hook fails due to alarm call or unhandled exception, or to an internal error such as not enough disk space or memory. Can also specify a subsequent action to be taken when hook runs successfully. Value can be either "*none*" or one or more of "*offline_vnodes*", "*clear_vnodes_upon_recovery*", and "*scheduler_restart_cycle*". If this attribute is set to multiple values, scheduler restart happens last. See "Offlining and Clearing Vnodes Using the fail_action Hook Attribute" on page 72 in the PBS Professional Hooks Guide and "Restarting Scheduler Cycle After Hook Failure" on page 69 in the PBS Professional Hooks Guide.	*String_array*	*"none"*	No action is taken.	*"none"*				
		"offline_vnodes"	After unsuccessful hook execution, offlines the vnodes managed by the MoM executing the hook. Only available for execjob_prologue, exechost_startup and execjob_begin hooks.					
		"clear_vnodes_upon_recovery"	After successful hook execution, clears vnodes previously offlined via *"offline_vnodes"* fail action. Only available for exechost_startup hooks.					
		"scheduler_restart_cycle"	After unsuccessful hook execution, restarts scheduling cycle. Only available for execjob_begin and execjob_prologue hooks.					
freq Number of seconds between periodic or exechost_periodic triggers.	*Integer*		Number of seconds between triggers	*120*				
order Indicates relative order of hook execution, for hooks of the same type sharing a trigger. Hooks with lower order values execute before those with higher values. Does not apply to periodic or exechost_periodic hooks.	*Integer*	*Range:* *built-in hooks: [-1000, 2000]* *site hooks: [1,1000]*		*1*				
type The type of the hook. Cannot be set for a built-in hook.	*String*	*pbs*	Hook is built in	*site*				
		site	Hook is custom (site-defined)					
user Specifies who executes the hook.	*String*	*pbsadmin*	Hook runs as root	*pbsadmin*				
		pbsuser	Hook runs as owner of job					

7 Formats

This chapter describes the formats used in PBS Professional.

7.1 Non-resource Formats

Accounting Log Entry

logfile-date-time;record-type;id-string;message-text

where

logfile-date-time

Date and time stamp in the format:

mm/dd/yyyy hh:mm:ss

record-type

A single character indicating the type of record

id-string

The job or reservation identifier

message-text

Format: blank-separated *keyword=value* fields.

Message text is ASCII text.

Content depends on the record type.

Attribute Name

PBS NAME. Cannot be used for a vnode name.

Date

<Day of week> <Name of month> <Day of month> <HH:MM:SS> <YYYY>

Datetime

A datetime is

[[[[CC]YY]MM]DD]hhmm[.SS]

where

Table 7-1: Datetime Symbols

Symbol	Meaning
CC	Century
YY	Year
MM	Month
DD	Day of month
hh	Hour
mm	Minute
SS	Second

When setting the value, each portion of the date defaults to the current date, as long as the next-smaller portion is in the future. For example, if today is the 3rd of the month and the specified day DD is the 5th, the month MM will be set to the current month.

If a specified portion has already passed, the next-larger portion will be set to one after the current date. For example, if the day DD is not specified, but the hour hh is specified to be 10:00 a.m. and the current time is 11:00 a.m., the day DD will be set to tomorrow.

Destination Identifier

String used to specify a particular destination. The identifier may be specified in one of three forms:

<queue name>@<server name>

<queue name>

@<server name>

where *<queue name>* is an ASCII character string of up to 15 characters.

Valid characters are alphanumerics, the hyphen and the underscore. The string must begin with a letter.

Hostname

String of the form

<machine name>.<domain name>

where *domain name* is a hierarchical, dot-separated list of subdomains.

A hostname cannot contain the following:

- A dot ("."), other than as a subdomain separator
- The commercial at sign, "@", as this is often used to separate a file from the host in a remote file name
- To prevent confusion with port numbers, a hostname cannot contain a colon (":")

The maximum length of a hostname supported by PBS is *255*.

Job Array ID, Job Array Identifier

The identifier returned upon success when submitting a job array.

Job array identifiers are a sequence number followed by square brackets:

<sequence number>[][.<server name>][@<server name>]

Example:

```
1234[]
```

Note that some shells require that you enclose a job array ID in double quotes.

The largest value that *sequence number* can be is set in the max_job_sequence_id server attribute. This attribute defaults to *9999999*. Minimum value for this attribute is *9999999*, and maximum is *999999999999*. After maximum for sequence number has been reached, job array IDs start again at *0*.

Job Array Range

<sequence number>[<first>-<last>][.<server name>][@<server name>]

first and *last* are the first and last indices of the subjobs.

Job ID, Job Identifier

When a job is successfully submitted to PBS, PBS returns a unique identifier for the job. Format:

<sequence number>[.<server>][@<new server>]

The <server> portion indicates the name of the original server where the job was submitted.

The @<new server> portion indicates the current location of the job if it is not at the original server.

The largest value that *sequence number* can be is set in the max_job_sequence_id server attribute. This attribute defaults to *9999999*. Minimum value for this attribute is *9999999*, and maximum is *999999999999*. After maximum for sequence number has been reached, job IDs start again at *0*.

Job Name, Job Array Name

A job name or job array name can be at most 230 characters. It must consist only of alphabetic, numeric, plus sign ("+"), dash or minus or hyphen ("-"), underscore ("_"), and dot or period (".") characters.

Default: if a script is used to submit the job, the job's name is the name of the script. If no script is used, the job's name is "*STDIN*".

Limit Specification

<limit specification>=<limit value>[, <limit specification>=<limit value>, ...]

where *limit specification* is:

Table 7-2: Limit Specification Syntax

Limit Specification	Limit
o:PBS_ALL	Overall limit
u:PBS_GENERIC	Generic users
u:<username>	An individual user
g:PBS_GENERIC	Generic groups
g:<group name>	An individual group
p:PBS_GENERIC	Generic projects
p:<project name>	An individual project

- The *limit specification* can contain spaces anywhere except after the colon (":").
- If there are comma-separated *limit specifications*, the entire string must be enclosed in double quotes.
- A username, group name, or project name containing spaces must be enclosed in quotes.
- If a username, group name, or project name is quoted using double quotes, and the entire string requires quotes, the outer enclosing quotes must be single quotes. Similarly, if the inner quotes are single quotes, the outer quotes must be double quotes.
- *PBS_ALL* is a keyword which indicates that this limit applies to the usage total.
- *PBS_GENERIC* is a keyword which indicates that this limit applies to generic users, groups, or projects.
- When removing a limit, the *limit value* does not need to be specified.
- *PBS_ALL* and *PBS_GENERIC* are case-sensitive.

Format for setting a limit attribute:

set server <limit attribute> = "<limit specification>=<limit value>[, <limit specification>=<limit value>], ..."

set queue <queue name> <limit attribute> = "<limit specification>=<limit value>[, <limit specification>=<limit value>], ..."

For example, to set the max_queued limit on QueueA to *5* for total usage, and to limit user bill to *3*:

```
Qmgr: s q QueueA max_queued = "[o:PBS_ALL=5], [u:bill =3]"
```

Examples of setting, adding, and removing:

```
Qmgr: set server max_run="[u:PBS_GENERIC=2], [g:group1=10], [o:PBS_ALL = 100]"
Qmgr: set server max_run+="[u:user1=3], [g:PBS_GENERIC=8]"
Qmgr: set server max_run-="[u:user2], [g:group3]"
Qmgr: set server max_run_res.ncpus="[u:PBS_GENERIC=2], [g:group1=8], [o:PBS_ALL = 64]"
```

See "How to Set Limits at Server and Queues" on page 292 in the PBS Professional Administrator's Guide.

Event logfile-date-time

Date and time stamp in the format:

mm/dd/yyyy hh:mm:ss[.xxxxxx]

If microsecond logging is enabled, microseconds are logged using the *.xxxxxx* portion. Microseconds may be preceded by zeroes. Microsecond logging is controlled per host via the PBS_LOG_HIGHRES_TIMESTAMP configuration parameter or environment variable.

pathname

All printable characters except for ampersand ("&")

PBS NAME

"PBS NAME" is a generic term, used to describe various PBS entities. For example, attribute names are PBS NAMEs.

Must start with an alphabetic character, and may contain only the following: alpha-numeric, underscore ("_"), or dash ("-").

Do not use PBS keywords as PBS NAMEs.

PBS Password

The `pbs_ds_password` command generates passwords containing the following characters:

0123456789abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ!@#$%^&()_+*

When creating a password manually, do not use \ (backslash) or ‘ (backquote). This can prevent certain commands such as `pbs_server`, `pbs_ds_password`, and `printjob` from functioning properly, as they rely on connecting to the database.

Project Name

A project name can contain any characters except for the following: slash ("/"), left bracket ("["), right bracket ("]"), double quote (""""), semicolon (";"), colon (":"), vertical bar ("|"), left angle bracket ("<"), right angle bracket (">"), plus ("+"), comma (","), question mark ("?"), and asterisk ("*").

Default value: "*_pbs_project_default*".

Queue ID, Queue Identifier

To specify a queue at the default server:

<queue name>

To specify all queues at a server:

@<server name>

To specify a queue at a specific server:

<queue name>@<server name>

Queue Name

PBS NAME up to 15 characters in length

Reservation ID, Reservation Identifier

Format for an advance reservation:

R<sequence number>[.<server name>][@<server name>]

Format for a standing reservation:

S<sequence number>[.<server name>][@<server name>]

Format for a maintenance reservation:

M<sequence number>[.<server name>][@<server name>]

The largest value that *sequence number* can be is set in the max_job_sequence_id server attribute. This attribute defaults to *9999999*. Minimum value for this attribute is *9999999*, and maximum is *999999999999*. After maximum for sequence number has been reached, reservation IDs start again at *0*.

Reservation Name

Same as Job Name. See "Job Name, Job Array Name" on page 355.

Resource Name

PBS NAME up to 64 characters in length

Resource names are case-sensitive.

Subjob Identifier

Subjob identifiers are a sequence number followed by square brackets enclosing the subjob's index:

<sequence number>[<index>][.<server name>][@<server name>]

Example:

```
1234[99]
```

Timestamp

Output format varies depending on context:

- Printed by `qstat` in human-readable *Date* format
- Output in hooks as seconds since epoch

Username

Linux username:

String up to 256 characters in length. PBS supports usernames containing any printable, non-whitespace character except the at sign ("@"). Your platform may place additional limitations on usernames.

Windows username:

Must conform to the POSIX-1 standard for portability:

- The username must contain only alphanumeric characters, dot (.), underscore (_), and/or hyphen "-".
- The hyphen must not be the first letter of the username.
- If "@" appears in the username, it will assumed to be in the context of a Windows domain account: username@domainname.

An exception to the above rule is the space character, which is allowed. If a space character appears in a username string, it will be displayed quoted and must be specified in a quoted manner.

Vnode Name

Hostname, IP address, or other legal string, according to the following:

- For the parent vnode, the vnode name must conform to legal name for a host; see Hostname
- For other vnodes, the vnode name can be alphanumeric and any of these:

  - (dash)

  _ (underscore)

  @ (at sign)

  [(left bracket)

  ] (right bracket)

  # (hash)

  ^ (caret)

  / (slash)

  \ (backslash)

. (period)

- Cannot be the same as an attribute name
- Vnode names are case-insensitive

7.2 Resource Formats

Boolean

Name of Boolean resource is a string.

Values:

TRUE, True, true, T, t, Y, y, 1

FALSE, False, false, F, f, N, n, 0

Duration

A period of time, expressed either as

An integer whose units are seconds

or

[[hours:]minutes:]seconds[.milliseconds]

in the form:

[[[HH]HH:]MM:]SS[.milliseconds]

Milliseconds are rounded to the nearest second.

Float

Floating point. Allowable values: [+-] 0-9 [[0-9] ...][.][[0-9] ...]

Long

Long integer. Allowable values: 0-9 [[0-9] ...], and + and -

<queue name>@<server name>

Size

Number of bytes or words. The size of a word is 64 bits.

Format: *<integer>[<suffix>]*

where *suffix* can be one of the following:

Table 7-3: Size in Bytes

Suffix	Meaning	Size
b or w	Bytes or words	1
kb or kw	Kilobytes or kilowords	2 to the 10th, or 1024
mb or mw	Megabytes or megawords	2 to the 20th, or 1,048,576
gb or gw	Gigabytes or gigawords	2 to the 30th, or 1,073,741,824
tb or tw	Terabytes or terawords	2 to the 40th, or 1024 gigabytes
pb or pw	Petabytes or petawords	2 to the 50th, or 1,048,576 gigabytes

Default: *bytes*

Note that a scheduler rounds all resources of type size up to the nearest kb.

String

Any character, including the space character.

Only one of the two types of quote characters, " or ', may appear in any given value.

Values:[_a-zA-Z0-9][[-_a-zA-Z0-9 ! " # $ % ´ ( ) * + , - . / : ; < = > ? @ [\ ] ^ _ ' { | } ~] ...]

String resource values are case-sensitive. No limit on length.

String Array

Comma-separated list of strings.

Strings in string_array may not contain commas. No limit on length.

Python type is *str*.

A string array resource with one value works exactly like a string resource.

8 States

This chapter lists and describes the states in PBS Professional.

8.1 Job States

Job states are abbreviated to one character.

Table 8-1: Job States

State	Numeric	Description
B	*7*	Job arrays only: job array is begun, meaning that at least one subjob has started
E	*5*	Job is exiting after having run
F	*9*	Job is finished. Job has completed execution, job failed during execution, or job was deleted.
H	*2*	Job is held. A job is put into a held state by the server or by a user or administrator. A job stays in a held state until it is released by a user or administrator.
M	*8*	Job was moved to another server
Q	*1*	Job is queued, eligible to run or be routed
R	*4*	Job is running
S	*400*	Job is suspended by scheduler. A job is put into the suspended state when a higher priority job needs the resources.
T	*0*	Job is in transition to or from a server
U	*410*	Job is suspended due to workstation becoming busy
W	*3*	Job is waiting for its requested execution time to be reached, or job is delayed due to stagein failure.
X	*6*	Subjobs only; subjob is finished (expired.)

8.1.1 Job Substates

Job substates are numeric:

Table 8-2: Job Substates

Substate Number	Substate Description
00	Transit in, prior to waiting for commit
01	Transit in, waiting for commit
02	transiting job outbound, not ready to commit

Table 8-2: Job Substates

Substate Number	Substate Description
03	transiting outbound, ready to commit
10	Job queued and ready for scheduling
11	job queued, has files to stage in
13	Job waiting on sync start ready
14	job staging in files before waiting
15	job staging in files before running
16	job stage in complete
20	job held - user or operator
21	job held waiting on sync regist
22	job held - waiting on dependency
30	Job waiting until user-specified execution time
37	job held - file stage in failed
41	job sent to MoM to run
42	Running
43	Suspended by Operator or Manager
45	Suspended by scheduler
50	Server received job obit
51	Staging out stdout/err and other files
52	Deleting stdout/err files and staged-in files
53	MoM releasing resources
54	Job is being aborted by server
56	(Set by MoM) Mother Superior telling sisters to kill everything
57	(Set by MoM) job epilogue running
58	(Set by MoM) job obit notice sent
59	Waiting for site-defined job termination action script
60	Job to be rerun, MoM sending stdout/stderr back to server
61	Job to be rerun, staging out files
62	Job to be rerun, deleting files
63	Job to be rerun, freeing resources
69	subjob is gone
70	Array job has begun
71	Job is waiting for vnode(s) to be provisioned with requested AOE.

Table 8-2: Job Substates

Substate Number	Substate Description
72	Waiting to join job
91	Job is terminated
92	Job is finished
93	Job failed
94	Job was moved
153	(Set by MoM) Mother Superior waiting for delete ACK from sisters

8.2 Job Array States

Job array states map closely to job states except for the '*B*' state. The '*B*' state applies to job arrays and indicates that at least one subjob has left the queued state and is running or has run, but not all subjobs have run. Job arrays will never be in the '*R*', '*S*' or '*U*' states.

Table 8-3: Job Array States

State	Numeric	Indication
B	*7*	The job array has started
E	*5*	All subjobs are finished and the server is cleaning up the job array
F	*9*	The job array is finished
H	*2*	The job array is held
Q	*1*	The job array is queued, or has been qrerun
T	*0*	The job array is in transit between servers
W	*3*	The job array is waiting for its execution time to be reached, or job array was delayed due to stagein failure

8.3 Subjob States

Subjobs can be in one of six states, listed here.

Table 8-4: Subjob States

State	Numeric	Indication
E	*5*	Ending
F	*9*	Finished
Q	*1*	Queued
R	*4*	Running

Table 8-4: Subjob States

State	Numeric	Indication
S	*None; sub-state of Running*	Suspended
U	*None; sub-state of Running*	Suspended by keyboard activity
X	*6*	Expired or deleted; subjob has completed execution or been deleted

8.4 Server States

The state of the server is shown in the server_state server attribute. Possible values are shown in the following table:

Table 8-5: Server States

State	Description
Hot_Start	The server has been started so that it will run first any jobs that were running when the server was shut down. Python type: pbs.SV_STATE_HOT
Idle	The server is running. The scheduler is between scheduling cycles. Python type: pbs.SV_STATE_IDLE
Scheduling	The server is running. The scheduler is in a scheduling cycle. Python type: pbs.SV_STATE_ACTIVE
Terminating	The server is terminating. Python type: pbs.SV_STATE_SHUTIMM or pbs.SV_STATE_SHUTSIG
Terminating_Delayed	The server is terminating in delayed mode. No new jobs will be run, and the server will shut down when the last running job finishes. Python type: pbs.SV_STATE_SHUTDEL

8.5 Vnode States

If a vnode's state attribute is unset, that is equivalent to the state being *free*. A vnode's state is shown in its state attribute, which can take on zero or more of the values listed here. Some vnode state values can be set simultaneously. Values are:

Table 8-6: Vnode States

State Name	Set By	Description	Can Combine With these States
busy	Server	Node is up and has load average greater than max_load, or is showing keyboard or mouse activity. When the loadave is above max_load, that node is marked *busy*. A scheduler won't place jobs on a node marked *busy*. When the loadave drops below ideal_load, or when the mouse and keyboard have not shown any activity for a specified amount of time, the *busy* mark is removed. Consult your OS documentation to determine values that make sense.	*offline* *maintenance*
down	Server	Node is not usable. Existing communication lost between server and MoM.	*maintenance* Cannot be set with *free*
free	Server	Node is up and has available CPU(s). Server will mark a vnode "*free*" on first successful ping after vnode was "*down*".	None
job-busy	Server	Node is up and all CPUs are allocated to jobs.	*offline* *resv-exclusive*
job-exclusive	Server	Node is up and has been allocated exclusively to a single job.	*offline* *resv-exclusive*
maintenance	Server	A vnode enters the *maintenance* state when any of its jobs is suspended with the *admin-suspend* signal. Other jobs running on this vnode continue to run; each job must be *admin-suspend*ed. The vnode leaves the *maintenance* state when the last job is resumed with the *admin-resume* signal. A scheduler does not start or resume jobs on a node in the *maintenance* state. Any reservations on vnodes in the *maintenance* state are marked *degraded*. PBS searches for alternate vnodes for those reservations.	*down* *offline*
offline	Manager Operator	Node is not usable. Jobs running on this vnode will continue to run. Used by Manager/Operator to mark a vnode not to be used for jobs.	*busy* *job-busy* *job-exclusive* *resv-exclusive*
powered-off		Indicates that this vnode was powered off by PBS via power provisioning. This tells the scheduler that it can schedule jobs on this vnode; in that case PBS powers the vnode back up.	
powering-down		Indicates that this vnode is in the process of being powered down by PBS via power provisioning.	

Table 8-6: Vnode States

State Name	Set By	Description	Can Combine With these States
powering-on		Indicates that this vnode is in the process of being powered up by PBS via power provisioning.	
provisioning	Server	A vnode is in the provisioning state while it is in the process of being provisioned. No jobs are run on vnodes in the provisioning state.	Cannot be set with any other states
resv-exclusive	Server	Reservation has requested exclusive use of vnode, and reservation is running.	*job-exclusive, offline*
sleep	Server	Indicates that this vnode was ramped down or powered off via PBS power management. This tells the scheduler that it can schedule jobs on this vnode; in that case PBS powers the vnode back up.	
stale	Server	MoM managing vnode is not reporting any information about this vnode, but was reporting it previously. Server can still communicate with MoM. A vnode becomes *stale* when: 1. A vnode is defined in the server 2. MoM starts or restarts and reports a set of vnodes according to her configuration 3. A vnode which existed in the server earlier is not in the set being reported now by MoM 4. That vnode is marked "*stale*"	Cannot be set with *free*
state-unknown, down	Server	Node is not usable. Since server's latest start, no communication with this vnode. May be network or hardware problem, or no MoM on vnode.	
unresolvable	Server	Server cannot resolve name of vnode	
wait-provisioning	Server	There is a limit on the maximum number of vnodes that can be in the provisioning state. This limit is specified in the server's max_concurrent_provision attribute. If a vnode is to be provisioned, but cannot because the number of concurrently provisioning vnodes has reached the specified maximum, the vnode goes into the *wait-provisioning state*. No jobs are run on vnodes in the *wait-provisioning* state.	Cannot be set with any other states

8.6 Reservation States

The following table shows the list of possible states for a reservation. The states that you will usually see are *CO*, *UN*, *BD*, and *RN*, although a reservation usually remains unconfirmed for too short a time to see that state.

Table 8-7: Reservation States

Numeric	Code	State	Description
0	*NO*	*RESV_NONE*	No reservation yet
1	*UN*	*RESV_UNCONFIRMED*	Reservation not confirmed
2	*CO*	*RESV_CONFIRMED*	Reservation confirmed
3	*WT*	*RESV_WAIT*	Unused
4	*TR*	*RESV_TIME_TO_RUN*	Transitory state; reservation's start time has arrived
5	*RN*	*RESV_RUNNING*	Time period from reservation's start time to end time is being traversed
6	*FN*	*RESV_FINISHED*	Transitory state; reservation's end time has arrived and reservation will be deleted
7	*BD*	*RESV_BEING_DELETED*	Transitory state; reservation is being deleted
8	*DE*	*RESV_DELETED*	Transitory state; reservation has been deleted
9	*DJ*	*RESV_DELETING_JOBS*	Jobs remaining after reservation's end time being deleted
10	*DG*	*RESV_DEGRADED*	Vnode(s) allocated to reservation unavailable
11	*AL*	*RESV_BEING_ALTERED*	Transitory state; reservation is being altered
12	*IC*	*RESV_IN_CONFLICT*	This reservation conflicts with a maintenance reservation

8.6.1 Degraded Reservation Substates

The following table shows states and substates for degraded reservations:

Table 8-8: Degraded Reservation States and Substates

Occurrence Type	Reservation Time Is Now		Reservation Time in Future	
	State	Substate	State	Substate
Advance and job-specific reservation: running	*RESV_RUNNING*	*RESV_DEGRADED*	*RESV_DEGRADED*	*RESV_DEGRADED*
Advance and job-specific reservation: conflicts with maintenance reservation	*RESV_DEGRADED*	*RESV_IN_CONFLICT*	*RESV_DEGRADED*	*RESV_IN_CONFLICT*
Standing reservation soonest occurrence: running	*RESV_RUNNING*	*RESV_DEGRADED*	*RESV_DEGRADED*	*RESV_DEGRADED*
Standing reservation soonest occurrence: conflicts with maintenance reservation	*RESV_DEGRADED*	*RESV_IN_CONFLICT*	*RESV_DEGRADED*	*RESV_IN_CONFLICT*
Standing reservation non-soonest occurrence only: conflicts with maintenance reservation	*N/A*	*N/A*	*RESV_CONFIRMED*	*RESV_DEGRADED*
	N/A	*N/A*	*RESV_RUNNING*	*RESV_RUNNING*

9 The PBS Configuration File

9.1 Format of Configuration File

Each line in the /etc/pbs.conf file gives a value for one parameter, or is a comment, or is blank. The order of the elements is not important.

9.1.1 Specifying Parameters

When you specify a parameter value, do not include any spaces in the line. Format for specifying a parameter value:

<parameter>=<value>

For example, to specify a value for PBS_START_MOM on the local host:

```
PBS_START_MOM=1
```

9.1.2 Comment Lines in Configuration File

You can comment out lines you are not using. Precede a comment with the hashmark ("#"). For example:

```
#This is a comment line
```

9.2 Contents of Configuration File

The /etc/pbs.conf file contains configuration parameters for PBS. The following table describes the parameters you can use in the pbs.conf configuration file:

Table 9-1: Parameters in pbs.conf

Parameter	Description
PBS_AUTH_METHOD	Specifies default authentication method and library to be used by PBS. Used only at authenticating client. Case-insensitive. Default value: *resvport* To use MUNGE, set to *munge*
PBS_BATCH_SERVICE_PORT	Port on which server listens. Default: 15001
PBS_BATCH_SERVICE_PORT_DIS	DIS port on which server listens.
PBS_COMM_LOG_EVENTS	Communication daemon log mask. Default: *511*
PBS_COMM_ROUTERS	Tells a pbs_comm the location of the other pbs_comms.
PBS_COMM_THREADS	Number of threads for communication daemon.

Table 9-1: Parameters in pbs.conf

Parameter	Description
PBS_CORE_LIMIT	Limit on corefile size for PBS daemons. Can be set to an integer number of bytes or to the string "unlimited". If unset, core file size limit is inherited from the shell environment.
PBS_CP	Specifies command for MoM to use for local copy
PBS_DAEMON_SERVICE_USER	Username under which scheduler(s) run. Default: root
PBS_DATA_SERVICE_PORT	Used to specify non-default port for connecting to data service. Default: 15007
PBS_ENCRYPT_METHOD	Specifies method and library for encrypting and decrypting data in client-server communication. Used only at authentication client side. Case-insensitive. To use TLS encryption in client-server communication, set this parameter to *tls*. No default; if this is not set, PBS does not encrypt or decrypt data.
PBS_ENVIRONMENT	Location of `pbs_environment` file.
PBS_EXEC	Location of PBS `bin` and `sbin` directories.
PBS_HOME	Location of PBS working directories.
PBS_LEAF_NAME	Tells endpoint what hostname to use for network. The value does not include a port, since that is usually set by the daemon. By default, the name of the endpoint's host is the hostname of the machine. You can set the name where an endpoint runs. This is useful when you have multiple networks configured, and you want PBS to use a particular network. The server only queries for the canonicalized address of the MoM host, unless you let it know via the Mom attribute; if you have set PBS_LEAF_NAME in `/etc/pbs.conf` to something else, make sure you set the Mom attribute at vnode creation. TPP internally resolves the name to a set of IP addresses, so you do not affect how `pbs_comm` works.
PBS_LEAF_ROUTERS	Location of endpoint's `pbs_comm` daemon(s).
PBS_LOCALLOG=<value>	Enables logging to local PBS log files. Valid values: 0: no local logging 1: local logging enabled Only available when using `syslog`.
PBS_LOG_HIGHRES_TIMESTAMP	Controls whether daemons on this host log timestamps in microseconds. Default timestamp log format is *HH:MM:SS*. With microsecond logging, format is *HH:MM:SS:XXXXXX*. Does not affect accounting log. Not applicable when using `syslog`. Overridden by environment variable of the same name. Valid values: *0*, *1*. Default: *0* (no microsecond logging)

Table 9-1: Parameters in pbs.conf

Parameter	Description
PBS_MAIL_HOST_NAME	Used in addressing mail regarding jobs and reservations that is sent to users specified in a job or reservation's Mail_Users attribute. Optional. If specified, must be a fully qualified domain name. Cannot contain a colon (":"). For how this is used in email address, see section 2.2.3, "Specifying Mail Delivery Domain", on page 22.
PBS_MANAGER_SERVICE_PORT	Port on which MoM listens. Default: 15003
PBS_MOM_HOME	Location of MoM working directories.
PBS_MOM_NODE_NAME	Name that MoM should use for parent vnode, and if they exist, child vnodes. If this is not set, MoM defaults to using the non-canonicalized hostname returned by `gethostname()`. If you use the IP address for a vnode name, set `PBS_MOM_NODE_NAME=<IP address>` in `pbs.conf` on the execution host. Dots are not allowed in this parameter unless they are part of an IP address.
PBS_MOM_SERVICE_PORT	Port on which MoM listens. Default: 15002
PBS_OUTPUT_HOST_NAME	Host to which all job standard output and standard error are delivered. If specified in `pbs.conf` on a job submission host, the value of PBS_OUTPUT_HOST_NAME is used in the host portion of the job's Output_Path and Error_Path attributes. If the job submitter does not specify paths for standard output and standard error, the current working directory for the `qsub` command is used, and the value of PBS_OUTPUT_HOST_NAME is appended after an at sign ("@"). If the job submitter specifies only a file path for standard output and standard error, the value of PBS_OUTPUT_HOST_NAME is appended after an at sign ("@"). If the job submitter specifies paths for standard output and standard error that include host names, the specified paths are used. Optional. If specified, must be a fully qualified domain name. Cannot contain a colon (":"). See "Delivering Output and Error Files" on page 60 in the PBS Professional Administrator's Guide.
PBS_PRIMARY	Hostname of primary server. Used only for failover configuration. Overrides PBS_SERVER_HOST_NAME. If you set PBS_LEAF_NAME on the primary server host, make sure that PBS_PRIMARY matches PBS_LEAF_NAME on the corresponding host. If you do not set PBS_LEAF_NAME on the server host, make sure that PBS_PRIMARY matches the hostname of the server host.
PBS_RCP	Location of `rcp` command if `rcp` is used.
PBS_REMOTE_VIEWER	Specifies remote viewer client. If not specified, PBS uses native Remote Desktop client for remote viewer. Set on submission host(s). Supported on Windows only.

Table 9-1: Parameters in pbs.conf

Parameter	Description
PBS_SCHED_THREADS	Maximum number of scheduler threads. Scheduler automatically caps number of threads at the number of cores (or hyperthreads if applicable), regardless of value of this variable. Overridden by `pbs_sched -t` option and PBS_SCHED_THREADS environment variable. Default: 1
PBS_SCP	Location of `scp` command if `scp` is used; setting this parameter causes PBS to first try `scp` rather than `rcp` for file transport.
PBS_SECONDARY	Hostname of secondary server. Used only for failover configuration. Overrides PBS_SERVER_HOST_NAME. If you set PBS_LEAF_NAME on the secondary server host, make sure that PBS_SECONDARY matches PBS_LEAF_NAME on the corresponding host. If you do not set PBS_LEAF_NAME on the server host, make sure that PBS_SECONDARY matches the hostname of the server host.
PBS_SERVER	Hostname of host running the server. Cannot be longer than 255 characters. If the short name of the server host resolves to the correct IP address, you can use the short name for the value of the PBS_SERVER entry in `pbs.conf`. If only the FQDN of the server host resolves to the correct IP address, you must use the FQDN for the value of PBS_SERVER. Overridden by PBS_SERVER_HOST_NAME and PBS_PRIMARY.
PBS_SERVER_HOST_NAME	The FQDN of the server host. Used by clients to contact server. Overridden by PBS_PRIMARY and PBS_SECONDARY failover parameters. Overrides PBS_SERVER parameter. Optional. If specified, must be a fully qualified domain name. Cannot contain a colon (":"). See "Contacting the Server" on page 60 in the PBS Professional Administrator's Guide.
PBS_START_COMM	Set this to *1* if a communication daemon is to run on this host.
PBS_START_MOM	Default is *0*. Set this to *1* if a MoM is to run on this host.
PBS_START_SCHED	**Deprecated**. Set this to *1* if default scheduler is to run on this host. Overridden by scheduler's scheduling attribute.
PBS_START_SERVER	Set this to *1* if server is to run on this host.
PBS_SUPPORTED_AUTH_METHODS	Specifies supported authentication methods for client-server communication. Used by authenticating server (PBS server, scheduler, MoM, or comm); ignored at client. Case-insensitive. If this parameter is set, PBS accepts only the methods listed. Format: comma-separated list of authentication methods. Default value: *resvport* Example: *munge,GSS*

Table 9-1: Parameters in pbs.conf

Parameter	Description
PBS_SYSLOG=<value>	Controls use of `syslog` facility under which the entries are logged. Valid values: 0: no syslogging 1: logged via LOG_DAEMON facility 2: logged via LOG_LOCAL0 facility 3: logged via LOG_LOCAL1 facility ... 9: logged via LOG_LOCAL7 facility
PBS_SYSLOGSEVR=<value>	Filters `syslog` messages by severity. Valid values: 0: only LOG_EMERG messages are logged 1: messages up to LOG_ALERT are logged ... 7: messages up to LOG_DEBUG are logged
PBS_TMPDIR	Location of temporary files/directories used by PBS components.

10 Log Levels

10.1 Log Levels

PBS allows specification of the types of events that are logged for each daemon. Each type of log event has a different log level. All daemons use the same log level for the same type of event.

The following table lists the log level for each type of event.

Table 10-1: PBS Events and Log Levels

Name	Decimal	Hex	Event Description
PBSEVENT_ERROR	1	0x0001	Internal PBS errors
PBSEVENT_SYSTEM	2	0x0002	System (OS) errors, such as malloc failure
PBSEVENT_ADMIN	4	0x0004	Administrator-controlled events, such as changing queue attributes
PBSEVENT_JOB	8	0x0008	Job related events, e.g. submitted, ran, deleted
PBSEVENT_JOB_USAGE	16	0x0010	Job resource usage
PBSEVENT_SECURITY	32	0x0020	Security related events
PBSEVENT_SCHED	64	0x0040	When the scheduler was called and why
PBSEVENT_DEBUG	128	0x0080	Common debug messages
PBSEVENT_DEBUG2	256	0x0100	Debug event class 2
PBSEVENT_RESV	512	0x0200	Reservation-related messages
PBSEVENT_DEBUG3	1024	0x0400	Debug event class 3. Debug messages rarer than event class 2.
PBSEVENT_DEBUG4	2048	0x0800	Debug event class 4. Limit-related messages.

11
Job Exit Status

11.1 Job Exit Status

The exit status of a job may fall in one of three ranges, listed in the following table:

Table 11-1: Job Exit Status Ranges

Exit Status Range	Reason	Description
X < 0	The job could not be executed	See Table 11-2, "Job Exit Codes," on page 377
0 <=X < 128	Exit value of shell or top process	This is the exit value of the top process in the job, typically the shell. This may be the exit value of the last command executed in the shell or the `.logout` script if the user has such a script (`csh`). The exit status of an interactive job is always recorded as 0 (zero), regardless of the actual exit status.
X >=128	Job was killed with a signal	This means the job was killed with a signal. The signal is given by X modulo 128 (or 256). For example an exit value of 137 means the job's top process was killed with signal 9 (137 % 128 = 9). The exit status values greater than 128 (or 256) indicate which signal killed the job. Depending on the system, values greater than 128 (or on some systems 256; see `wait(2)` or `waitpid(2)` for more information), are the value of the signal that killed the job. To interpret (or "decode") the signal contained in the exit status value, subtract the base value from the exit status. For example, if a job had an exit status of 143, that indicates the job was killed via a SIGTERM (e.g. 143 - 128 = 15, signal 15 is SIGTERM). See the `kill(1)` manual page for a mapping of signal numbers to signal name on your operating system.

The exit status of jobs is recorded in the PBS server logs and the accounting logs.

Negative exit status indicates that the job could not be executed. Negative exit values are listed in the table below:

Table 11-2: Job Exit Codes

Exit Code	Name	Description
0	*JOB_EXEC_OK*	Job execution was successful
-1	*JOB_EXEC_FAIL1*	Job execution failed, before files, no retry
-2	*JOB_EXEC_FAIL2*	Job execution failed, after files, no retry

Table 11-2: Job Exit Codes

Exit Code	Name	Description
-3	*JOB_EXEC_RETRY*	Job execution failed, do retry
-4	*JOB_EXEC_INITABT*	Job aborted on MoM initialization
-5	*JOB_EXEC_INITRST*	Job aborted on MoM initialization, checkpoint, no migrate
-6	*JOB_EXEC_INITRMG*	Job aborted on MoM initialization, checkpoint, ok migrate
-7	*JOB_EXEC_BADRESRT*	Job restart failed
-10	*JOB_EXEC_FAILUID*	Invalid UID/GID for job
-11	*JOB_EXEC_RERUN*	Job was rerun
-12	*JOB_EXEC_CHKP*	Job was checkpointed and killed
-13	*JOB_EXEC_FAIL_PASSWORD*	Job failed due to a bad password
-14	*JOB_EXEC_RERUN_ ON_SIS_FAIL*	Job was requeued (if rerunnable) or deleted (if not) due to a communication failure between the primary execution host MoM and a Sister
-15	JOB_EXEC_QUERST	Requeue job for restart from checkpoint
-16	JOB_EXEC_FAILHOOK_RERUN	Job execution failed due to hook rejection; requeue for later retry
-17	JOB_EXEC_FAILHOOK_DELETE	Job execution failed due to hook rejection; delete the job at end
-18	JOB_EXEC_HOOK_RERUN	A hook requested for job to be requeued
-19	JOB_EXEC_HOOK_DELETE	A hook requested for job to be deleted
-20	JOB_EXEC_RERUN_MS_FAIL	Job requeued because server couldn't contact the primary execution host MoM

12 Example Configurations

This chapter shows some configuration-specific scenarios which will hopefully clarify any configuration questions. Several configuration models are discussed, followed by several examples of specific features.

- Single Vnode System
- Single Vnode System with Separate PBS server
- Multi-vnode complex
- Multi-level Route Queues (including group ACLs)
- Multiple User ACLs

For each of these possible configuration models, the following information is provided:

- General description for the configuration model
- Type of system for which the model is well suited
- Contents of server nodes file
- Any required server configuration
- Any required MoM configuration
- Any required scheduler configuration

12.1 Single Vnode System

Running PBS on a single vnode/host as a standalone system is the least configuration. This model is most applicable to sites who have a single large server system. In this model, all PBS components run on the same host, which is the same host on which jobs will be executed. The following illustration shows how communication works when PBS is on a single host in TPP mode. For more on TPP mode, see Chapter 4, "Communication", on page 45.

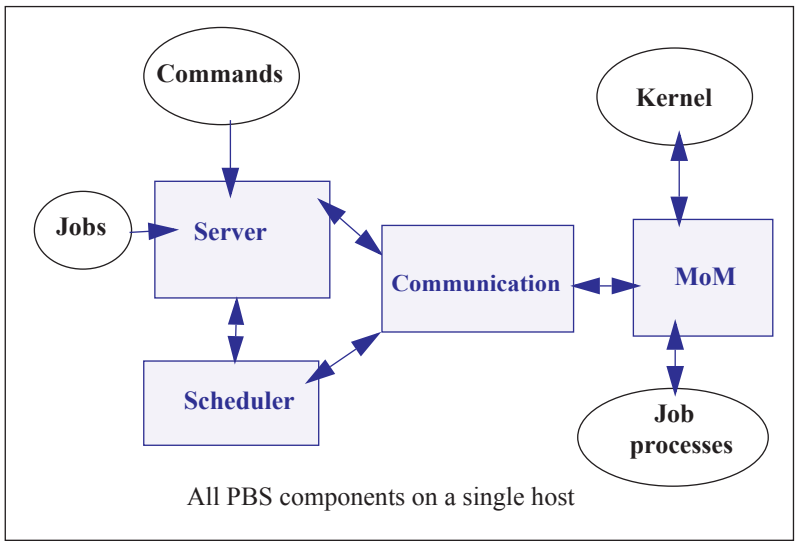

Figure 12-1:PBS daemons on a single execution host

For this example, let's assume we have a 32-CPU server machine named "mars". We want users to log into mars and jobs will be run via PBS on mars.

In this configuration, the server's default `nodes` file (which should contain the name of the host on which the server was installed) is sufficient. Our example `nodes` file would contain only one entry: `mars`

The default MoM and scheduler `config` files, as well as the default queue/Server limits are also sufficient in order to run jobs. No changes are required from the default configuration, however, you may wish to customize PBS to your site.

12.2 Separate Server and Execution Host

A variation on the model presented above would be to provide a "front-end" system that ran the PBS server, scheduler, and communication daemons, and from which users submitted their jobs. Only the MoM would run on our execution server, mars. This model is recommended when the user load would otherwise interfere with the computational load on the server. The following illustration shows how communication works when the PBS server and scheduler are on a front-end system and MoM is on a separate host, in TPP mode. For more on TPP mode, see Chapter 4, "Communication", on page 45.

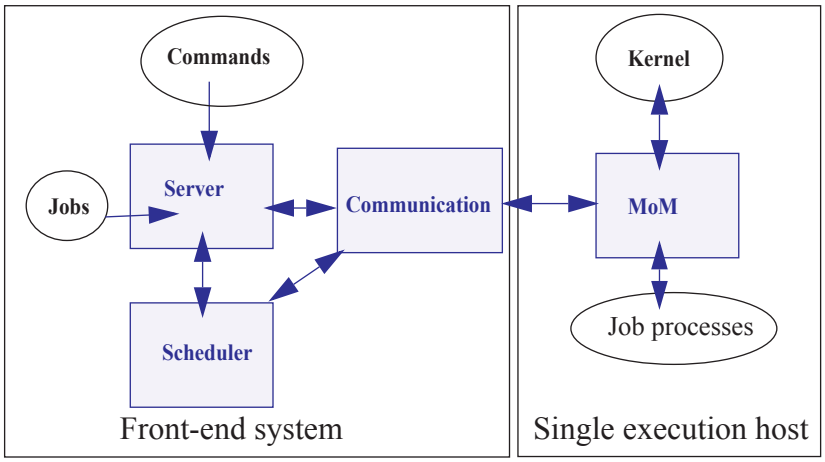

Figure 12-2:PBS daemons on single execution system with front end

In this case, the PBS `server_priv/nodes` file would contain the name of our execution server mars, but this may not be what was written to the file during installation, depending on which options were selected. It is possible the hostname of the machine on which the server was installed was added to the file, in which case you would need to use `qmgr(1B)` to manipulate the contents to contain one vnode: `mars`. If the default scheduling policy, based on available CPUs and memory, meets your requirements, no changes are required in either the MoM or scheduler configuration files.

However, if you wish the execution host (mars) to be scheduled based on load average, the following changes are needed. Edit MoM's `mom_priv/config` file so that it contains the target and maximum load averages:

```
$ideal_load 30
$max_load 32
```

12.3 Multiple Execution Hosts

The multi-vnode complex model is a very common configuration for PBS. In this model, there is typically a front-end system as we saw in the previous example, with a number of back-end execution hosts. The PBS server, scheduler, and communication daemons are typically run on the front-end system, and a MoM is run on each of the execution hosts, as shown in the diagram to the right.

In this model, the server's `nodes` file will need to contain the list of all the vnodes in the complex.

The following diagram illustrates an eight-host complex in TPP mode.

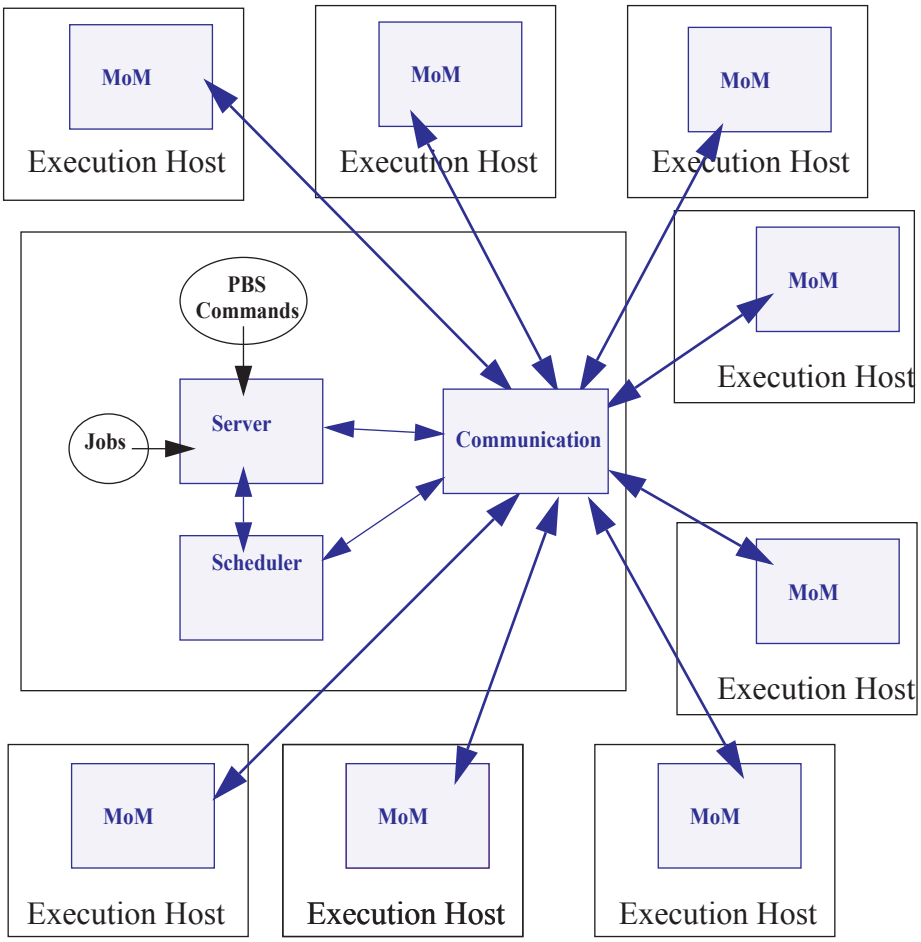

Figure 12-3:Typical PBS daemon locations for multiple execution hosts

This diagram illustrates a multi-vnode complex TPP configuration wherein the server and scheduler daemons communicate with the MoMs on the execution hosts via the communication daemon. Jobs are submitted to the server, scheduled for execution by the partition scheduler, and then transferred to a MoM when it's time to be run. MoM periodically sends status information back to the server, and answers resource requests from the scheduler.

12.4 Multi-level Route Queues

There are times when a site may wish to create a series of route queues in order to filter jobs, based on specific resources, or possibly to different destinations. For this example, consider a site that has two large server systems, and a Linux cluster. The Administrator wants to configure route queues such that everyone submits jobs to a single queue, but the jobs get routed based on (1) requested architecture and (2) individual group IDs. In other words, users request the architecture they want, and PBS finds the right queue for them. Only groups "math", "chemistry", and "physics" are permitted to use either server systems; while anyone can use the cluster. Lastly, the jobs coming into the cluster should be divided into three separate queues for long, short, and normal jobs. But the "long" queue was created for the astronomy department, so only members of that group should be permitted into that queue. Given these requirements, let's look at how we would set up such a collection of route queues. (Note that this is only one way to accomplish this task. There are various other ways too.)

First we create a queue to which everyone will submit their jobs. Let's call it "submit". It will need to be a route queue with three destinations, as shown:

```
Qmgr: create queue submit
Qmgr: set queue submit queue_type = Route
Qmgr: set queue submit route_destinations = server_1
Qmgr: set queue submit route_destinations += server_2
Qmgr: set queue submit route_destinations += cluster
Qmgr: set queue submit enabled = True
Qmgr: set queue submit started = True
```

Now we need to create the destination queues. (Notice in the above example, we have already decided what to call the three destinations: `server_1`, `server_2`, `cluster`.) First we create the `server_1` queue, complete with a group ACL, and a specific architecture limit.

```
Qmgr: create queue server_1
Qmgr: set queue server_1 queue_type = Execution
Qmgr: set queue server_1 from_route_only = True
Qmgr: set queue server_1 resources_max.arch = linux
Qmgr: set queue server_1 resources_min.arch = linux
Qmgr: set queue server_1 acl_group_enable = True
Qmgr: set queue server_1 acl_groups = math
Qmgr: set queue server_1 acl_groups += chemistry
Qmgr: set queue server_1 acl_groups += physics
Qmgr: set queue server_1 enabled = True
Qmgr: set queue server_1 started = True
```

Next we create the queues for `server_2` and `cluster`. Note that the `server_2` queue is very similar to the `server_1` queue, only the architecture differs. Also notice that the `cluster` queue is another route queue, with multiple destinations.

```
Qmgr: create queue server_2
Qmgr: set queue server_2 queue_type = Execution
Qmgr: set queue server_2 from_route_only = True
Qmgr: set queue server_2 resources_max.arch = sv2
Qmgr: set queue server_2 resources_min.arch = sv2
Qmgr: set queue server_2 acl_group_enable = True
Qmgr: set queue server_2 acl_groups = math
Qmgr: set queue server_2 acl_groups += chemistry
Qmgr: set queue server_2 acl_groups += physics
Qmgr: set queue server_2 enabled = True
Qmgr: set queue server_2 started = True
Qmgr: create queue cluster
Qmgr: set queue cluster queue_type = Route
Qmgr: set queue cluster from_route_only = True
Qmgr: set queue cluster resources_max.arch = linux
Qmgr: set queue cluster resources_min.arch = linux
Qmgr: set queue cluster route_destinations = long
Qmgr: set queue cluster route_destinations += short
Qmgr: set queue cluster route_destinations += medium
Qmgr: set queue cluster enabled = True
Qmgr: set queue cluster started = True
```

In the cluster queue above, you will notice the particular order of the three destination queues (`long`, `short`, `medium`). PBS will attempt to route a job into the destination queues in the order specified. Thus, we want PBS to first try the `long` queue (which will have an ACL on it), then the `short` queue (with its short time limits). Thus any jobs that had not been routed into any other queues (server or cluster) will end up in the `medium` cluster queue. Now to create the remaining queues.

```
Qmgr: create queue long
Qmgr: set queue long queue_type = Execution
Qmgr: set queue long from_route_only = True
Qmgr: set queue long resources_max.cput = 20:00:00
Qmgr: set queue long resources_max.walltime = 20:00:00
Qmgr: set queue long resources_min.cput = 02:00:00
Qmgr: set queue long resources_min.walltime = 03:00:00
Qmgr: set queue long acl_group_enable = True
Qmgr: set queue long acl_groups = astronomy
Qmgr: set queue long enabled = True
Qmgr: set queue long started = True

Qmgr: create queue short
Qmgr: set queue short queue_type = Execution
Qmgr: set queue short from_route_only = True
Qmgr: set queue short resources_max.cput = 01:00:00
Qmgr: set queue short resources_max.walltime = 01:00:00
Qmgr: set queue short enabled = True
Qmgr: set queue short started = True
Qmgr: create queue medium
Qmgr: set queue medium queue_type = Execution
Qmgr: set queue medium from_route_only = True
Qmgr: set queue medium enabled = True
Qmgr: set queue medium started = True
Qmgr: set server default_queue = submit
```

Notice that the `long` and `short` queues have time limits specified. This will ensure that jobs of certain sizes will enter (or be prevented from entering) these queues. The last queue, `medium`, has no limits, thus it will be able to accept any job that is not routed into any other queue.

Lastly, note the last line in the example above, which specified that the default queue is the new `submit` queue. This way users will simply submit their jobs with the resource and architecture requests, without specifying a queue, and PBS will route the job into the correct location. For example, if a user submitted a job with the following syntax, the job would be routed into the `server_2` queue:

```
qsub -l select=arch=sv2:ncpus=4 testjob
```

12.5 External Software License Management

PBS Professional can be configured to schedule jobs based on externally-controlled licensed software. A detailed example is provided in "Example of Floating, Externally-managed License with Features" on page 272 in the PBS Professional Administrator's Guide.

12.6 Multiple User ACL Example

A site may have a need to restrict individual users to particular queues. In the previous example we set up queues with group-based ACLs, in this example we show user-based ACLs. Say a site has two different groups of users, and wants to limit them to two separate queues (perhaps with different resource limits). The following example illustrates this.

```
Qmgr: create queue structure
Qmgr: set queue structure queue_type = Execution
Qmgr: set queue structure acl_user_enable = True
Qmgr: set queue structure acl_users = curly
Qmgr: set queue structure acl_users += jerry
Qmgr: set queue structure acl_users += larry
Qmgr: set queue structure acl_users += moe
Qmgr: set queue structure acl_users += tom
Qmgr: set queue structure resources_max.nodes = 48
Qmgr: set queue structure enabled = True
Qmgr: set queue structure started = True

Qmgr: create queue engine
Qmgr: set queue engine queue_type = Execution
Qmgr: set queue engine acl_user_enable = True
Qmgr: set queue engine acl_users = bill
Qmgr: set queue engine acl_users += bobby
Qmgr: set queue engine acl_users += chris
Qmgr: set queue engine acl_users += jim
Qmgr: set queue engine acl_users += mike
Qmgr: set queue engine acl_users += rob
Qmgr: set queue engine acl_users += scott
Qmgr: set queue engine resources_max.nodes = 12
Qmgr: set queue engine resources_max.walltime=04:00:00
Qmgr: set queue engine enabled = True
Qmgr: set queue engine started = True
```

13
Run Limit Error Messages

This chapter lists the error messages generated when limits are exceeded. See "Managing Resource Usage By Users, Groups, and Projects, at Server & Queues" on page 283 in the PBS Professional Administrator's Guide.

13.1 Run Limit Error Messages

When a job would exceed a limit by running, the job's comment field is set to one of the following messages. The following table shows the limit attribute, where the limit is applied, to whom the limit is applied, and the message.

Table 13-1: Job Run Limit Error Messages

Attribute	Where Applied	To What Applied	Message
max_run	queue	o: PBS_ALL	Not Running: Queue <queue name> job limit has been reached.
max_run	server	o: PBS_ALL	Not Running: Server job limit has been reached.
max_run	server	p:PBS_GENERIC	Not Running: Project has reached server running limit.
max_run	queue	p:PBS_GENERIC	Not Running: Project has reached queue<queue-name>'s running limit.
max_run	server	p:<project name>	Not Running: Server job limit reached for project <project name>
max_run	queue	p:<project name>	Not Running: Queue <queue-name> job limit reached for project <project name>
max_run	queue	g: PBS_GENERIC	Not Running: Group has reached queue <queue name> running limit.
max_run	server	g: PBS_GENERIC	Not Running: Group has reached server running limit.
max_run	queue	u: PBS_GENERIC	Not Running: User has reached queue <queue name> running job limit.
max_run	server	u: PBS_GENERIC	Not Running: User has reached server running job limit.
max_run	queue	g:<group name>	Queue <queue name> job limit reached for group <G>
max_run	server	g:<group name>	Server job limit reached for group <G>
max_run	queue	u:<user name>	Queue <queue name> job limit reached for user <U>
max_run	server	u:<user name>	Server job limit reached for user <U>
max_run_res	queue	o: PBS_ALL	Queue <queue name> job limit reached on resource <resource name>
max_run_res	server	o: PBS_ALL	Server job limit reached on resource <resource name>

Table 13-1: Job Run Limit Error Messages

Attribute	Where Applied	To What Applied	Message
max_run_res	queue	p:PBS_GENERIC	Not Running: Queue <queue name> per-project limit reached on resource <resource name>
max_run_res	server	p:PBS_GENERIC	Not Running: Server per-project limit reached on resource <resource name>
max_run_res	server	p:<project name>	Not Running: would exceed project <project_name>'s limit on resource <resource name> in complex
max_run_res	queue	p:<project name>	Not Running: would exceed project <project_name>'s limit on resource <resource name> in queue <queue-name>
max_run_res	queue	g: PBS_GENERIC	Queue <queue name> per-group limit reached on resource <resource name>
max_run_res	server	g: PBS_GENERIC	Server per-group limit reached on resource <resource name>
max_run_res	queue	u: PBS_GENERIC	Queue <queue name> per-user limit reached on resource <resource name>
max_run_res	server	u: PBS_GENERIC	Server per-user limit reached on resource <resource name>
max_run_res	queue	g:<group name>	would exceed group <G>'s limit on resource <resource name> in queue <queue name>
max_run_res	server	g:<group name>	would exceed group <G>'s limit on resource <resource name> in complex
max_run_res	queue	u:<user name>	would exceed user <U>'s limit on resource <resource name> in queue <queue name>
max_run_res	server	u:<user name>	would exceed user <U>'s limit on resource <resource name> in complex

14
Error Codes

The following table lists all the PBS error codes, their textual names, and a description of each.

Table 14-1: Error Codes

Error Name	Error Code	Description
PBSE_NONE	0	No error
PBSE_UNKJOBID	15001	Unknown Job Identifier
PBSE_NOATTR	15002	Undefined Attribute
PBSE_ATTRRO	15003	Attempt to set READ ONLY attribute
PBSE_IVALREQ	15004	Invalid request
PBSE_UNKREQ	15005	Unknown batch request
PBSE_TOOMANY	15006	Too many submit retries
PBSE_PERM	15007	No permission
PBSE_BADHOST	15008	Access from host not allowed
PBSE_JOBEXIST	15009	Job already exists
PBSE_SYSTEM	15010	System error occurred
PBSE_INTERNAL	15011	Internal server error occurred
PBSE_REGROUTE	15012	Parent job of dependent in route queue
PBSE_UNKSIG	15013	Unknown signal name
PBSE_BADATVAL	15014	Bad attribute value
PBSE_MODATRRUN	15015	Cannot modify attribute in run state
PBSE_BADSTATE	15016	Request invalid for job state
PBSE_UNKQUE	15018	Unknown queue name
PBSE_BADCRED	15019	Invalid Credential in request
PBSE_EXPIRED	15020	Expired Credential in request
PBSE_QUNOENB	15021	Queue not enabled
PBSE_QACESS	15022	No access permission for queue

Table 14-1: Error Codes

Error Name	Error Code	Description
PBSE_BADUSER	15023	Missing userID, username, or GID. Returned under following conditions: 1. User does not have a password entry (getpwnam() returns null). 2. User's UID is zero and root isn't allowed to run jobs (acl_roots). 3. PBS_O_HOST is not set in the job.
PBSE_HOPCOUNT	15024	Max hop count exceeded
PBSE_QUEEXIST	15025	Queue already exists
PBSE_ATTRTYPE	15026	Incompatible queue attribute type
PBSE_OBJBUSY	15027	Object Busy
PBSE_QUENBIG	15028	Queue name too long
PBSE_NOSUP	15029	Feature/function not supported
PBSE_QUENOEN	15030	Can't enable queue, lacking definition
PBSE_PROTOCOL	15031	Protocol (ASN.1) error. Message is distorted or truncated.
PBSE_BADATLST	15032	Bad attribute list structure
PBSE_NOCONNECTS	15033	No free connections
PBSE_NOSERVER	15034	No server to connect to
PBSE_UNKRESC	15035	Unknown resource
PBSE_EXCQRESC	15036	Job exceeds Queue resource limits
PBSE_QUENODFLT	15037	No Default Queue Defined
PBSE_NORERUN	15038	Job Not Rerunnable
PBSE_ROUTEREJ	15039	Route rejected by all destinations
PBSE_ROUTEEXPD	15040	Time in Route Queue Expired
PBSE_MOMREJECT	15041	Request to MoM failed
PBSE_BADSCRIPT	15042	(qsub) Cannot access script file
PBSE_STAGEIN	15043	Stage In of files failed
PBSE_RESCUNAV	15044	Resources temporarily unavailable
PBSE_BADGRP	15045	Bad Group specified
PBSE_MAXQUED	15046	Max number of jobs in queue
PBSE_CKPBSY	15047	Checkpoint Busy, may be retries
PBSE_EXLIMIT	15048	Limit exceeds allowable
PBSE_BADACCT	15049	Bad Account attribute value
PBSE_ALRDYEXIT	15050	Job already in exit state

Table 14-1: Error Codes

Error Name	Error Code	Description
PBSE_NOCOPYFILE	15051	Job files not copied
PBSE_CLEANEDOUT	15052	Unknown job id after clean init
PBSE_NOSYNCMSTR	15053	No Master in Sync Set
PBSE_BADDEPEND	15054	Invalid dependency
PBSE_DUPLIST	15055	Duplicate entry in List
PBSE_DISPROTO	15056	Bad DIS based Request Protocol
PBSE_EXECTHERE (**Obsolete**)	15057	Cannot execute there (Obsolete; no longer used.)
PBSE_SISREJECT	15058	Sister rejected
PBSE_SISCOMM	15059	Sister could not communicate
PBSE_SVRDOWN	15060	Request rejected -server shutting down
PBSE_CKPSHORT	15061	Not all tasks could checkpoint
PBSE_UNKNODE	15062	Named vnode is not in the list
PBSE_UNKNODEATR	15063	Vnode attribute not recognized
PBSE_NONODES	15064	Server has no vnode list
PBSE_NODENBIG	15065	Node name is too big
PBSE_NODEEXIST	15066	Node name already exists
PBSE_BADNDATVAL	15067	Bad vnode attribute value
PBSE_MUTUALEX	15068	State values are mutually exclusive
PBSE_GMODERR	15069	Error(s) during global mod of vnodes
PBSE_NORELYMOM	15070	Could not contact MoM
PBSE_REV_NO_WALLTIME	15075	Reservation lacks walltime
Reserved	15076	Not used.
PBSE_TOOLATE	15077	Reservation submitted with a start time that has already passed
PBSE_IRESVE	15078	Internal reservation system error
PBSE_UNKRESVTYPE	15079	Unknown reservation type
PBSE_RESVEXIST	15080	Reservation already exists
PBSE_resvFail	15081	Reservation failed
PBSE_genBatchReq	15082	Batch request generation failed
PBSE_mgrBatchReq	15083	`qmgr` batch request failed
PBSE_UNKRESVID	15084	Unknown reservation ID
PBSE_delProgress	15085	Delete already in progress

Table 14-1: Error Codes

Error Name	Error Code	Description
PBSE_BADTSPEC	15086	Bad time specification(s)
PBSE_RESVMSG	15087	So reply_text can return a msg
PBSE_BADNODESPEC	15089	Node(s) specification error
PBSE_LICENSEINV	15091	License is invalid
PBSE_RESVAUTH_H	15092	Host not authorized to make AR
PBSE_RESVAUTH_G	15093	Group not authorized to make AR
PBSE_RESVAUTH_U	15094	User not authorized to make AR
PBSE_R_UID	15095	Bad effective UID for reservation
PBSE_R_GID	15096	Bad effective GID for reservation
PBSE_IBMSPSWITCH	15097	IBM SP Switch error
PBSE_NOSCHEDULER	15099	Unable to contact scheduler
PBSE_RESCNOTSTR	15100	Resource is not of type string
PBSE_MaxArraySize	15107	max array size exceeded
PBSE_INVALSELECTRESC	15108	resource invalid in select spec
PBSE_INVALJOBRESC	15109	invalid job resource
PBSE_INVALNODEPLACE	15110	node invalid w/place|select
PBSE_PLACENOSELECT	15111	cannot have place w/o select
PBSE_INDIRECTHOP	15112	too many indirect resource levels
PBSE_INDIRECTBT	15113	target resource undefined
PBSE_NGBLUEGENE	15114	No node_group_enable on BlueGene
PBSE_NODESTALE	15115	Cannot change state of stale vnode
PBSE_DUPRESC	15116	cannot dupe resource within a chunk
PBSE_CONNFULL	15117	server connection table full
PBSE_LICENSE_MIN_BADVAL	15118	bad value for pbs_license_min
PBSE_LICENSE_MAX_BADVAL	15119	bad value for pbs_license_max
PBSE_LICENSE_LINGER_BADVAL	15120	bad value for pbs_license_linger_time
PBSE_LICENSE_BAD_ACTION	15122	Not allowed action with licensing
PBSE_BAD_FORMULA	15123	invalid sort formula
PBSE_BAD_FORMULA_KW	15124	invalid keyword in formula
PBSE_BAD_FORMULA_TYPE	15125	invalid resource type in formula
PBSE_BAD_RRULE_YEARLY	15126	reservation duration exceeds 1 year
PBSE_BAD_RRULE_MONTHLY	15127	reservation duration exceeds 1 month

Table 14-1: Error Codes

Error Name	Error Code	Description
PBSE_BAD_RRULE_WEEKLY	15128	reservation duration exceeds 1 week
PBSE_BAD_RRULE_DAILY	15129	reservation duration exceeds 1 day
PBSE_BAD_RRULE_HOURLY	15130	reservation duration exceeds 1 hour
PBSE_BAD_RRULE_MINUTELY	15131	reservation duration exceeds 1 minute
PBSE_BAD_RRULE_SECONDLY	15132	reservation duration exceeds 1 second
PBSE_BAD_RRULE_SYNTAX	15133	invalid recurrence rule syntax
PBSE_BAD_RRULE_SYNTAX2	15134	invalid recurrence rule syntax
PBSE_BAD_ICAL_TZ	15135	Undefined timezone info directory
PBSE_HOOKERROR	15136	error encountered related to hooks
PBSE_NEEDQUET	15137	need queue type set
PBSE_ETEERROR	15138	not allowed to alter attribute when eligible_time_enable is off
PBSE_HISTJOBID	15139	History job ID
PBSE_JOBHISTNOTSET	15140	job_history_enable not SET
PBSE_MIXENTLIMS	15141	mixing old and new limit enforcement
PBSE_HEADERROR	15145	Server host not allowed to be provisioned
PBSE_NODEPROV_NOACTION	15146	While provisioning, provisioning attributes can't be modified
PBSE_NODEPROV	15147	State of provisioning vnode can't be changed
PBSE_NODEPROV_NODEL	15148	Vnode can't be deleted while provisioning
PBSE_NODE_BAD_CURRENT_AOE	15149	Attempt to set an AOE that is not in resources_available.aoe
PBSE_NOTLOCALNODE	15150	Non-local node not allowed in Personal Mode (not used)
PBSE_MOM_INCOMPLETE_HOOK	15167	Execution hooks not fully transferred to a particular MoM
PBSE_MOM_REJECT_ROOT_SCRIPTS	15168	A MoM has rejected a request to copy a hook-related file, or a job script to be executed by root
PBSE_HOOK_REJECT	15169	A MoM received a reject result from a mom hook
PBSE_HOOK_REJECT_RERUNJOB	15170	Hook rejection requiring a job to be rerun
PBSE_HOOK_REJECT_DELETEJOB	15171	Hook rejection requiring a job to be deleted
PBSE_JOBNBIG	15173	Submitted job or reservation name is too long
	15178	Cannot alter start time of running, non-empty reservation
	15179	Cannot alter current or next occurrence of a standing reservation so that it interferes with a later occurrence
Resource monitor specific error codes		
PBSE_RMUNKNOWN	15201	Resource unknown

Table 14-1: Error Codes

Error Name	Error Code	Description
PBSE_RMBADPARAM	15202	Parameter could not be used
PBSE_RMNOPARAM	15203	A needed parameter did not exist
PBSE_RMEXIST	15204	Something specified didn't exist
PBSE_RMSYSTEM	15205	A system error occurred
PBSE_RMPART	15206	Only part of reservation made
PBSE_SSIGNON_BAD_TRANSITION2	15207	bad attempt: false to true
PBSE_TRYAGAIN	15208	Try the request again later
PBSE_ALPSRELERR	15209	PBS is unable to release the ALPS reservation
PBSE_NOTARRAY_ATTR	15231	Attempt to set max_run_subjobs for a non-array job

15
Request Codes

When reading the PBS event logfiles, you may see messages of the form "Type 19 request received from PBS_Server...". These "type codes" correspond to different PBS batch requests. The following table lists all the PBS type codes and the corresponding request of each.

Table 15-1: Request Codes

Numeric Value	Name
0	PBS_BATCH_Connect
1	PBS_BATCH_QueueJob
2	UNUSED
3	PBS_BATCH_jobscript

16
PBS Environment Variables

The following table lists the PBS environment variables:

Table 16-1: PBS Environment Variables

Variable	Origin	Meaning
CONTAINER_IMAGE	Job submitter	Name of container image in which job is to run
NCPUS		Number of threads, defaulting to number of CPUs, on the vnode
NEC_PROCESS_DIST	Job submitter	For NEC SX-Aurora TSUBASA. Specifies process distribution. See "Specifying Process Distribution", on page 208 of the PBS Professional User's Guide.
OMP_NUM_THREADS		Same as NCPUS.
PBS_ARRAY_ID	Server	Identifier for job arrays. Consists of sequence number.
PBS_ARRAY_INDEX	Server	Index number of subjob in job array.
PBS_CONF_FILE		Path to `pbs.conf`
PBS_CONTAINER_ARGS	Job submitter	Arguments to pass to container engine. Multiple arguments are separated with a semicolon. When using this environment variable, the `-env` and `--entrypoint` arguments to `docker run` are not supported. To pass environment variables directly to PBS, use `qsub -v`.
PBS_DEFAULT		Name of default PBS server
PBS_DATA_SERVICE_USER	Admin, during installation	Account used by data service.
PBS_ENVIRONMENT		Indicates job type: *PBS_BATCH* or *PBS_INTERACTIVE*
PBS_JOBCOOKIE		Unique identifier for inter-MoM job-based communication.
PBS_JOBDIR		Pathname of job-specific staging and execution directory
PBS_JOBID	Server	The job identifier assigned to the job or job array by the batch system.
PBS_JOBNAME	User	The job name supplied by the user.
PBS_LICENSE_INFO	Admin	Location of license server

Table 16-1: PBS Environment Variables

Variable	Origin	Meaning
PBS_LOG_HIGHRES_TIMESTAMP		Controls whether daemons on this host log timestamps in microseconds. Default timestamp log format is *HH:MM:SS*. With microsecond logging, format is *HH:MM:SS:XXXXXX*. Does not affect accounting log. Not applicable when using `syslog`. Overrides configuration parameter in `pbs.conf` of the same name. Valid values: *0*, *1*. Default: *0* (no microsecond logging)
PBS_MOMPORT		Port number on which this job's MoMs will communicate.
PBS_NODEFILE		The filename containing a list of vnodes assigned to the job.
PBS_NODENUM		Index into $PBS_NODEFILE. Starts at zero.
PBS_O_HOME	Submission environment	Value of HOME from submission environment.
PBS_O_HOST	Submission environment; set by PBS	The host name on which the `qsub` command was executed.
PBS_O_LANG	Submission environment	Value of LANG from submission environment
PBS_O_LOGNAME	Submission environment	Value of LOGNAME from submission environment
PBS_O_MAIL	Submission environment	Value of MAIL from submission environment
PBS_O_PATH	Submission environment	Value of PATH from submission environment
PBS_O_QUEUE	Submission environment	The original queue name to which the job was submitted.
PBS_O_SHELL	Submission environment	Value of SHELL from submission environment
PBS_O_SYSTEM	Submission environment	The operating system name where `qsub` was executed.
PBS_O_TZ	Submission environment	Value of TZ from submission environment
PBS_O_WORKDIR	Submission environment	The absolute path of directory where `qsub` was executed.
PBS_QUEUE		The name of the queue from which the job is executed.
PBS_SCHED_THREADS		Maximum number of scheduler threads. Scheduler automatically caps number of threads at the number of cores (or hyperthreads if applicable), regardless of value of this variable. Overridden by `pbs_sched -t` option. Overrides PBS_SCHED_THREADS parameter in `pbs.conf`. Default: 1
PBS_SERVER	Submission environment	The name of the default PBS server.
PBS_SID		Session ID

Table 16-1: PBS Environment Variables

Variable	Origin	Meaning
PBS_TASKNUM		The task (process) number for the job on this vnode.
PBS_TMPDIR		Root of temporary directories/files for PBS components.
TMPDIR		The job-specific temporary directory for this job.

17
File Listing

The following table lists all the PBS files and directories; owner and permissions are specific to Linux systems.

Table 17-1: File Listing

Directory / File	Owner	Permission	Average Size
/opt/pbs/default/etc/pbs_bootcheck.py	root	-rw-r--r--	4111
/var/tmp/pbs_bootcheck.py	root	-rw-r--r--	4111
/var/tmp/pbs_boot_check See "Discovering Last Reboot Time of Server" on page 438 in the PBS Professional Administrator's Guide.	root	-rw-r--r--	188
PBS_EXEC/	root	drwxr-xr-x	4096
PBS_EXEC/bin	root	drwxr-xr-x	4096
PBS_EXEC/bin/pbsdsh	root	-rwxr-xr-x	111837
PBS_EXEC/bin/pbsnodes	root	-rwxr-xr-x	153004
PBS_EXEC/bin/pbs_dataservice	root	-rwx------	
PBS_EXEC/bin/pbs_hostn	root	-rwxr-xr-x	35493
PBS_EXEC/bin/pbs_rdel	root	-rwxr-xr-x	151973
PBS_EXEC/bin/pbs_rstat	root	-rwxr-xr-x	156884
PBS_EXEC/bin/pbs_rsub	root	-rwxr-xr-x	167446
PBS_EXEC/bin/pbs_tclsh	root	-rwxr-xr-x	857552
PBS_EXEC/bin/pbs_wish	root	-rwxr-xr-x	1592236

18 Introduction to PBS

18.1 Acknowledgements

PBS Professional is the enhanced commercial version of the PBS software originally developed for NASA. The NASA version had a number of corporate and individual contributors over the years, for which the PBS developers and PBS community is most grateful. Below we provide formal legal acknowledgements to corporate and government entities, then special thanks to individuals.

The NASA version of PBS contained software developed by NASA Ames Research Center, Lawrence Livermore National Laboratory, and MRJ Technology Solutions. In addition, it included software developed by the NetBSD Foundation, Inc., and its contributors as well as software developed by the University of California, Berkeley and its contributors.

Other contributors to the NASA version of PBS include Bruce Kelly and Clark Streeter of NERSC; Kent Crispin and Terry Heidelberg of LLNL; John Kochmar and Rob Pennington of Pittsburgh Supercomputing Center; and Dirk Grunwald of University of Colorado, Boulder. The ports of PBS to the Cray T3e and the IBM SP SMP were funded by DoD USAERDC; the port of PBS to the Cray SV1 was funded by DoD MSIC.

No list of acknowledgements for PBS would possibly be complete without special recognition of the first two beta test sites. Thomas Milliman of the Space Sciences Center of the University of New Hampshire was the first beta tester. Wendy Lin of Purdue University was the second beta tester and holds the honor of submitting more problem reports than anyone else outside of NASA.

Contents

1 Getting Started with PBS

1.1 Why Use PBS?

PBS frees you from the mechanics of getting your work done; you don't need to shepherd each job to the right machine, get input and output copied back and forth, or wait until a particular machine is available. You need only specify requirements for the tasks you want executed, and hand the tasks off to PBS. PBS holds each task until a slot opens up, then takes care of copying input files to the execution directory, executing the task, and returning the output to you.

PBS keeps track of which hardware is available, and all waiting and running tasks. PBS matches the requirements of each of your tasks to the right hardware and time slot, and makes sure that tasks are run according to the site's policy. PBS also maximizes usage and throughput.

1.2 PBS Tasks and Components

1.2.1 PBS Tasks

PBS is a distributed workload management system. PBS manages and monitors the computational workload for one or more computers. PBS does the following:

Queuing jobs

PBS collects jobs (work or tasks) to be run on one or more computers. Users submit jobs to PBS, where they are queued up until PBS is ready to run them.

Scheduling jobs

PBS selects which jobs to run, and when and where to run them, according to the resources requested by the job, and the policy specified by the site administrator. PBS allows the administrator to prioritize jobs and allocate resources in a wide variety of ways, to maximize efficiency and/or throughput.

Monitoring jobs

PBS tracks system resources, enforces usage policy, and reports usage. PBS tracks job completion, ensuring that jobs run despite system outages.

Returning Output

PBS returns job output to the location you specify. See Chapter 3, "Job Input & Output Files", on page 33.

1.2.2 PBS Components and Process

PBS consists of a set of commands and system daemons/services for running jobs:

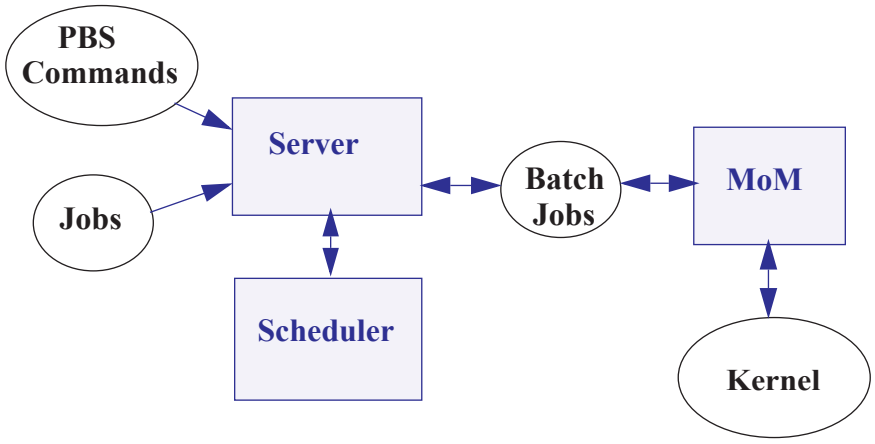

Figure 1-1: Jobs are submitted to the PBS server. The scheduler chooses where and when to run the jobs, and the server sends the jobs to MoM. PBS commands communicate with the server.

The server and scheduler daemons run on the server host. A machine that executes jobs is called an execution host. Each execution host runs a MoM daemon. The server host can run a MoM daemon. One server manages any number of MoM daemons. Communication between daemons is handled by communication daemons. Commands can be run from the server host, execution hosts, and command-only client hosts. The server/scheduler/communication host, the execution hosts, and the client hosts are called a *PBS complex*.

Commands

PBS provides a set of commands that you can use to submit, monitor, alter, and delete jobs. The PBS commands can be installed on any supported platform, with or without the other PBS components.

Some PBS commands or command options can be run by any PBS user, while some require elevated privilege.

Job

A PBS job is a task, in the form of a shell script, `cmd` batch file, Python script, etc. describing the commands and/or applications you want to run. You hand your task off to PBS, where it becomes a PBS job.

Server

The PBS server manages jobs for the PBS complex. PBS commands talk to the PBS server, jobs are submitted to the server, and the server queues the jobs and sends them to execution hosts.

Scheduler

The scheduler runs jobs according to the policy specified by the site administrator. The scheduler matches each job's requirements with available resources, and prioritizes jobs and allocates resources according to policy.

MoM

A MoM manages jobs once they are sent to its execution host. One MoM manages the jobs on each execution host. The MoM stages files in, runs any prologue, starts each job, monitors the job, stages files out and returns output to the job submitter, runs any epilogue, and cleans up after the job. The MoM can also run any execution host hooks.

MoM creates a new session that is as identical to your login session as is possible. For example, under Linux, if the job submitter's login shell is `csh`, then MoM creates a session in which `.login` is run as well as `.cshrc`.

MoM is a reverse-engineered acronym that stands for Machine-oriented Mini-server.

Communication daemon

The *communication daemon*, pbs_comm, handles communication between the other PBS daemons.

1.3 Interfaces to PBS

PBS provides a command-line interface, and Altair offers a web-based front end to PBS called Access, which is a separate product. This document describes the PBS command-line interface. For information on Access, see www.altair.com.

1.3.1 PBS Commands

PBS provides a set of commands that allow you to submit, monitor, and manage your jobs. Some PBS commands can be used by any PBS user; some can be used only by administrators, and some have different behavior depending on the role of the person invoking them. In this document, we describe the commands that can be used by any PBS user. For a complete description of all commands and their requirements, see "List of Commands" on page 22 of the PBS Professional Reference Guide.

Table 1-1: PBS Commands

Command	Action
mpiexec	Runs MPI programs under PBS on Linux
pbsdsh	Distributes tasks to vnodes under PBS
pbsnodes	Queries PBS host or vnode status, marks hosts free or offline, changes the comment for a host, or outputs vnode information
pbs_attach	Attaches a session ID to a PBS job
pbs_hostn	Reports hostname and network address(es)
pbs_login	Caches encrypted user password for authentication
pbs_mpihp	Runs an MPI application in a PBS job with HP MPI
pbs_mpirun	Runs MPI programs under PBS with MPICH
pbs_python	Python interpreter for debugging a hook script from the command line
pbs_ralter	Modifies an existing advance, standing, or job-specific reservation
pbs_rdel	Deletes a PBS advance, standing, or job-specific reservation
pbs_release_nodes	Releases sister hosts or vnodes assigned to a PBS job
pbs_rstat	Shows status of PBS advance, standing, or job-specific reservations
pbs_rsub	Creates a PBS advance, standing, or job-specific reservation
pbs_tclsh	**Deprecated**. TCL shell with TCL-wrapped PBS API
pbs_tmrsh	TM-enabled replacement for rsh/ssh for use by MPI implementations
pbs_wish	**Deprecated**. TK window shell with TCL-wrapped PBS API
qalter	Alters a PBS job
qdel	Deletes PBS jobs

Table 1-1: PBS Commands

Command	Action
qhold	Holds PBS batch jobs
qmgr	Administrator's command interface for managing PBS
qmove	Moves a PBS job from one queue to another
qmsg	Writes message string into one or more job output files
qorder	Swaps queue positions of two PBS jobs
qrls	Releases holds on PBS jobs
qsig	Selects specified PBS jobs
qsig	Sends signal to PBS job
qstat	Displays status of PBS jobs, queues, or servers
qsub	Submits a job to PBS

1.4 Setting Up Your Environment

1.4.1 Prerequisites for Account

Your account must have the following characteristics for PBS to work correctly:

- Account must have access to all PBS hosts
- Account must have valid username and group on all execution hosts and on the server
- Account must be able to transfer files between hosts using the file transfer mechanism chosen by the administrator. This is described in section 9.7, "Setting File Transfer Mechanism", on page 441 of the PBS Professional Administrator's Guide.
- The time zone environment variable must be set correctly in order to use advance and standing reservations. See section 1.4.4, "Setting Time Zone for Submission Host", on page 9.
- Username must be 256 characters or less in length.
- Your environment must be correctly configured:
  - For Linux, see section 1.4.2, "Setting Up Your Linux Environment", on page 5.
  - For Windows, see section 1.4.3, "Setting Up Your Windows Environment", on page 6.
- Account must have correct user authorization to run jobs.
  - For Linux, see section 1.4.2.7, "User Authorization Under Linux", on page 6.
  - For Windows, see section 1.4.3.4, "User Authorization under Windows", on page 7

1.4.2 Setting Up Your Linux Environment

1.4.2.1 Set Paths to PBS Commands

PBS commands reside in a directory pointed to by $PBS_EXEC/bin. This path may change from one installation of PBS to the next, so use the variable instead of the absolute path. The location of $PBS_EXEC is given in /etc/pbs.conf. Make it easy to use PBS commands by doing the following:

1. In your .login file, source /etc/pbs.conf:

   If you are using bash or sh, do the following:

   ```
   % . /etc/pbs.conf
   ```

   If you are using csh, do the following:

   ```
   %source /etc/pbs.conf
   ```

2. Add the path to PBS commands to your PATH environment variable. Use $PBS_EXEC, not the absolute path. For example, where MY_PATH is your existing set of paths:

   ```
   setenv PATH ${MY_PATH}:$PBS_EXEC/bin/
   ```

1.4.2.2 Set Paths to PBS Man Pages

Add the path to the PBS man pages to your MANPATH environment variable:

```
setenv MANPATH /usr/man:/usr/local/man:$PBS_EXEC/share/man/
```

1.4.2.3 Make Login and Logout Files Behave Properly for Jobs

By default, PBS runs your jobs under your login, meaning that your login and logout files are sourced for each job. If your .cshrc, .login, .profile, or .logout contains commands that attempt to set terminal characteristics or produce output, such as by writing to stdout, jobs may not run. Make sure that any such command in these files is skipped when the file is run inside a PBS job. PBS sets the PBS_ENVIRONMENT environment variable inside jobs. Test for the PBS_ENVIRONMENT environment variable and run commands only when it is not set. For example, in a .login file:

```
if ( ! $?PBS_ENVIRONMENT ) then
    do terminal settings here
    run command with output here
endif
```

1.4.2.4 Capture Correct Job Exit Status

When a PBS job runs, the exit status of the last command executed in the job is reported by the job's shell to PBS as the exit status of the job. The exit status of the job is important for job dependencies and job chaining. Under Linux, the last command executed might not be the last command in your job, if you have a .logout on the execution host. In that case, the last command executed is from the .logout and not from your job. To prevent this, preserve the job's exit status in your .logout file by saving it at the top, then doing an explicit exit at the end, as shown below:

```
set EXITVAL = $status
previous contents of .logout here
exit $EXITVAL
```

Under Windows, you do not need to take special steps to preserve the job's exit status.

1.4.2.5 Avoid Background Processes Inside Jobs

Make sure that your login file doesn't run processes in the background when invoked inside a PBS job. If your login file contains a command that runs in the background inside a PBS job, persistent processes can cause trouble.

1.4.2.6 Provide `bash` Functions to Jobs

If your jobs need to have exported bash functions available to them, you can put these functions in your `.profile` or `.login` on the execution host(s). You can also use `qsub -V` or `qsub -v <function name>` to forward the function at job submission. Just make sure that you don't have a function with the same name as an environment variable if you use -v or -V. See section 6.12.4, "Forwarding Exported Shell Functions", on page 129.

1.4.2.7 User Authorization Under Linux

The server's flatuid attribute determines whether it assumes that identical usernames mean identical users. If *True*, it assumes that if User1 exists on both the submission host and the server host, then User1 can run jobs on that server. If not *True*, the server calls `ruserok()` which uses `/etc/hosts.equiv` or `.rhosts` to authorize User1 to run as User1. In this case, the username you specify with the -u option must have a `.rhosts` file on the server host listing the job owner, meaning that User1 at the server must have a `.rhosts` file listing User1.

Table 1-2: Linux User ID and flatuid

Value of flatuid	Submission Host Username vs. Server Host Username	
	User1 Same as User1	User1 Different from UserA
True	Server assumes user has permission to run job	Server checks whether User1 can run job as UserA
False/unset	Server checks whether User1 can run job as User1	Server checks whether User1 can run job as UserA

Example 1-1: Our user is UserA on the submission host, but is userB at the server. In order to submit jobs as UserA and run jobs as UserB, UserB must have a `.rhosts` file on the server host that lists UserA

Note that if different names are listed via the -u option, then they are checked regardless of the value of `flatuid`.

Using `hosts.equiv` is not recommended.

1.4.2.8 Submitting Linux Jobs from Linux Clients

If the authentication method at a Linux client host has been set to pwd, set it to munge before you submit a Linux job. For example:

```
export PBS_AUTH_METHOD=munge; qsub -lselect=1:arch=linux -- sleep 100
```

1.4.3 Setting Up Your Windows Environment

1.4.3.1 HOMEDIR for Windows Users

PBS starts jobs in the job owner's home directory, which is pointed to by `HOMEDIR`.

If you have not been explicitly assigned a home directory, PBS uses a Windows-assigned default as the base location for your default home directory, and starts jobs there. Windows assigns the following default home path:

```
[PROFILE_PATH]\My Documents\PBS Pro
```

For example, if userA has not been assigned a home directory, the default home directory is the following:

```
\Documents and Settings\userA\My Documents\PBS Pro
```

Windows can return one PROFILE_PATH in one of the following forms:

```
\Documents and Settings\username
\Documents and Settings\username.local-hostname
\Documents and Settings\username.local-hostname.00N
```

where *N* is a number

```
\Documents and Settings\username.domain-name
```

1.4.3.2 Requirements for Windows Username

- The username must contain only alphanumeric characters, dot (.), underscore (_), and/or hyphen "-".
- The hyphen must not be the first letter of the username.
- If "@" appears in the username, then it is assumed to be in the context of a Windows domain account: `username@domainname`.
- The space character is allowed. If a space character appears in a username string, then the string is displayed in quotes, and must be specified in quotes.

1.4.3.3 Requirements for Windows User Account

Your Windows user account must be a normal user account. You cannot submit jobs from a SYSTEM account.

1.4.3.4 User Authorization under Windows

PBS runs your jobs under your account. When your job runs on a remote execution host, it needs to be able to log in and transfer files using your account. If your system administrator has not set up access using `hosts.equiv`, you can set up access using `.rhosts` files. A `.rhosts` file on the server allows you to submit jobs from a remote machine to the server.

Set up the `.rhosts` file in your PROFILE_PATH, in your home directory, on the PBS server host and on each execution host. For example:

```
\Documents and Settings\username\.rhosts
```

Format of `.rhosts` file:

hostname username

Be sure the `.rhosts` file is owned by you or an administrator-type group, and has write access granted only to you or an administrator or group.

Add all PBS hosts to your `.rhosts` file:

```
Host1 user1
Host2 user1
Host3 user1
```

Make sure that you list all the names by which a host may be known. For instance, if Host4 is known as "Host4", "Host4.<subdomain>", or "Host4.<subdomain>.<domain>" you should list all three in the `.rhosts` file:

```
Host4 user1
Host4.subdomain user1
Host4.subdomain.domain user1
```

If your username contains white space, quote it in the .rhosts file:

```
Host4.subdomain.domain "Bob Jones"
```

Example 1-2: The following entry in user user1's .rhosts file on the server permits user user1 to run jobs submitted from the workstation wks031:

```
wks031 user1
```

To allow user1's output files from a job that runs on execution host Host1 to be returned to user1 automatically by PBS, user1 adds an entry to the .rhosts file on the workstation naming the execution host Host1:

```
Host1 user1
```

1.4.3.5 Set up Paths

If you will use a mapped drive for submitting jobs, staging files in and out, or for output and error files, you must map that drive with a local system account. We recommend using UNC paths. If you do not use a local system account, file transfer behavior is undefined. To map a drive with global access using a local system account, use the psExec utility from SysInternals:

<path to psexec binary> -s net use <mapped drive letter>: <UNC path to map>

For example:

```
psexec -s net use Z: \\examplehost\mapping_directory\mydirectory
```

To unmap a mapped drive:

<path to psexec binary> -s net use /delete <mapped drive letter>

For example:

```
psexec -s net use /delete Z:
```

PBS requires that your username be consistent across a server and its execution hosts, but not across a submission host and a server. You may have access to more than one server, and may have a different username on each server. You can change the user ID for a job; see section 2.5.4, “Specifying Job Username”, on page 28.

1.4.3.6 Password for Job Submission Authentication

Run the pbs_login command whenever your password changes. The new password is used for any job that is not already running.

1.4.3.6.i Setting Password at Windows Clients

Run the pbs_login command once for each Windows submission host, so that you can submit jobs and run PBS client commands.

```
echo <password>| pbs_login -p
```

Test whether you can run client commands:

```
qstat -Bf
```

The new password is used for any job that is not already running.

1.4.3.6.ii Setting Password at Linux Clients

Run the pbs_login command at any Linux client host where you want to submit a Windows job. Set PBS_AUTH_METHOD to *pwd*:

```
export PBS_AUTH_METHOD=pwd; pbs_login
```

1.4.3.7 Authentication for Client Commands

You can run all client commands except `qsub` using either pwd or munge as the authentication method, so you don't need to make any changes for commands such as `qstat`, etc.

1.4.4 Setting Time Zone for Submission Host

Make sure that the environment variable PBS_TZID is set correctly at your submission host. Set this environment variable to a timezone location known to PBS Professional. You can get the appropriate zone location from the PBS server host.

On Linux, use the `tzselect` command if it is available, or get the zone location from `/usr/share/zoneinfo/zone.tab`.

On all other platforms, use the list of `libical` supported zoneinfo locations available under `$PBS_EXEC/lib/ical/zoneinfo/zones.tab`.

The format for PBS_TZID is a timezone location, rather than a timezone POSIX abbreviation. Examples of values for PBS_TZID are:

```
America/Los_Angeles
America/Detroit
Europe/Berlin
Asia/Calcutta
```

2
Submitting a PBS Job

2.1 Introduction to the PBS Job

To use PBS, you create a *batch job*, usually just called a *job,* which you then hand off, or *submit*, to PBS. A batch job is a set of commands and/or applications you want to run on one or more execution machines, contained in a file or typed at the command line. You can include instructions which specify the characteristics such as job name and resource requirements such as memory, CPU time, etc., that your job needs. The job file can be a shell script under Linux, a `cmd` batch file under Windows, a Python script, a Perl script, etc.

For example, here is a simple PBS batch job file which requests one hour of time, 400MB of memory, 4 CPUs, and runs `my_application`:

```
#!/bin/sh
#PBS -l walltime=1:00:00
#PBS -l mem=400mb,ncpus=4
./my_application
```

To submit the job to PBS, you use the `qsub` command, and give the job script as an argument to `qsub`. For example, to submit the script named "`my_script`":

```
qsub my_script
```

We will go into the details of job script creation in section 2.2, “The PBS Job Script”, on page 14, and job submission in section 2.3, “Submitting a PBS Job”, on page 19.

2.1.1 Lifecycle of a PBS Job, Briefly

Your PBS job has the following lifecycle:

1. You write a job script
2. You submit the job to PBS
3. PBS accepts the job and returns a job ID to you
4. The PBS scheduler finds the right place and time to run your job, and sends your job to the selected execution host(s)
5. Application licenses are checked out
6. On each execution host, if specified, PBS creates a job-specific staging and execution directory
7. PBS sets PBS_JOBDIR and the job's jobdir attribute to the path of the job's staging and execution directory.
8. On each execution host allocated to the job, PBS creates a temporary scratch directory.
9. PBS sets the TMPDIR environment variable to the pathname of the temporary directory.
10. If any errors occur during directory creation or the setting of variables, the job is requeued.
11. Input files or directories are copied to the primary execution host

- If it exists, the prologue runs on the primary execution host, with its current working directory set to `PBS_HOME/mom_priv`, and with PBS_JOBDIR and TMPDIR set in its environment.

12. The job is run as you on the primary execution host.
13. The job's associated tasks are run as you on the execution host(s).
14. If it exists, the epilogue runs on the primary execution host, with its current working directory set to the path of the job's staging and execution directory, and with PBS_JOBDIR and TMPDIR set in its environment.
15. Output files or directories are copied to specified locations
16. Temporary files and directories are cleaned up
17. Application licenses are returned to pool

For more detail about the lifecycle of a job, see section 3.2.8, “Detailed Description of Job Lifecycle”, on page 39.

2.1.2 Where and How Your PBS Job Runs

Your PBS jobs run on hosts that the administrator has designated to PBS as execution hosts. The PBS scheduler chooses one or more execution hosts that have the resources that your job requires.

PBS runs your jobs under your user account. This means that your login and logout files are executed for each job, and some of your environment goes with the job. It's important to make sure that your login and logout files don't interfere with your jobs; see section 1.4.2, “Setting Up Your Linux Environment”, on page 5.

2.1.3 The Job Identifier

After you submit a job, PBS returns a *job identifier*. Format for a job:

<sequence number>.<server name>

Format for a job array:

<sequence number>[].<server name>.<domain>

You'll need the job identifier for any actions involving the job, such as checking job status, modifying the job, tracking the job, or deleting the job.

The limit for the largest possible job ID defaults to the 7-digit number 9,999,999, but your administrator may have set it to a larger value. After the largest job ID has been assigned, PBS starts assigning job IDs again at zero.

2.1.4 Shell Script(s) for Your Job

When PBS runs your job, PBS starts the top shell that you specify for the job. The top shell defaults to your login shell on the execution host, but you can set another using the job's Shell_Path_List attribute. See section 2.3.3.1, "Specifying the Top Shell for Your Job", on page 19.

Under Linux, if you do not specify a shell inside the job script, PBS defaults to using `/bin/sh`. If you specify a different shell inside the job script, the top shell spawns that shell to run the script; see section 2.3.3.2, "Specifying Job Script Shell or Interpreter", on page 20.

Under Windows, the job shell is the same as the top shell.

2.1.5 Scratch Space for Jobs

When PBS runs your job, it creates a temporary scratch directory for the job on each execution host. Your administrator can specify a root for the temporary directory on each execution host using the $tmpdir MoM parameter.

PBS removes the directory when the job is finished. The location of the temporary directory is set by PBS; you should not set TMPDIR.

Your job script can access the scratch space. For example:

Linux:

```
cd $TMPDIR
```

Windows:

```
cd %TMPDIR%
```

For scratch space for MPI jobs, see section 5.2.3, "Caveats for Using MPIs", on page 86.

2.1.5.1 Temporary Scratch Space Location Under Linux

If your administrator has not specified a temporary directory, the root of the temporary directory is `/var/tmp`. PBS sets the TMPDIR environment variable to the full path to the temporary scratch directory.

2.1.5.2 Temporary Scratch Space Location Under Windows

Under Windows, PBS creates the temporary directory and sets TMP to the value of the Windows %TMPDIR% environment variable. If your administrator has not specified a temporary directory, PBS creates the temporary directory under either `\winnt\temp` or `\windows\temp`.

2.1.6 Types of Jobs

PBS allows you to submit standard batch jobs or *interactive* jobs. The difference is that while the interactive job runs, you have an interactive session running, giving you interactive access to job processes. There is no interactive access to a standard batch job. We cover interactive jobs in section 6.11, "Running Your Job Interactively", on page 123.

2.1.7 Job Input and Output Files

You can tell PBS to copy files or directories from any accessible location to the execution host, and to copy output files and directories from the execution host wherever you want. We describe how to do this in Chapter 3, "Job Input & Output Files", on page 33.

2.2 The PBS Job Script

2.2.1 Overview of a Job Script

A PBS job script consists of:

- An optional shell specification
- PBS directives
- Job tasks (programs or commands)

2.2.2 Types of Job Scripts

PBS allows you to use any of the following for job scripts:

- A Python, Perl, or other script that can run under Windows or Linux
- A shell script that runs under Linux
- Windows command or PowerShell batch script under Windows

2.2.2.1 Linux Shell Scripts

Since the job file can be a shell script, the first line of a shell script job file specifies which shell to use to execute the script. Your login shell is the default, but you can change this. This first line can be omitted if it is acceptable for the job file to be interpreted using the login shell. We recommend that you always specify the shell.

2.2.2.2 Python Job Scripts

PBS allows you to submit jobs using Python scripts under Windows or Linux. PBS includes a Python package, allowing Python job scripts to run; you do not need to install Python. To run a Python job script:

Linux:

```
qsub <script name>
```

Windows:

```
qsub -S %PBS_EXEC%\bin\pbs_python.exe <script name>
```

If the path contains any spaces, it must be quoted, for example:

```
qsub -S "%PBS_EXEC%\bin\pbs_python.exe" <python job script>
```

You can include PBS directives in a Python job script as you would in a Linux shell script. For example:

```
% cat myjob.py
#!/usr/bin/python
#PBS -l select=1:ncpus=3:mem=1gb
#PBS -N HelloJob
print "Hello"
```

Python job scripts can access Win32 APIs, including the following modules:

- Win32api
- Win32con
- Pywintypes

2.2.2.2.i Debugging Python Job Scripts

You can run Python interactively, outside of PBS, to debug a Python job script. You use the Python interpreter to test parts of your script.

Under Linux, use the -i option to the `pbs_python` command, for example:

```
/opt/pbs/bin/pbs_python -i <return>
```

Under Windows, the `-i` option is not necessary, but can be used. For example, either of the following will work:

```
C:\Program Files\PBS\exec\bin\pbs_python.exe <return>
C:\Program Files\PBS\exec\bin\pbs_python.exe -i <return>
```

When the Python interpreter runs, it presents you with its own prompt. For example:

```
% /opt/pbs/bin/pbs_python -i <return>
>> print "hello"
hello
```

2.2.2.2.ii Python Windows Caveats

- If you have Python natively installed, and you need to use the `win32api`, make sure that you import `pywintypes` before `win32api`, otherwise you will get an error. Do the following:

  ```
  cmd> pbs_python
  >> import pywintypes
  >> import win32api
  ```

- Make sure you specify Windows as the architecture when you submit a Windows job. When you create a selection statement that describes the resources your job needs, include the architecture for each chunk. We describe selection statements in Chapter 4, "Allocating Resources & Placing Jobs", on page 51. For example:

  ```
  #PBS -l select=ncpus=2:mem=1gb:arch=windows
  ```

  Note that "windows" is case-sensitive here.

2.2.2.3 Windows Job Scripts

The Windows script can be a `.exe` or `.bat` file, or a Python or Perl script.

2.2.2.3.i Requirements for Windows Command Scripts

- Make sure you specify Windows as the architecture when you submit a Windows job. When you create a selection statement that describes the resources your job needs, include the architecture for each chunk. We describe selection statements in Chapter 4, "Allocating Resources & Placing Jobs", on page 51. For example:

  ```
  #PBS -l select=ncpus=2:mem=1gb:arch=windows
  ```

  Note that "windows" is case-sensitive here.

- Under Windows, comments in the job script must be in ASCII characters.
- Any `.bat` files that are to be executed within a PBS job script have to be prefixed with "`call`" as in:

  ```
  @echo off
  call E:\step1.bat
  call E:\step2.bat
  ```

Without the "`call`", only the first `.bat` file gets executed and it doesn't return control to the calling interpreter.

For example, an old job script that contains:

```
@echo off
E:\step1.bat
E:\step2.bat
```

should now be:

```
@echo off
call E:\step1.bat
call E:\step2.bat
```

2.2.2.3.ii Windows Advice and Caveats

- In Windows, if you use `notepad` to create a job script, the last line is not automatically newline-terminated. Be sure to add one explicitly, otherwise, PBS job will get the following error message:

  `More?`

  when the Windows command interpreter tries to execute that last line.
- Drive mapping commands are typically put in the job script.
- Do not use `xcopy` inside a job script. Use `copy`, `robocopy`, or `pbs_rcp` instead. The `xcopy` command sometimes expects input from the user. Because of this, it must be assigned an input handle. Since PBS does not create the job process with an input handle assigned, `xcopy` can fail or behave abnormally if used inside a PBS job script.
- PBS jobs submitted from `cygwin` execute under the native `cmd` environment, and not under `cygwin`.

2.2.3 Setting Job Characteristics

2.2.3.1 Job Attributes

PBS represents the characteristics of a job as *attributes*. For example, the name of a job is an attribute of that job, stored in the value of the job's Job_Name attribute. Some job attributes can be set by you, some can be set only by administrators, and some are set only by PBS. For a complete list of PBS job attributes, see "Job Attributes" on page 327 of the PBS Professional Reference Guide. Job attributes are case-insensitive.

2.2.3.2 Job Resources

PBS represents the things that a job might use as *resources*. For example, the number of CPUs and the amount of memory on an execution host are resources. PBS comes with a set of built-in resources, and your PBS administrator can define resources. You can see a list of all built-in PBS resources in Chapter 5, "List of Built-in Resources", on page 259. Resources are case-insensitive.

2.2.3.3 Setting Job Attributes

You can set job attributes and request resources using the following equivalent methods:

- Using specific options to the `qsub` command at the command line; for example, `-e <path>` to set the error path.
- Using PBS directives in the job script; for example, `#PBS -WError_Path=<path>` to set the error path.

These methods have the same functionality. If you give conflicting options to `qsub`, the last option specified overrides any others. Options to the `qsub` command override PBS directives, which override defaults. Some job attributes and resources have default values; your administrator can set default values for some attributes and resources.

After the job is submitted, you can use the `qalter` command to change the job's characteristics.

2.2.3.4 Using PBS Directives

You can use PBS directives to set the values of job attributes. A directive has the directive prefix as the first non-whitespace characters. The default for the prefix is *#PBS*.

Put all your PBS directives at the top of the script file, above any commands. Any directive after an executable line in the script is ignored. For example, if your script contains "`@echo`", put that line below all PBS directives.

2.2.3.4.i Changing the Directive Prefix

By default, the text string "*#PBS*" is used by PBS to determine which lines in the job file are PBS directives. The leading "`#`" symbol was chosen because it is a comment delimiter to all shell scripting languages in common use on Linux systems. Because directives look like comments, the scripting language ignores them.

Under Windows, however, the command interpreter does not recognize the '`#`' symbol as a comment, and will generate a benign, non-fatal warning when it encounters each "*#PBS*" string. While it does not cause a problem for the batch job, it can be annoying or disconcerting to you. If you use Windows, you may wish to specify a different PBS directive, via either the PBS_DPREFIX environment variable, or the "`-C`" option to `qsub`. The `qsub` option overrides the environment variable. For example, we can direct PBS to use the string "*REM PBS*" instead of "*#PBS*" and use this directive string in our job script:

```
REM PBS -l walltime=1:00:00
REM PBS -l select=mem=400mb:arch=windows
REM PBS -j oe
date /t
.\my_application
date /t
```

Given the above job script, we can submit it to PBS in one of two ways:

```
set PBS_DPREFIX=REM PBS
qsub my_job_script
```

or

```
qsub -C "REM PBS" my_job_script
```

2.2.3.4.ii Caveats and Restrictions for PBS Directives

- You cannot use *PBS_DPREFIX* as the directive prefix.
- The limit on the length of a directive string is 4096 characters.

2.2.4 Job Tasks

These can be programs or commands. This is where you can specify an application to be run.

2.2.5 Job Script Names

We recommended that you avoid using special characters in job script names. If you must use them, on Linux you must escape them using the backslash ("\") character.

2.2.5.1 How PBS Parses a Job Script

PBS parses a job script in two parts. First, the `qsub` command scans the script looking for directives, and stops at the first executable line it finds. This means that if you want `qsub` to use a directive, it must be above any executable lines. Any directive below the first executable line is ignored. The first executable line is the first line that is not a directive, whose first non-whitespace character is not "#", and is not blank. For information on directives, see section 2.2.3.4, "Using PBS Directives", on page 17.

Second, lines in the script are processed by the job shell. PBS pipes the name of the job script file as input to the top shell, and the top shell executes the job shell, which runs the script. You can specify which shell is the top shell; see section 2.3.3.1, "Specifying the Top Shell for Your Job", on page 19, and, under Linux, which shell you want to run the script in the first executable line of the script; see section 2.3.3.2, "Specifying Job Script Shell or Interpreter", on page 20.

2.2.5.1.i Comparison Between Equivalent Linux and Windows Job Scripts

The following Linux and Windows job scripts produce the same results.

Linux:

```
#!/bin/sh
#PBS -l walltime=1:00:00
#PBS -l select=mem=400mb
#PBS -j oe

date
./my_application
date
```

Windows:

```
REM PBS -l walltime=1:00:00
REM PBS -l select=mem=400mb:arch=windows
REM PBS -j oe

date /t
my_application
date /t
```

The first line in the Windows script does not contain a path to a shell because you cannot specify the path to the shell or interpreter inside a Windows job script. See section 2.3.3.2, "Specifying Job Script Shell or Interpreter", on page 20.

The remaining lines of both files are almost identical. The primary differences are in file and directory path specifications, such as the use of drive letters, and slash vs. backslash as the path separator.

The lines beginning with "`#PBS`" and "`REM PBS`" are PBS directives. PBS reads down the job script until it finds the first line that is not a valid PBS directive, then stops. From there on, the lines in the script are read by the job shell or interpreter. In this case, PBS sees lines 6-8 as commands to be run by the job shell.

In our examples above, the "`-l <resource>=<value>`" lines request specific resources. Here, we request 1 hour of wall-clock time as a job-wide request, and 400 megabytes (MB) of memory in a chunk. If this is a Windows job, we add ":arch=windows" to the chunk description. We will cover requesting resources in Chapter 4, "Allocating Resources & Placing Jobs", on page 51.

The "`-j oe`" line requests that PBS *join* the `stdout` and `stderr` output streams of the job into a single stream. We will cover merging output in "Merging Output and Error Files" on page 45.

The last three lines are the command lines for executing the programs we wish to run. You can specify as many programs, tasks, or job steps as you need.

2.3 Submitting a PBS Job

2.3.1 Prerequisites for Submitting Jobs

Before you submit any jobs, set your environment appropriately. Follow the instructions in section 1.4, "Setting Up Your Environment", on page 4.

2.3.2 Ways to Submit a PBS Job

You can use the `qsub` command to submit a normal or interactive job to PBS:

- You can call `qsub` with a job script; see section 2.3.3, "Submitting a Job Using a Script", on page 19
- You can call `qsub` with an executable and its arguments; see section 2.3.4, "Submitting Jobs by Specifying Executable on Command Line", on page 22
- You can call `qsub` and give keyboard input; see section 2.3.5, "Submitting Jobs Using Keyboard Input", on page 22

You can use an Altair front-end product to submit and monitor jobs; go to www.pbsworks.com.

2.3.3 Submitting a Job Using a Script

You submit a job to PBS using the `qsub` command. For details on `qsub`, see "qsub" on page 216 of the PBS Professional Reference Guide. To submit a PBS job, type the following:

- Linux shell script:
  `qsub <name of shell script>`
- Linux Python or Perl script:
  `qsub <name of Python or Perl job script>`
- Windows command script:
  `qsub <name of job script>`
- Windows Python script:
  `qsub -S %PBS_EXEC%\bin\pbs_python.exe <name of python job script>`

  If the path contains any spaces, it must be quoted, for example:

  `qsub -S "%PBS_EXEC%\bin\pbs_python.exe" <name of python job script>`

2.3.3.1 Specifying the Top Shell for Your Job

You can can specify the path and name of the shell to use as the top shell for your job. The rules for specifying the top shell are different for Linux and Windows; do not skip the following subsections numbered 2.3.3.1.i and 2.3.3.1.ii.

The Shell_Path_List job attribute specifies the top shell; the default is your login shell on the execution host. You can set this attribute using the the following:

- The "`-S <path list>`" option to `qsub`
- The `#PBS -WShell_Path_List=<path list>` PBS directive

The option argument *path list* has this form:

<path>[@<hostname>][,<path>[@<hostname>],...]

You must supply a *path list* if you attempt to set Shell_Path_List, otherwise, you will get an error. You can specify only one path for any host you name. You can specify only one path that doesn't have a corresponding host name.

PBS chooses the path whose host name matches the name of the execution host. If no matching host is found, then PBS chooses the path specified without a host, if one exists.

2.3.3.1.i Specifying Job Top Shell Under Linux

On Linux, the job's top shell is the one MoM starts when she starts your job, and the job shell is the shell or interpreter that runs your job script commands.

Under Linux, you can use any shell such as `csh` or `sh`, by specifying `qsub -S <path>`. You cannot use Perl or Python as your top shell.

Example 2-1: Using `bash`:

```
qsub -S /bin/bash <script name>
```

2.3.3.1.ii Specifying Job Top Shell Under Windows

On Windows, the job shell is the same as the top shell.

Under Windows, you can specify a shell or an interpreter such as Perl or Python, and if your job script is Perl or Python, you must specify the language using an option to `qsub`; you cannot specify it in the job script.

Example 2-2: Running a Python script on Windows:

```
qsub -S "C:\Program Files\PBS\exec\bin\pbs_python.exe" <script name>
```

2.3.3.1.iii Caveats for Specifying Job Top Shell

If you specify a relative path for the top shell, the full path must be available in your PATH environment variable on the execution host(s). We recommend specifying the full path.

2.3.3.2 Specifying Job Script Shell or Interpreter

2.3.3.2.i Specifying Job Script Shell or Interpreter Under Linux

If you don't specify a shell for the job script, it defaults to `/bin/sh`. You can use any shell, and you can use an interpreter such as Perl or Python.

You specify the shell or interpreter in the first line of your job script. The top shell spawns the specified process, and this process runs the job script. For example, to use `/bin/sh` to run the script, use the following as the first line in your job script:

```
#!/bin/sh
```

To use Perl or Python to run your script, use the path to Perl or Python as the first line in your script:

```
#!/usr/bin/perl
```

or

```
#!/usr/bin/python
```

2.3.3.2.ii Specifying Job Script Shell or Interpreter Under Windows

Under Windows, the job shell or interpreter is the same as the top shell or interpreter. You can specify the top/job shell or interpreter, but not a separate job shell or interpreter. To use a non-default shell or interpreter, you must specify it using an option to `qsub`:

qsub -S <path to shell or interpreter> <script name>

2.3.3.3 Examples of Submitting Jobs Using Scripts

Example 2-3: Our job script is named "`myjob`". We can submit it by typing:

```
qsub myjob
```

and then PBS returns the job ID:

```
16387.exampleserver.exampledomain
```

Example 2-4: The following is the contents of the script named "myjob". In it, we name the job "testjob", and run a program called "myprogram":

```
#!/bin/sh
#PBS -N testjob
./myprogram
```

Example 2-5: The simplest way to submit a job is to give the script name as the argument to qsub, and hit return:

```
qsub <job script> <return>
```

If the script contains the following:

```
#!/bin/sh
./myapplication
```

you have simply told PBS to run myapplication.

2.3.3.4 Passing Arguments to Jobs

If you need to pass arguments to a job script, you can do the following:

- Use environment variables in your script, and pass values for the environment variables using -v or -V.

  For example, to use myinfile as the input to a.out, your job script contains the following:

  ```
  #PBS -N myjobname
  a.out < $INFILE
  ```

  You can then use the -V option:

  ```
  qsub -v INFILE=/tmp/myinfile <job script>
  ```

  For example, to use myinfile and mydata as the input to a.out, your job script contains the following:

  ```
  #PBS -N myjobname
  cat $INFILE $INDATA | a.out
  ```

  You can then use the -V option:

  ```
  qsub -v INFILE=/tmp/myinfile, INDATA=/tmp/mydata <job script>
  ```

  You can export the environment variable first:

  ```
  export INFILE=/tmp/myinfile
  qsub -V <job script>
  ```

- Use a here document. For example:

  ```
  qsub [option] [option] ... <return>
  #PBS <directive>
  ./jobscript.sh arg1      <^d>
  152.examplehost
  ```

If you need to pass arguments to a job, you can do any of the following:

- Pipe a shell command to qsub.

  For example, to directly pass myinfile and mydata as the input to a.out, type the following, or make them into a shell script:

  ```
  echo "a.out myinfile mydata" | qsub -l select=...
  ```

For example:

```
echo "jobscript.sh -a arg1 -b arg2" | qsub -l select=...
```

For example, to use an environment variable to pass `myinfile` as the input to `a.out`, type the following, or make them into a shell script:

```
export INFILE=/tmp/myinfile
export INDATA=/tmp/mydata
echo "a.out $INFILE $INDATA" | qsub
```

- Use `qsub --<executable> <arguments to executable>`. See section 2.3.4, "Submitting Jobs by Specifying Executable on Command Line", on page 22.

2.3.4 Submitting Jobs by Specifying Executable on Command Line

You can run a PBS job by specifying an executable and its arguments instead of a job script. When you run `qsub` this way, it runs the *executable* directly. It does not start a shell, so no shell initialization scripts are run, and execution paths and other environment variables are not set. There is not an easy way to run your command in a different directory. You should make sure that environment variables are set correctly, and you will usually have to specify the full path to the command.

To submit a job directly, you specify the executable on the command line:

qsub [<options>] -- <executable> [<arguments to executable>] <return>

For example, to run `myprog` with the arguments `a` and `b`:

```
qsub -- myprog a b <return>
```

To run `myprog` with the arguments `a` and `b`, naming the job *JobA*,

```
qsub -N JobA -- myprog a b <return>
```

To use environment variables you define earlier:

```
export INFILE=/tmp/myinfile
export INDATA=/tmp/mydata
qsub -- a.out $INFILE $INDATA
```

2.3.5 Submitting Jobs Using Keyboard Input

You can specify that `qsub` read input from the keyboard. If you run the `qsub` command, with the resource requests on the command line, and then press "enter" without naming a job file, PBS will read input from the keyboard. (This is often referred to as a "here document".) You can direct `qsub` to stop reading input and submit the job by typing on a line by itself a `control-d` (Linux) or `control-z`, then "enter" (Windows). You get the same behavior with and without a dash operand.

Note that, under Linux, if you enter a `control-c` while `qsub` is reading input, `qsub` will terminate the process and the job will not be submitted. Under Windows, however, often the `control-c` sequence will, depending on the command prompt used, cause `qsub` to submit the job to PBS. In such case, a `control-break` sequence will usually terminate the `qsub` command.

```
qsub [<options>] [-] <return>
    [<directives>]
    [<tasks>]
    ctrl-D
```

2.3.6 Submitting Windows Jobs

Your PBS complex may have all Windows execution and client (submission) hosts, or it may have some Linux and some Windows execution and client hosts. If your complex has some of each execution host, make sure that Windows jobs land on Windows execution hosts, whether you are submitting from Linux or Windows clients.

2.3.6.1 Submitting Windows Jobs from Windows Clients

- If you have not already, run the pbs_login command at each submission host, initially and once for each password change:

  ```
  echo <password>| pbs_login -p
  ```

- When you submit a Windows job from a Windows client, make sure you request a Windows execution host. Request the arch resource set to "windows":

  ```
  qsub -lselect=1:arch=windows
  ```

  Note that "windows" is case-sensitive here.

2.3.6.2 Submitting Windows Jobs from Linux Clients

- If you have not already, run the pbs_login command at any Linux client host where you want to submit a Windows job. Set PBS_AUTH_METHOD to *pwd*:

  ```
  export PBS_AUTH_METHOD=pwd; pbs_login
  ```

- In order to submit a Windows job from a Linux client, specify that the architecture is Windows. The "arch=windows" is case-sensitive. For example:

  ```
  export PBS_AUTH_METHOD=pwd; qsub -lselect=1:arch=windows -- pbs-sleep 100
  ```

2.3.6.3 Submitting Windows and Linux Jobs from Linux Clients

You can submit both Windows and Linux jobs from a Linux client, but you do need to set your authentication method correctly for each kind of job. For example, you can submit a Linux job using MUNGE authentication, then set your authentication method to *pwd* and submit a Windows job:

```
export PBS_AUTH_METHOD=munge; qsub -lselect=1:arch=linux -- pbs-sleep 100
export PBS_AUTH_METHOD=pwd; pbs_login
qsub -lselect=1:arch=windows -- pbs-sleep 100
```

To override the value of the PBS_AUTH_METHOD configuration parameter, set the authentication method in the PBS_AUTH_METHOD environment variable. You can set this in your profile.

2.4 Job Submission Recommendations and Advice

2.4.1 Trapping Signals in Script

You can trap signals in your job script. For example, you can trap preemption and suspension signals.

If you want to trap the signal in your job script, the signal may need to be trapped by all of the job's shells, depending on the signal.

The signal TERM is useful, because it is ignored by shells, but you can trap it and do useful things such as write out status.

Example 2-6: Ignore the listed signals:

```
trap "" 1 2 3 15
```

Example 2-7: Call the function "goodbye" for the listed signals:

```
trap goodbye 1 2 3 15
```

2.5 Job Submission Options

The table below lists the options to the qsub command, and points to an explanation of each:

Table 2-1: Options to the qsub Command

Option	Function and Page Reference
-A <account_string>	"Specifying Accounting String" on page 29
-a <date_time>	"Deferring Execution" on page 121
-C "<directive prefix>"	"Changing the Directive Prefix" on page 17
-c <interval>	"Using Checkpointing" on page 115
-e <path>	"Paths for Output and Error Files" on page 44
-f	"Running qsub in the Foreground" on page 31
-G	"Submitting Interactive GUI Jobs on Windows" on page 127
-h	"Holding and Releasing Jobs" on page 117
-I	"Running Your Job Interactively" on page 123
-J X-Y[:Z]	"Submitting a Job Array" on page 156
-j <join>	"Merging Output and Error Files" on page 45
-k <keep>	"Keeping Output and Error Files on Execution Host" on page 46
-l <resource list>	"Requesting Resources" on page 53
-M <user list>	"Setting Email Recipient List" on page 27
-m <mail options>	"Specifying Email Notification" on page 25
-N <name>	"Specifying Job Name" on page 27
-o <path>	"Paths for Output and Error Files" on page 44
-p <priority>	"Setting Priority for Your Job" on page 122
-P <project>	"Specifying a Project for a Job" on page 27
-q <destination>	"Specifying Server and/or Queue" on page 29
-r <value>	"Allowing Your Job to be Re-run" on page 120
-R <remove options>	"Avoiding Creation of stdout and/or stderr" on page 45
-S <path list>	"Specifying the Top Shell for Your Job" on page 19
-u <user list>	"Specifying Job Username" on page 28

Table 2-1: Options to the `qsub` Command

Option	Function and Page Reference
`-V`	"Exporting All Environment Variables" on page 128
`-v <variable list>`	"Exporting Specific Environment Variables" on page 128
`-W <attribute>=<value>`	"Setting Job Attributes" on page 16
`-W block=true`	"Making qsub Wait Until Job Ends" on page 122
`-W create_resv_from_job=<value>`	"Job-specific Start Reservations" on page 142
`-W depend=<list>`	"Using Job Dependencies" on page 109
`-W group_list=<list>`	"Specifying Job Group ID" on page 28
`-W pwd`	Prompts you for a password
`-W release_nodes_on_stageout=<value>`	"Releasing Unneeded Vnodes from Your Job" on page 129
`-W run_count=<value>`	"Controlling Number of Times Job is Re-run" on page 121
`-W sandbox=<value>`	"Staging and Execution Directory: User Home vs. Job-specific" on page 33
`-W stagein=<list>`	"Input/Output File Staging" on page 33
`-W stageout=<list>`	"Input/Output File Staging" on page 33
`-W umask=<value>`	"Changing Linux Job umask" on page 47
`-X`	"Receiving X Output from Interactive Linux Jobs" on page 126
`-z`	"Suppressing Printing Job Identifier to stdout" on page 31
`--version`	Displays PBS version information.

2.5.1 Specifying Email Notification

For each job, PBS can send mail to designated recipients when that job or subjob reaches specific points in its lifecycle. There are points in the life of the job where PBS always sends email, and there are points where you can choose to receive email; see the table below for a list.

Table 2-2: Points in Job/Reservation Lifecycle when PBS Sends Mail

Point in Lifecycle	Always Sent or Optional?
Job cannot be routed, either because the job makes too many routing hops or because all destinations reject it	Optional. Mail is sent when `-m a` is specified. For subjobs, mail is sent when `-m aj` is specified.
Job is deleted by job owner	Optional; depends on `qdel -Wsuppress_email`
Job is deleted by someone other than job owner	Always
Job or subjob is aborted by PBS: Job or subjob cannot be executed because of bad user/group account, bad checkpoint/restart file, system error, bad resource request, or bad dependency	Optional. Mail is sent when `-m a` is specified. For subjobs, mail is sent when `-m aj` is specified.

Table 2-2: Points in Job/Reservation Lifecycle when PBS Sends Mail

Point in Lifecycle	Always Sent or Optional?
Job is held by PBS with bad password hold	Always
Job begins execution	Optional
Job ends execution	Optional
Stagein fails	Always
All file stageout attempts fail	Always
Reservation is confirmed or denied	Always

PBS always sends you mail when your job or subjob is deleted. For job arrays, PBS sends one email per subjob.

You can restrict the number of job-related emails PBS sends when you delete jobs or subjobs; see section 2.5.1.3, "Restricting Number of Job Deletion Emails", on page 27.

2.5.1.1 Specifying Job Lifecycle Email Points

The set of points where PBS sends mail is specified in the Mail_Points job attribute. When you use the `-j` suboption with one or more of the other sub-options, PBS sends mail for each subjob; without this suboption, PBS sends mail only for jobs and parent array jobs. You can set the Mail_Points attribute using the following methods:

- The `-m <mail points>` option to `qsub`
- The `-m <mail points>` option to `qalter`
- The `#PBS -WMail_Points=<mail points>` PBS directive

The *mail points* argument is a string which consists of either:

- The single character "*n*"
- One or more of the characters "*a*", "*b*", and "*e*" with optional "*j*".

The following table lists the sub-options to the `-m` option:

Table 2-3: Sub-options to m Option

Suboption	Meaning
n	Do not send mail
a	Send mail when job or subjob is aborted by batch system. This is the default
b	Send mail when job or subjob begins execution Example: `Begun execution`
e	Send mail when job or subjob ends execution
j	Send mail for subjobs. Must be combined with one or more of a, b, or e sub-options.

Example 2-8: PBS sends mail when the job is aborted or ends:

```
qsub -m ae my_job
#PBS -m ae
```

2.5.1.2 Setting Email Recipient List

The list of recipients to whom PBS sends mail is specified in the Mail_Users job attribute. You can set the Mail_Users attribute using the following methods:

- The `-M <mail recipients>` option to `qsub`
- The `#PBS -WMail_Users=<mail recipients>` PBS directive

The mail recipients argument is a list of usernames with optional hostnames in this format:

<username>[@<hostname>][,<username>[@<hostname>],...]

For example:

```
qsub -M user1@mydomain.com my_job
```

When you set this option for a job array, PBS sets the option for each subjob, and sends mail for each subjob.

2.5.1.3 Restricting Number of Job Deletion Emails

By default, when you delete a job or subjob, PBS sends you email. You can use `qdel -Wsuppress_email=<limit>` to restrict the number of emails sent to you each time you use `qdel`. This option behaves as follows:

limit >=*1*

You receive at most *limit* emails.

limit = *0*

PBS ignores this option.

limit =*-1*

You receive no emails.

2.5.2 Specifying Job Name

If you submit a job using a script without specifying a name for the job, the name of the job defaults to the name of the script. If you submit a job without using a script and without specifying a name for the job, the job name is STDIN.

You can specify the name of a job using the following methods:

- Using `qsub -N <job name>`
- Using `#PBS -N <job name>`
- Using `#PBS -WJob_Name=<job name>`

For example:

```
qsub -N myName my_job
#PBS -N myName
#PBS -WJob_Name=my_job
```

The job name can be up to 236 characters in length, and must consist of printable, non-whitespace characters. The first character must be alphabetic, numeric, hyphen, underscore, or plus sign.

2.5.3 Specifying a Project for a Job

In PBS, a project is a way to organize jobs independently of users and groups. You can use a project as a tag to group a set of jobs. Each job can be a member of up to one project.

Projects are not tied to users or groups. One user or group may run jobs in more than one project. For example, user Bob runs JobA in ProjectA and JobB in ProjectB. User Bill runs JobC in ProjectA. User Tom runs JobD in ProjectB. Bob and Tom are in Group1, and Bill is in Group2.

A job's project attribute specifies the job's project. See "project" on page 341 of the PBS Professional Reference Guide. You can set the job's project attribute in the following ways:

- At submission using `qsub -P <project name>`
- After submission, via `qalter -P <project name>`; see "qalter" on page 130 of the PBS Professional Reference Guide

2.5.4 Specifying Job Username

By default PBS runs your job under the username with which you log in. You may need to run your job under a different username depending on which PBS server runs the job. You can specify a list of usernames under which the job can run. All but one of the entries in the list must specify the PBS server hostname as well, so that PBS can choose which username to use by looking at the hostname. You can include one entry in the list that does not specify a hostname; PBS uses this in the case where the job was sent to a server that is not in your list.

The list of usernames is stored in the User_List job attribute. The value of this attribute defaults to the username under which you logged in. There is no limit to the length of the attribute.

List entries are in the following format:

<username>@<hostname>[,<username>@<hostname> ...][,<username>]

You can set the value of User_List at submission time by using `qsub -u <username>` or later via `qalter -u <username>` .

Example 2-9: Our user is UserS on the submission host HostS, UserA on server ServerA, and UserB on server ServerB, and is UserC everywhere else. Note that this user must be UserA on all ExecutionA and UserB on all ExecutionB machines. Then our user can use "`qsub -u UserA@ServerA,UserB@ServerB,UserC`" for the job. The job owner will always be UserS. On Linux, UserA, UserB, and UserC must each have `.rhosts` files at their servers that list UserS.

2.5.4.1 Caveats for Changing Job Username

- Wherever your job runs, you must have permission to run the job under the specified username:
  - For Linux, see section 1.4.2.7, "User Authorization Under Linux", on page 6.
  - For Windows, see section 1.4.3.4, "User Authorization under Windows", on page 7.
- Usernames are limited to 256 characters.

2.5.5 Specifying Job Group ID

Your username can belong to more than one group, but each PBS job is only associated with one of those groups. By default, the job runs under the primary group. The job's group is specified in the group_list job attribute. You can change the group under which your job runs on the execution host either on the command line or by using a PBS directive:

```
qsub -W group_list=<group list>
#PBS group_list=<group list>
```

For example:

```
qsub -W group_list=grpA,grpB@jupiter my_job
```

The <*group list*> argument has the following form:

<group>[@<hostname>][,<group>[@<hostname>],...]

You can specify only one group name per host.

You can specify only one group without a corresponding host; that group name is used for execution on any host not named in the argument list.

The *group_list* defaults to the primary group of the username under which the job runs.

2.5.5.1 Group Names Under Windows

Under Windows, the primary group is the first group found for the username by PBS when querying the accounts database.

Under Windows, the default group assigned is determined by what the Windows API NetUserGetLocalGroup() and NetUserGetGroup() return as first entry. PBS checks the former output (the local groups) and returns the first group it finds. If the former call does not return any value, then it proceeds to the latter call (the Global groups). If PBS does not find any output on the latter call, it uses the default "Everyone".

We do not recommend depending on always getting "Users" in this case. Sometimes you may submit a job without the `–Wgroup_list` option, and get a default group of "None" assigned to your job.

2.5.6 Specifying Accounting String

You can associate an accounting string with your job by setting the value of the Account_Name job attribute. This attribute has no default value. You can set the value of Account_Name at the command line or in a PBS directive:

```
qsub -A <accounting string>
#PBS Account_Name=<accounting string>
```

The <*accounting string*> can be any string of characters; PBS does not attempt to interpret it.

2.5.7 Specifying Server and/or Queue

By default, PBS provides a default server and a default queue, so that jobs submitted without a server or queue specification end up in the default queue at the default server.

If your administrator has configured the PBS server with more than one queue, and has configured those queues to accept jobs from you, you can submit your job to a non-default queue.

- If you will submit jobs mainly to one non-default server, set the PBS_SERVER environment variable to the name of your preferred server. Once this environment variable is set to your preferred server, you don't need to specify that server when you submit a job to it.
- If you will submit jobs mostly to the default server, and just want to submit this one to a specific queue at a non-default server:
  - Use `qsub -q <queue name>@<server name>`
  - Use `#PBS -q <queue name>@<server name>`
- If you will submit jobs mostly to the default server, and just want to submit this one to the default queue at a non-default server:
  - Use `qsub -q @<server name>`
  - Use `#PBS -q @<server name>`
- You can submit your job to a non-default queue at the default server, or the server given in the PBS_SERVER environment variable if it is defined:
  - Use `qsub -q <queue name>`
  - Use `#PBS -q <queue name>`

If the PBS server has no default queue and you submit a job without specifying a queue, the `qsub` command will complain.

PBS or your administrator may move your job from one queue to another. You can see which queue has your job using `qstat [job ID]`. The job's queue attribute contains the name of the queue where the job resides.

Examples:

```
qsub -q queue my_job
qsub -q @server my_job
#PBS -q queue1
qsub -q queue1@myserver my_job
qsub -q queue1@myserver.mydomain.com my_job
```

2.5.7.1 Using or Avoiding Dedicated Time

Dedicated time is one or more specific time periods defined by the administrator. These are not repeating time periods. Each one is individually defined.

During dedicated time, the only jobs PBS starts are those in special dedicated time queues. PBS schedules non-dedicated jobs so that they will not run over into dedicated time. Jobs in dedicated time queues are also scheduled so that they will not run over into non-dedicated time. PBS will attempt to backfill around the dedicated-non-dedicated time borders.

PBS uses walltime to schedule within and around dedicated time. If a job is submitted without a walltime to a non-dedicated-time queue, it will not be started until all dedicated time periods are over. If a job is submitted to a dedicated-time queue without a walltime, it will never run.

To submit a job to be run during dedicated time, use the *`-q <queue name>`* option to *`qsub`* and give the name of the dedicated-time queue you wish to use as the queue name. Queues are created by the administrator; see your administrator for queue name(s).

2.5.8 Suppressing Printing Job Identifier to stdout

To suppress printing the job identifier to standard output, use the `-z` option to `qsub`. You can use it at the command line or in a PBS directive:

```
qsub -z my_job
#PBS -z
```

There is no associated job attribute for this option.

2.5.9 Running qsub in the Foreground

Normally, `qsub` runs in the background. You can run it in the foreground by using the `-f` option. By default, `qsub` attempts to communicate with a background `qsub` daemon that may have been instantiated from an earlier invocation. This background daemon can be holding onto an authenticated server connection, speeding up performance.

This option can be helpful when you are submitting a very short job which submits another job, or when you are running codes written in-house for Windows.

2.6 PBS Jobs on Cray HPE Cray System Management

Submitting a PBS job on an HPE Cray System Management system is exactly like submitting a job on a standard Linux machine.

2.7 Job Submission Caveats

2.7.1 Caveats for Mixed Linux-Windows Operation

- You cannot submit a Linux job from a Windows client
- In order to submit a Windows job, specify that the architecture is Windows. For example:

```
export PBS_AUTH_METHOD=pwd; qsub -lselect=1:arch=windows -- pbs-sleep 100
```

3 Job Input & Output Files

3.1 Introduction to Job File I/O in PBS

PBS allows you to manage input files, output files, standard output, and standard error. PBS has two mechanisms for handling job files; you use staging for input and output files, and you select whether *stdout* and/or *stderr* are copied back using the Keep_Files job attribute.

3.2 Input/Output File Staging

File staging is a way to specify which input files should be copied onto the execution host before the job starts, and which output files should be copied off the execution host when it finishes.

3.2.1 Staging and Execution Directory: User Home vs. Job-specific

A job's *staging and execution directory* is the directory to which input files are staged, and from which output files are staged. It is also the current working directory for the job script, for tasks started via the `pbs_tm()` API, and for the epilogue. This directory is either your home directory or a job-specific directory created by PBS just for this job.

PBS can create temporary directories specific to each job to be used as job staging and execution directories. If each job has its own directories, you avoid filename collisions. PBS creates these either under your home directory or under some other location depending on how the execution host is configured.

If you use job-specific staging and execution directories, you don't need to have a home directory on each execution host, as long as those hosts are configured properly.

This table lists the differences between using your home directory for staging and execution and using a job-specific staging and execution directory created by PBS.

Table 3-1: Differences Between User Home and Job-specific Directory for Staging and Execution

Question Regarding Action, Requirement, or Setting	User Home Directory	Job-specific Directory
Does PBS have to create a job-specific staging and execution directory?	No	Yes if not in home directory
User's home directory must exist on execution host(s)?	Yes	No
Standard out and standard error automatically deleted when `qsub -k` option is used?	No	Yes

Table 3-1: Differences Between User Home and Job-specific Directory for Staging and Execution

Question Regarding Action, Requirement, or Setting	User Home Directory	Job-specific Directory
When are staged-out files are deleted?	Successfully staged-out files are deleted; others go to "undelivered"	Only after all are successfully staged out
Staging and execution directory deleted after job finishes?	No	Yes
What is job's sandbox attribute set to?	*HOME* or not set	*PRIVATE*

3.2.2 Using Job-specific Staging and Execution Directories

3.2.2.1 Setting the Job Staging and Execution Directory

Whether or not PBS creates job-specific staging and execution directories for a job is controlled by the job's sandbox attribute:

- If the job's sandbox attribute is set to *PRIVATE*, PBS creates a staging and execution directory for each job.
- If the job's sandbox attribute is set to *HOME* or is unset, PBS does not create job-specific staging and execution directories. Instead PBS uses your home directory.

You can set the sandbox attribute via `qsub`, or through a PBS directive. For example:

```
qsub -Wsandbox=PRIVATE
```

The job's sandbox attribute cannot be altered while the job is executing.

3.2.2.2 Where to Find the Staging and Execution Directory

PBS sets the job's jobdir attribute to the pathname of the job's staging and execution directory on the primary host. You can view this attribute by using `qstat -f`, only while the job is executing. The value of jobdir is not retained if a job is rerun; it is undefined whether jobdir is visible or not when the job is not executing. This is a read-only attribute.

PBS sets the environment variable PBS_JOBDIR to the pathname of the staging and execution directory on the primary execution host. PBS_JOBDIR is added to the job script process, any job tasks, and the prologue and epilogue.

3.2.3 Attributes and Environment Variables Affecting Staging

The following attributes and environment variables affect staging and execution.

Table 3-2: Attributes and Environment Variables Affecting Staging

Job's Attribute or Environment Variable	Effect
sandbox attribute	Determines whether PBS uses user's home directory or creates job-specific directory for staging and execution. When set to *PRIVATE*, PBS creates job-specific directories. If value is *HOME* or is unset, PBS uses the user's home directory for staging and execution. User-settable per job via `qsub -W` or through a PBS directive.
stagein attribute	Sets list of files or directories to be staged in. User-settable per job via `qsub -W`. Format: *execution_path@storage_host:storage_path* The *execution_path* is the path to the staging and execution directory. On stagein, *storage_path* is the path where the input files normally reside.
stageout attribute	Sets list of files or directories to be staged out. User-settable per job via `qsub -W`. Format: *execution_path@storage_host:storage_path* The *execution_path* is the path to the staging and execution directory. On stageout, *storage_path* is the path where output files will end up.
Keep_Files attribute	Determines whether output and/or error files remain on execution host. User-settable per job via `qsub -k` or through a PBS directive. If the Keep_Files attribute is set to *o* and/or *e* (output and/or error files remain in the staging and execution directory) and the job's sandbox attribute is set to *PRIVATE*, standard out and/or error files are removed when the staging and execution directory is removed at job end along with its contents. If direct write for files is specified via the `-d` suboption to the `-k` argument, files are not removed. See section 3.3.5, "Keeping Output and Error Files on Execution Host", on page 46.
jobdir attribute	Set to pathname of staging and execution directory on primary execution host. Read-only; viewable via `qstat -f`.
Remove_Files attribute	Specifies whether standard output and/or standard error files are automatically removed (deleted) upon job completion.
PBS_JOBDIR environment variable	Set to pathname of staging and execution directory on primary execution host. Added to environments of job script process, `pbs_tm` job tasks, and prologue and epilogue.
TMPDIR environment variable	Location of job-specific scratch directory.

3.2.4 Specifying Files To Be Staged In or Staged Out

You can specify files to be staged in before the job runs and staged out after the job runs by setting the job's stagein and stageout attributes. You can use options to qsub, or directives in the job script:

qsub -Wstagein=<execution path>@<input file storage host>:<input file storage path>[,...] -Wstageout=<execution path>@<output file storage host>:<output file storage path>[,...]

#PBS -W stagein=<execution path>@<input file storage host>:<input file storage path>[,...]

#PBS -W stageout=<execution path>@<output file storage host>:<output file storage path>[,...]

The name *execution path* is the name of the file in the job's staging and execution directory (on the execution host). The *execution path* can be relative to the job's staging and execution directory, or it can be an absolute path.

The '@' character separates the execution specification from the storage specification.

The name *storage path* is the file name on the host specified by *storage host*. For stagein, this is the location where the input files come from. For stageout, this is where the output files end up when the job is done. You must specify a hostname. The path can be absolute, or it can be relative to your home directory on the machine named *storage host*.

For stagein, the direction of travel is **from** *storage path* **to** *execution path*.

For stageout, the direction of travel is **from** *execution path* **to** *storage path*.

The following example shows how to use a directive to stagein a file named `grid.dat` located in the directory `/u/user1` on the host called serverA. The staged-in file is copied to the staging and execution directory and given the name `data1`. Since *execution path* is evaluated relative to the staging and execution directory, it is not necessary to specify a full pathname for `data1`.

```
#PBS -W stagein=data1@serverA:/u/user1/grid.dat ...
```

To use the `qsub` option to stage in the file residing on myhost, in `/Users/myhome/mydata/data1`, calling it `input_data1` in the staging and execution directory:

```
qsub -W stagein=input_data1@myhost:/Users/myhome/mydata/data1
```

To stage more than one file or directory, use a comma-separated list of paths, and enclose the list in double quotes. For example, to stage two files `data1` and `data2` in:

```
qsub -W stagein="input1@hostA:/myhome/data1,input2@hostA:/myhome/data1"
```

3.2.5 Caveats and Requirements for Staging

3.2.5.1 Linux: Staging and Special Characters

If you need to use special characters, such as parentheses, in your file or directory names, enclose that part of the path in an extra layer of quotes. Syntax:

-W stageout="<execution path> @<storage host>:'<storage path>'"

Example:

```
-W stageout="myoutfile@myhost:'/home/user1/outfile(1234)'"
```

3.2.5.2 Windows: Staging and Special Characters or Paths

3.2.5.2.i Special Characters

Under Windows, if your path contains special characters such as spaces, backslashes (\), colons (:), or drive letter specifications, enclose the staging specification in double quotes. For example, to stage the grid.dat file on drive D at hostB to the execution file named "dat1" on drive C:

```
qsub -W stagein="dat1@hostB:D\Documents and Settings\grid.dat"
```

3.2.5.2.ii Using UNC Paths

If you use a UNC path to stage in or out, the hostname is optional. If you use a non-UNC path, the hostname is required.

3.2.5.3 Path Names for Staging

- It is advisable to use an absolute pathname for the *storage path*. Remember that the path to your home directory may be different on each machine, and that when using sandbox = *PRIVATE*, you may or may not need to have a home directory on all execution machines.
- Always use a relative pathname for *execution path* when the job's staging and execution directory is created by PBS, meaning when using a job-specific staging and execution directory, do not use an absolute path in *execution path*.

3.2.5.4 Required Permissions

You must have read permission for any files or directories that you will stage in, and write permission for any files or directories that you will stage out.

3.2.5.5 Warning About Ampersand

You cannot use the ampersand ("&") in any staging path. Staging will fail.

3.2.5.6 Interactive Jobs and File I/O

When an interactive job finishes, staged files may not have been copied back yet.

3.2.5.7 Copying Directories Into and Out Of the Staging and Execution Directory

You can stage directories into and out of the staging and execution directory the same way you stage files. The *storage path* and *execution path* for both stagein and stageout can be a directory. If you stagein or stageout a directory, PBS copies that directory along with all of its files and subdirectories. At the end of the job, the directory, including all files and subdirectories, is deleted. This can create a problem if multiple jobs are using the same directory, but you can avoid this by having PBS create job-specific staging and execution directories; to do so, set sandbox=*PRIVATE* for your jobs.

3.2.5.8 Wildcards In File Staging

You can use wildcards when staging files and directories, according to the following rules.

- The asterisk "*" matches one or more characters.
- The question mark "?" matches a single character.
- All other characters match only themselves.
- Wildcards inside of quote marks are expanded.
- Wildcards cannot be used to match Linux files that begin with period "." or Windows files that have the "SYSTEM" or "HIDDEN" attributes.
- When using the `qsub` command line on Linux, you must prevent the shell from expanding wildcards. For some shells, you can enclose the pathnames in double quotes. For some shells, you can use a backslash before the wildcard.
- Wildcards can only be used in the source side of a staging specification. This means they can be used in the *storage path* specification for stagein, and in the *execution path* specification for stageout.
- When staging using wildcards, the destination must be a directory. If the destination is not a directory, the result is undefined. So for example, when staging out all `.out` files, you must specify a directory for *storage path*.
- Wildcards can only be used in the final path component, i.e. the basename.
- When wildcards are used during stagein, PBS will not automatically delete staged files at job end if PBS did not create a job-specific staging and execution directory. If PBS created the staging and execution directory, that directory and all its contents are deleted at job end.

3.2.6 Examples of File Staging

Example 3-1: Stage out all files from the execution directory to a specific directory:

Linux

```
-W stageout=*@myworkstation:/user/project1/case1
```

Windows

```
-W stageout=*@mypc:E:\project1\case1
```

Example 3-2: Stage out specific types of result files and disregard the scratch and other temporary files after the job terminates. The result files that are interesting for this example end in '.dat':

Linux

```
-W stageout=*.dat@myworkstation:project3/data
```

Windows

```
-W stageout=*.dat@mypc:C:\project\data
```

Example 3-3: Stage in all files from an application data directory to a subdirectory:

Linux

```
-W stagein=jobarea@myworkstation:crashtest1/*
```

Windows

```
-W stagein=jobarea@mypc:E:\crashtest1\*
```

Example 3-4: Stage in data from files and directories matching "wing*":

Linux

```
-W stagein=.@myworkstation:848/wing*
```

Windows

```
-W stagein=.@mypc:E:\flowcalc\wing*
```

Example 3-5: Stage in .bat and .dat files to job area:

Linux:

```
-W stagein=jobarea@myworkstation:/users/me/crash1.?at
```

Windows:

```
-W stagein=jobarea@myworkstation:C:\me\crash1.?at
```

3.2.6.1 Example of Using Job-specific Staging and Execution Directories

In this example, you want the file "jay.fem" to be delivered to the job-specific staging and execution directory given in PBS_JOBDIR, by being copied from the host "submithost". The job script is executed in PBS_JOBDIR and "jay.out" is staged out from PBS_JOBDIR to your home directory on the submission host (i.e., "storage host"):

```
qsub -Wsandbox=PRIVATE -Wstagein=jay.fem@submithost:jay.fem -Wstageout=jay.out@submithost:jay.out
```

3.2.7 Summary of the Job Lifecycle

This is a summary of the steps performed by PBS. The steps are not necessarily performed in this order.

- On each execution host, if specified, PBS creates a job-specific staging and execution directory.
- PBS sets PBS_JOBDIR and the job's jobdir attribute to the path of the job's staging and execution directory.
- On each execution host allocated to the job, PBS creates a temporary scratch directory.
- PBS sets the TMPDIR environment variable to the pathname of the temporary scratch directory.
- If any errors occur during directory creation or the setting of variables, the job is requeued.
- PBS stages in any files or directories.
- The prologue is run on the primary execution host, with its current working directory set to PBS_HOME/mom_priv, and with PBS_JOBDIR and TMPDIR set in its environment.
- The job is run as you on the primary execution host.
- The job's associated tasks are run as you on the execution host(s).
- The epilogue is run on the primary execution host, with its current working directory set to the path of the job's staging and execution directory, and with PBS_JOBDIR and TMPDIR set in its environment.
- PBS stages out any files or directories.
- PBS removes standard error and/or standard output according to the value of the job's Remove_Files attribute.
- PBS removes any staged files or directories.
- If PBS created them, PBS removes any job-specific staging and execution directories and their contents, and all TMPDIRs and their contents.
- PBS writes the final job accounting record and purges any job information from the server's database.

3.2.8 Detailed Description of Job Lifecycle

3.2.8.1 Creation of TMPDIR

For each host allocated to the job, PBS creates a job-specific temporary scratch directory for the job. If the temporary scratch directory cannot be created, the job is aborted.

3.2.8.2 Choice of Staging and Execution Directories

If the job's sandbox attribute is set to *PRIVATE*, PBS creates job-specific staging and execution directories for the job. If the job's sandbox attribute is set to *HOME*, or is unset, PBS uses your home directory for staging and execution.

3.2.8.2.i Job-specific Staging and Execution Directories

If the staging and execution directory cannot be created the job is aborted. If PBS fails to create a staging and execution directory, see the system administrator.

You should not depend on any particular naming scheme for the new directories that PBS creates for staging and execution.

3.2.8.2.ii User Home Directory as Staging and Execution Directory

You must have a home directory on each execution host. The absence of your home directory is an error and causes the job to be aborted.

3.2.8.3 Setting Environment Variables and Attributes

PBS sets PBS_JOBDIR and the job's jobdir attribute to the pathname of the staging and execution directory on the primary execution host. The TMPDIR environment variable is set to the pathname of the job-specific temporary scratch directory.

3.2.8.4 Staging Files Into Staging and Execution Directories

PBS stages files in to the primary execution host. PBS evaluates `execution path` and `storage path` relative to the staging and execution directory given in PBS_JOBDIR, whether this directory is your home directory or a job-specific directory created by PBS. PBS copies the specified files and/or directories to the job's staging and execution directory.

3.2.8.5 Running the Prologue

The MoM's prologue is run on the primary host as root, with the current working directory set to `PBS_HOME/mom_priv`, and with PBS_JOBDIR and TMPDIR set in its environment.

3.2.8.6 Job Execution

PBS runs the job script on the primary host as you. PBS also runs any tasks created by the job as you. The job script and tasks are executed with their current working directory set to the job's staging and execution directory, and with PBS_JOBDIR and TMPDIR set in their environment.

3.2.8.7 Standard Out and Standard Error

The job's `stdout` and `stderr` files are created directly in the job's staging and execution directory on the primary execution host, unless you specify that files should be written directly to their final destination via the `-d` sub-option to the `-k` option.

3.2.8.7.i Job-specific Staging and Execution Directories

If you set sandbox to *PRIVATE*, and you specified the `qsub -k` option, the `stdout` and `stderr` files are **not** automatically copied out of the staging and execution directory at job end; they will be deleted when the directory is automatically removed. Note that if you specified that files should be written directly to their final destination via the `-d` sub-option to the `-k` option, they are not created in the staging and execution directory in the first place.

3.2.8.7.ii User Home Directory as Staging and Execution Directory

If you set sandbox to *HOME* or left it unset, and you specified the -k option to qsub, standard out and/or standard error files are retained on the primary execution host instead of being returned to the submission host, and are not deleted after job end.

3.2.8.8 Running the Epilogue

PBS runs the epilogue on the primary host as root. The epilogue is executed with its current working directory set to the job's staging and execution directory, and with PBS_JOBDIR and TMPDIR set in its environment.

3.2.8.9 Staging Files Out and Removing Execution Directory

When PBS stages files out, it evaluates execution path and storage path relative to PBS_JOBDIR. Files that cannot be staged out are saved in PBS_HOME/undelivered.

3.2.8.9.i Job-specific Staging and Execution Directories

If PBS created job-specific staging and execution directories for the job, it cleans them up at the end of the job; it removes the staging and execution directory and all of its contents, on all execution hosts.

3.2.8.10 Removing TMPDIRs and Files

PBS removes all TMPDIRs, along with their contents. If Remove_Files specifies output and/or error files, these files are removed.

3.2.9 Staging with Job Arrays

File staging is supported for job arrays. See "File Staging for Job Arrays" on page 157.

3.2.10 Stagein and Stageout Failure

3.2.10.1 File Stagein Failure

When stagein fails, the job is placed in a 30-minute wait to allow you time to fix the problem. Typically this is a missing file or a network outage. Email is sent to the job owner when the problem is detected. Once the problem has been resolved, the job owner or a PBS Operator may remove the wait by resetting the time after which the job is eligible to be run via the -a option to qalter. The server will update the job's comment with information about why the job was put in the wait state. When the job is eligible to run, it may run on different vnodes.

3.2.10.2 File Stageout Failure

When stageout encounters an error, there are three retries. PBS waits 1 second and tries again, then waits 11 seconds and tries a third time, then finally waits another 21 seconds and tries a fourth time. Email is sent to the job owner if all attempts fail. Files that cannot be staged out are saved in PBS_HOME/undelivered. See section 3.3.8.1, "Non-delivery of Output", on page 48.

3.3 Managing Output and Error Files

3.3.1 Default Behavior For Output and Error Files

By default, PBS copies the standard output (`stdout`) and standard error (`stderr`) files back to $PBS_O_WORKDIR on the submission host when a job finishes. When `qsub` is run, it sets $PBS_O_WORKDIR to the current working directory where the `qsub` command is executed. This means that if you want your job's `stdout` and `stderr` files to be delivered to your submission directory, you do not need to do anything.

The following options to the `qsub` command control where `stdout` and `stderr` are created and whether and where they are copied when the job is finished:

sandbox

By default, PBS runs the job script in the owner's home directory. If sandbox is set to *PRIVATE*, PBS creates a job-specific staging and execution directory, and runs the job script there. See section 3.2.2.1, "Setting the Job Staging and Execution Directory", on page 34.

k

k {e | o | eo | oe | n}

When used with the `-e`, `-o`, `-eo`, `-oe`, and `-n` suboptions, specifies whether and which of `stdout` and `stderr` is retained in the job's execution directory. When set, this option overrides `-o <output path>` and `-e <error path>`. See section 3.3.5, "Keeping Output and Error Files on Execution Host", on page 46.

kd {e | o | eo | oe}

When used with the `-d` suboption, specifies that output and/or error files are written directly to the final destination. Requires `e` and/or `o` suboptions. See section 3.3.6, "Writing Files Directly to Final Destination", on page 47.

o

Specifies destination for `stdout`. Overridden by `k` when `k` is set. See section 3.3.2, "Paths for Output and Error Files", on page 44.

e

Specifies destination for `stderr`. Overridden by `k` when `k` is set. See section 3.3.2, "Paths for Output and Error Files", on page 44.

R

Specifies whether standard output and/or standard error are deleted upon job completion. See section 3.3.3, "Avoiding Creation of stdout and/or stderr", on page 45.

The following table shows how these options control creation and copying of `stdout` and `stderr`:

Table 3-3: How `k`, sandbox, `o`, and `e` Options to `qsub` Affect `stdout` and `stderr`

sandbox	`-k` (o, e, eo, oe)	-e, -o	-R	-k d	Where `stdout`, `stderr` Are Created	Where `stdout`, `stderr` Are Copied
HOME or unset	unset	unset	unset	unset	`PBS_HOME/spool`	PBS_O_WORKDIR, which is job submission directory
HOME or unset	unset	*<path>*	unset	unset	`PBS_HOME/spool`	Destination specified in `-o <path>` and/or `-e <path>`
HOME or unset	*e, o, eo, oe*	unset	unset	unset	Job submitter's home directory on execution host	Not copied; left in submitter's home directory on execution host, and not deleted
HOME or unset	*e, o, eo, oe*	*<path>*	unset	unset	Job submitter's home directory on execution host	Not copied; left in submitter's home directory on execution host, and not deleted
PRIVATE	unset	unset	unset	unset	Job-specific execution directory created by PBS	PBS_O_WORKDIR, which is job submission directory
PRIVATE	unset	*<path>*	unset	unset	Job-specific execution directory created by PBS	Destination specified in `-o <path>` and/or `-e <path>`
PRIVATE	*e, o, eo, oe*	unset	unset	unset	Job-specific execution directory created by PBS	Not copied; left in job-specific execution directory; deleted when job-specific execution directory is deleted
PRIVATE	*e, o, eo, oe*	*<path>*	unset	unset	Job-specific execution directory created by PBS	Not copied; left in job-specific execution directory; deleted when job-specific execution directory is deleted
any	any	any	*-R e/o*	any	Deleted regardless of where created	Does not exist, so not copied
any	any	any	unset	*-k d <o and/or e>*	Final destination specified in `-o <output path>` and/or `-e <error path>`, if MoM can reach it	Does not exist, so not copied

- You can specify a path for `stdout` and/or `stderr`: see section 3.3.2, “Paths for Output and Error Files”, on page 44.
- You can merge `stdout` and `stderr`: see section 3.3.4, “Merging Output and Error Files”, on page 45.
- You can prevent creation of `stdout` and/or `stderr`: see section 3.3.3, “Avoiding Creation of stdout and/or stderr”, on page 45.
- You can choose whether to retain `stdout` and/or `stderr` on the execution host: see section 3.3.5, “Keeping Output and Error Files on Execution Host”, on page 46.
- You can specify that output and/or error files are written directly to the final destination. See section 3.3.6, “Writing Files Directly to Final Destination”, on page 47.
- You can specify that output and/or error files are deleted when the job finishes. See section 3.3.3, “Avoiding Creation of stdout and/or stderr”, on page 45.

3.3.2 Paths for Output and Error Files

3.3.2.1 Default Paths for Output and Error Files

By default, PBS names the output and error files for your job using the job name and the job's sequence number. The output file name is specified in the Output_Path job attribute, and the error file name is specified in the Error_Path job attribute.

The default output filename has this format:

<job name>.o<sequence number>

The default error filename has this format:

<job name>.e<sequence number>

The *job name*, if not specified, defaults to the script name. For example, if the job ID is `1234.exampleserver` and the script name is "`myscript`", the error file is named `myscript.e1234`. If you specify a name for your job, the script name is replaced with the job name. For example, if you name your job "fixgamma", the output file is named `fixgamma.o1234`.

For details on naming your job, see section 2.5.2, “Specifying Job Name”, on page 27.

3.3.2.2 Specifying Paths

You can specify the path and name for the output and error files for each job, by setting the value for the Output_Path and Error_Path job attributes. You can set these attributes using the following methods:

- Use the `-o <output path>` and `-e <error path>` options to `qsub`
- Use `#PBS Output_Path=<path>` and `#PBS Error_Path=<path>` directives in the job script

The `path` argument has the following form:

[<hostname>:]<pathname>

where *hostname* is the name of a host and *pathname* is the path name on that host.

You can specify relative or absolute paths. If you specify only a file name, it is assumed to be relative to your home directory. Do not use variables in the path.

The following examples show how you can specify paths:

```
#PBS -o /u/user1/myOutputFile
#PBS -e /u/user1/myErrorFile

qsub -o myOutputFile my_job
qsub -o /u/user1/myOutputFile my_job
qsub -o myWorkstation:/u/user1/myOutputFile my_job
qsub -e myErrorFile my_job
qsub -e /u/user1/myErrorFile my_job
qsub -e myWorkstation:/u/user1/myErrorFile my_job
```

3.3.2.3 Specifying Paths from Windows Hosts

3.3.2.3.i Using Special Characters in Paths

If you submit your job from a Windows host, you may end up using special characters such as spaces, backslashes ("\"), and colons (":") for specifying pathnames, and you may need drive letter specifications. The following examples are allowed:

```
qsub -o \temp\my_out job.scr
qsub -e "myhost:e:\Documents and Settings\user\Desktop\output"
```

The error output of the example job is to be copied onto the `e:` drive on `myhost` using the path "`\Documents and Settings\user\Desktop\output`".

3.3.2.3.ii Using UNC Paths

If you use a UNC path for output or error files, the hostname is optional. If you use a non-UNC path, the hostname is required.

3.3.2.4 Caveats for Paths

Enclose arguments to `qsub` in quotes if the arguments contain spaces.

3.3.3 Avoiding Creation of `stdout` and/or `stderr`

For each job, PBS always creates the job's output and error files. The location where files are created is listed in Table 3-3, “How k, sandbox, o, and e Options to qsub Affect stdout and stderr,” on page 43.

If you do not want `stdout` and/or `stderr`, you can do either of the following:

- Specify that PBS deletes the file(s) when the job finishes, using the `-R` option to `qsub` or `qalter`. The `-R` option takes *o*, *e*, *eo*, or *oe* as sub-options. For example, to have PBS delete the error file:
  ```
  qsub -R e job.sh
  ```
- Redirect them to `/dev/null` within the job script. For example, to redirect `stdout` and `stderr` to `/dev/null`:
  ```
  exec >&/dev/null 1>&2
  ```
- Standard output and standard error are normally written to a location such as `/var/spool`, then copied to their final location. To avoid creating these files at all, and to avoid copying them, use direct write to send them to `/dev/null`:
  ```
  qsub -koed -o /dev/null -e /dev/null
  ```
  Your administrator must also set up the MoM's configuration file to support this.

3.3.4 Merging Output and Error Files

By default, PBS creates separate standard output and standard error files for each job. You can specify that `stdout` and `stderr` are to be joined by setting the job's Join_Path attribute. The default for the attribute is *n*, meaning that no joining takes place. You can set the attribute using the following methods:

- Use `qsub -j <joining option>`
- Use `#PBS Join_Path=<joining option>`

You can specify one of the following *joining options*:

oe

Standard output and standard error are merged, intermixed, into a single stream, which becomes standard output.

eo
: Standard output and standard error are merged, intermixed, into a single stream, which becomes standard error.

n
: Standard output and standard error are not merged.

For example, to merge standard output and standard error for my_job into standard output:

```
qsub -j oe my_job
#PBS -j oe
```

3.3.5 Keeping Output and Error Files on Execution Host

By default, PBS copies `stdout` and `stderr` to the job's submission directory. You can specify that PBS keeps `stdout`, `stderr`, or both in the job's execution directory on the execution host. This behavior is controlled by the job's Keep_Files attribute. You can set this attribute to one of the following values:

e
: PBS keeps `stderr` in the job's staging and execution directory on the primary execution host.

o
: PBS keeps `stdout` in the job's staging and execution directory on the primary execution host.

eo, oe
: PBS keeps both standard output and standard error on the primary execution host, in the job's staging and execution directory.

n
: PBS does not keep either file on the execution host.

d
: PBS writes both `stdout` and `stderr` to their final destinations. Requires `-o <output path>` and/or `-e <error path>` options. See section 3.3.6, “Writing Files Directly to Final Destination”, on page 47.

The default value for Keep_Files is "*n*".

You can set the value of the Keep_Files job attribute using the following methods:

- Use `qsub -k <discard option>`
- Use `#PBS Keep_Files=<discard option>`

For example, you can use either of the following to keep both standard output and standard error on the execution host:

```
qsub -k oe my_job
#PBS -k oe
```

3.3.5.1 Caveats for Keeping Files on Execution Host

- When a job finishes, if PBS created a job-specific staging and execution directory, PBS deletes the job-specific staging and execution directory, and all files in that directory. If you specified that `stdout` and/or `stderr` should be kept on the execution host, any files you specified are deleted as well.
- The `qsub -k` option overrides the `-o` and `-e` options. For example, if you specify `qsub -k o -o <path>`, `stdout` is kept on the execution host, and is not copied to the path you specified.

3.3.6 Writing Files Directly to Final Destination

If the MoM on the primary execution host can reach the final destination, she can write the job's standard output and standard error files to that destination. To be reachable, the final destination host and path must either be on the execution host, or be mapped from the primary execution host via the $usecp directive in the MoM configuration file. To specify that standard output and/or standard error should be written directly to their final destinations, use the `d` sub-option to the `-k` option to `qsub` or `qalter`. Indicate which files to write via the `e` and/or `o` suboptions.

For example, to directly write both output and error to their final destinations:

```
qsub -koed -o <output path> -e <error path> job.sh
```

To directly write output to its final destination, and let error go through normal spooling and staging:

```
qsub -kod -o <output path> job.sh
```

3.3.7 Changing Linux Job `umask`

On Linux, whenever your job stages or copies files or directories to the execution host, or writes `stdout` or `stderr` on the execution host, MoM uses `umask` to determine the permissions for the file or directory. If you do not specify a value for `umask`, MoM uses the system default. You can specify a value using the following methods:

- Use `qsub -W umask=<value>`
- Use `#PBS umask=<value>`

This does not apply when your job script creates files or directories.

In the following example, we set `umask` to *022*, to have files created with write permission for owner only. The desired permissions are `-rw-r--r--`.

```
qsub -W umask=022 my_job
#PBS -W umask=022
```

3.3.7.1 Caveats

This feature does not apply to Windows.

3.3.8 Troubleshooting File Delivery

File delivery is handled by MoM on the execution host. For a description of how file delivery works, see "Setting File Transfer Mechanism" on page 441 in the PBS Professional Administrator's Guide.

For troubleshooting file delivery, see "Troubleshooting File Transfer" on page 446 in the PBS Professional Administrator's Guide.

3.3.8.1 Non-delivery of Output

If the output of a job cannot be delivered to you, it is saved in a special directory named `PBS_HOME/undelivered` and mail is sent to you. The typical causes of non-delivery are:

1. The destination host is not trusted and you do not have a `.rhosts` file.
2. An improper path was specified.
3. A directory in the specified destination path is not writable.
4. Your `.cshrc` on the destination host generates output when executed.
5. The path specified by PBS_SCP in `pbs.conf` is incorrect.
6. The `PBS_HOME/spool` directory on the execution host does not have the correct permissions. This directory must have mode *1777 drwxrwxrwxt* (on Linux) or "Full Control" for "Everyone" (on Windows).

3.3.9 Caveats for Output and Error Files

3.3.9.1 Retaining Files on Execution Host

When PBS creates a job-specific staging and execution directory and you use the -k option to `qsub` or you specify *o* and/or *e* in the Keep_Files attribute, the files you requested kept on the execution host are deleted when the job-specific staging and execution directory is deleted at the end of the job.

3.3.9.2 Standard Output and Error Appended When Job is Rerun

If your job runs and writes to `stdout` or `stderr`, and then is rerun, meaning that another job with the same name is run, PBS appends the `stdout` of the second run to that of the first, and appends the `stderr` of the second run to that of the first.

3.3.9.3 Windows Mapped Drives and PBS

In Windows, when you map a drive, it is mapped locally to your session. The mapped drive cannot be seen by other processes outside of your session. A drive mapped on one session cannot be un-mapped in another session even if the user is the same. This has implications for running jobs under PBS. Specifically if you map a drive, `chdir` to it, and submit a job from that location, the vnode that executes the job may not be able to deliver the files back to the same location from which you issued `qsub`. The workaround is to tell PBS to deliver the files to a local, non-mapped, directory. Use the "`-o`" or "`-e`" options to `qsub` to specify the directory location for the job output and error files. For details see section 3.3.2, “Paths for Output and Error Files”, on page 44.

3.3.9.4 Harmless `csh` Error Message

If your login shell is `csh` the following message may appear in the standard output of a job:

```
Warning: no access to tty, thus no job control in this shell
```

This message is produced by many `csh` versions when the shell determines that its input is not a terminal. Short of modifying `csh`, there is no way to eliminate the message. Fortunately, it is just an informative message and has no effect on the job.

3.3.9.5 Interactive Jobs and File I/O

When an interactive job finishes, `stdout` and/or `stderr` may not have been copied back yet.

3.3.9.6 Write Permissions Required

- You must have write permission for any directory where you will copy `stdout` or `stderr`.
- Root must be able to write in `PBS_HOME/spool`.

4 Allocating Resources & Placing Jobs

4.1 What is a Vnode?

A virtual node, or vnode, is an abstract object representing a set of resources which form a usable part of a machine. This could be an entire host, or a nodeboard or a blade. A single host can be made up of multiple vnodes.

A host is any computer. Execution hosts used to be called nodes, and are still often called nodes outside of the PBS documentation. PBS views hosts as being composed of one or more vnodes.

PBS manages and schedules each vnode independently. Jobs run on one or more vnodes. Each vnode has its own set of attributes; see "Vnode Attributes" on page 320 of the PBS Professional Reference Guide.

4.1.1 Deprecated Vnode Types

All vnodes are treated alike, and are treated the same as what were once called "time-shared nodes". The types "time-shared" and "cluster" are deprecated. The `:ts` suffix is deprecated. It is silently ignored, and not preserved during rewrite.

The vnode attribute ntype was only used to distinguish between PBS and Globus vnodes. Globus can still send jobs to PBS, but PBS no longer supports sending jobs to Globus. The ntype attribute is read-only.

4.2 PBS Resources

4.2.1 Introduction to PBS Resources

In this section, "Introduction to PBS Resources", we will briefly cover the basics of PBS resources. For a thorough discussion, see "Using PBS Resources" on page 227 in the PBS Professional Administrator's Guide, especially sections 5.4 and 5.5. For a complete description of each PBS resource, see Chapter 5, "List of Built-in Resources", on page 259.

PBS resources represent things such as CPUs, memory, application licenses, switches, scratch space, and time. They can also represent whether or not something is true, for example, whether a machine is dedicated to a particular project.

PBS provides a set of built-in resources, and allows the administrator to define additional custom resources. Custom resources are used for application licenses, scratch space, etc., and are defined by the administrator. Custom resources are used the same way built-in resources are used. PBS supplies the following types of resources:

Boolean

Name of Boolean resource is a string.

Values:

TRUE, True, true, T, t, Y, y, 1

FALSE, False, false, F, f, N, n, 0

Duration

A period of time, expressed either as

An integer whose units are seconds

or

[[hours:]minutes:]seconds[.milliseconds]

in the form:

[[[HH]HH:]MM:]SS[.milliseconds]

Milliseconds are rounded to the nearest second.

Float

Floating point. Allowable values: [+-] 0-9 [[0-9] ...][.][[0-9] ...]

Long

Long integer. Allowable values: 0-9 [[0-9] ...], and + and -

<queue name>@<server name>

Size

Number of bytes or words. The size of a word is 64 bits.

Format: *<integer>[<suffix>]*

where *suffix* can be one of the following:

Table 4-1: Size in Bytes

Suffix	Meaning	Size
b or w	Bytes or words	1
kb or kw	Kilobytes or kilowords	2 to the 10th, or 1024
mb or mw	Megabytes or megawords	2 to the 20th, or 1,048,576
gb or gw	Gigabytes or gigawords	2 to the 30th, or 1,073,741,824
tb or tw	Terabytes or terawords	2 to the 40th, or 1024 gigabytes
pb or pw	Petabytes or petawords	2 to the 50th, or 1,048,576 gigabytes

Default: *bytes*

Note that a scheduler rounds all resources of type size up to the nearest kb.

String

Any character, including the space character.

Only one of the two types of quote characters, " or ', may appear in any given value.

Values:[_a-zA-Z0-9][[-_a-zA-Z0-9 ! " # $ % ´ ( ) * + , - . / : ; < = > ? @ [\ ] ^ _ ' { | } ~] ...]

String resource values are case-sensitive. No limit on length.

String Array

Comma-separated list of strings.

Strings in string_array may not contain commas. No limit on length.

Python type is *str*.

A string array resource with one value works exactly like a string resource.

See "Resources Built Into PBS" on page 265 of the PBS Professional Reference Guide for a listing of built-in resources.

For some systems, PBS creates specific custom resources.

The administrator can specify which resources are available at the server, each queue, and each vnode. Resources defined at the queue or server level apply to an entire job. Resources defined at the vnode level apply only to the part of the job running on that vnode.

Jobs can request resources. The scheduler matches requested resources with available resources, according to rules defined by the administrator. PBS always places jobs where it finds the resources requested by the job. PBS will not place a job where that job would use more resources than PBS thinks are available. For example, if you have two jobs, each requesting 1 CPU, and you have one vnode with 1 CPU, PBS will run only one job at a time on the vnode.

PBS can enforce limits on resource usage by jobs; see section 4.5, "Limits on Resource Usage", on page 63.

4.2.2 Glossary

Chunk

A set of resources allocated as a unit to a job. Specified inside a selection directive. All parts of a chunk come from the same host. In a typical MPI (Message-Passing Interface) job, there is one chunk per MPI process.

Chunk-level resource, host-level resource

A resource that is available at the host level, for example, CPUs or memory. Chunk resources are requested inside of a selection statement. The resources of a chunk are to be applied to the portion of the job running in that chunk.

Chunk resources are requested inside a select statement.

Job-wide resource, server resource, queue resource

A job-wide resource, also called a server-level or queue-level resource, is a resource that is available to the entire job at the server or queue.

A job-wide resource is available to be consumed or matched at the server or queue if you set the server or queue resources_available.<resource name> attribute to the available or matching value. For example, you can define a custom resource called *FloatingLicenses* and set the server's resources_available.FloatingLicenses attribute to the number of available floating licenses.

Examples of job-wide resources are shared scratch space, application licenses, or walltime.

A job can request a job-wide resource for the entire job, but not for individual chunks.

4.3 Requesting Resources

Your job can request resources that apply to the entire job, or resources that apply to job chunks. For example, if your entire job needs an application license, your job can request one job-wide license. However, if one job process needs two CPUs and another needs 8 CPUs, your job can request two chunks, one with two CPUs and one with eight CPUs. Your job cannot request the same resource in a job-wide request and a chunk-level request.

PBS supplies resources such as walltime that can be used only as job-wide resources, and other resources, such as ncpus and mem, that can be used only as chunk resources. A resource is either job-wide or chunk-level, but not both. The description of each resource tells you which way to use the resource; see "List of Built-in Resources" on page 259 of the PBS Professional Reference Guide.

We will cover the details of requesting resources in section 4.3.2, "Requesting Job-wide Resources", on page 54 and section 4.3.3, "Requesting Resources in Chunks", on page 55.

4.3.1 Quick Summary of Requesting Resources

Job-wide resources are requested in *<resource neme>=<value>* pairs. You can request job-wide resources using any of the following:

- The `qsub -l <resource name>=<value>` option

  You can request multiple resources, using either format:

  `-l <resource>=<value>,<resource>=<value>`

  `-l <resource>=<value> -l <resource>=<value>`

- One or more `#PBS -l <resource name>=<value>` directives

Chunk resources are requested in *chunk specifications* in a *select statement*. You can request chunk resources using any of the following:

- The `qsub -l select=[N:][<chunk specification>][+[N:]<chunk specification>]` option
- A `#PBS -l select=[N:][<chunk specification>][+[N:]<chunk specification>]` directive

Format for requesting both job-wide and chunk resources:

`qsub ...` (non-resource portion of job)
`-l <resource>=<value>` (this is the job-wide request)
`-l select=<chunk>[+<chunk>]` (this is the selection statement)

PBS supplies several commands that you can use to request resources or alter resource requests:

- The `qsub` command (both via command-line and in PBS directives)
- The `pbs_rsub` command (via command-line only)
- The `qalter` command (via command-line only)

4.3.2 Requesting Job-wide Resources

Your job can request resources that apply to the entire job in *job-wide* resource requests. A job-wide resource is designed to be used by the entire job, and is available at the server or a queue, but not at the host level. Job-wide resources are used for requesting floating application licenses or other resources not tied to specific vnodes, such as cput and walltime.

Job-wide resources are requested outside of a selection statement, in this form:

-l <resource name>=<value>[,<resource name>=<value> ...]

A resource request "outside of a selection statement" means that the resource request comes after "`-l`", but not after "`-lselect=`". In other words, you cannot request a job-wide resource in chunks.

For example, to request one hour of walltime for a job:

-l walltime=1:00:00

You can request job-wide resources using any of the following:

- The `qsub -l <resource name>=<value>` option

You can request multiple resources, using either format:

```
-l <resource>=<value>,<resource>=<value>
-l <resource>=<value> -l <resource>=<value>
```

- One or more `#PBS -l <resource name>=<value>` directives

4.3.3 Requesting Resources in Chunks

A *chunk* specifies the value of each resource in a set of resources which are to be allocated as a unit to a job. It is the smallest set of resources to be allocated to a job. All of a chunk is taken from a single host. One chunk may be broken across vnodes, but all participating vnodes must be from the same host.

Your job can request chunk resources, which are resources that apply to the host-level parts of the job. Host-level resources can only be requested as part of a chunk. Server or queue resources cannot be requested as part of a chunk. A chunk resource is used by the part of the job running on that chunk, and is available at the host level. Chunks are used for requesting host-related resources such as CPUs, memory, and architecture.

Chunk resources are requested inside a select statement. A select statement has this form:

-l select=[N:]<chunk>[+[N:]<chunk> ...]

Now, we'll explain the details. A single chunk is requested using this form:

-l select=<resource name>=<value>[:<resource name>=<value>...]

For example, one chunk might have 2 CPUs and 4GB of memory:

```
-l select=ncpus=2:mem=4gb
```

To request multiples of a chunk, prefix the chunk specification by the number of chunks:

-l select=[<number of chunks>]<chunk specification>

For example, to request six of the previous chunk:

```
-l select=6:ncpus=2:mem=4gb
```

If you don't specify *N*, the number of chunks, it is taken to be *1*.

To request different chunks, concatenate the chunks using the plus sign ("+"):

-l select=[<number of chunks>]<chunk specification>+[<number of chunks>]<chunk specification>

For example, to request two sets of chunks where one set of 6 chunks has 2 CPUs per chunk, and one set of 3 chunks has 8 CPUs per chunk, and both sets have 4GB of memory per chunk:

```
-l select=6:ncpus=2:mem=4gb+3:ncpus=8:mem=4GB
```

No spaces are allowed between chunks.

You must specify all your chunks in a single select statement.

You can request chunk resources using any of the following:

- The `qsub -l select=[N:][<chunk specification>][+[N:]<chunk specification>]` option
- A `#PBS -l select=[N:][<chunk specification>][+[N:]<chunk specification>]` directive

4.3.4 Requesting Boolean Resources

A resource request can specify whether a Boolean resource should be *True* or *False*.

Example 4-1: Some vnodes have green=*True* and some have red=*True*, and you want to request two vnodes, each with one CPU, all green and no red:

```
-l select=2:green=true:red=false:ncpus=1
```

Example 4-2: This job script snippet has a job-wide request for walltime and a chunk request for CPUs and memory where the Boolean resource HasMyApp is *True*:

```
#PBS -l walltime=1:00:00
#PBS -l select=ncpus=4:mem=400mb:HasMyApp=true
```

Keep in mind the difference between requesting a vnode-level boolean and a job-wide boolean:

```
qsub -l select=1:green=True
```

requests a vnode with green set to *True*. However,

```
qsub -l green=True
```

requests green set to *True* on the server and/or queue.

4.3.5 Requesting Application Licenses

Application licenses are managed as resources defined by your PBS administrator. PBS doesn't actually check out the licenses; the application being run inside the job's session does that.

4.3.5.1 Requesting Floating Application Licenses

A site-wide floating license is typically configured as a server-level, job-wide resource.

To request a job-wide application license called AppF, use:

```
qsub -l AppF=<number of licenses> <other qsub arguments>
```

If only certain hosts can run the application, they will typically have a host-level Boolean resource set to *True*.

The job-wide resource AppF is a numerical resource indicating the number of licenses available at the site. The host-level Boolean resource haveAppF indicates whether a given host can run the application. To request the application license and the vnodes on which to run the application:

```
qsub  -l AppF=<number of licenses> <other qsub arguments>
      -l select=haveAppF=True
```

PBS queries the license server to find out how many floating licenses are available at the beginning of each scheduling cycle. PBS doesn't actually check out the licenses, the application being run inside the job's session does that.

4.3.5.2 Requesting Node-locked Application Licenses

Node-locked application licenses are available at the vnode(s) that are licensed for the application. These are host-level (chunk) resources that are requested inside of a select statement.

4.3.5.2.i Requesting Per-host Node-locked Application Licenses

Per-host node-locked application licenses are typically configured as a Boolean resource that indicates whether or not the required license is available at that host.

When requesting Boolean-valued per-host node-locked licenses, request one per host. Format:

qsub -l select=<Boolean resource name>=true:<rest of chunk specification>

Example 4-3: The Boolean resource runsAppA specifies whether this vnode has the necessary license. To request a host with a per-host node-locked license for AppA in one chunk:

```
qsub -l select=1:runsAppA=1 <job script>
```

4.3.5.2.ii Requesting Per-use Node-locked Application Licenses

Per-use node-locked application licenses are typically configured as a consumable numeric resource so that the host(s) that run the application have the number of licenses that can be used at one time.

When requesting numerical per-use node-locked licenses, request the required number of licenses for each host:

qsub -l select=<consumable resource name>=<required amount>:<rest of chunk specification>

Example 4-4: The consumable resource named AppB indicates the number of available per-use application licenses on a host. To request a host with a per-use node-locked license for AppB, where you'll run one instance of AppB on two CPUs in one chunk:

```
qsub -l select=1:ncpus=2:AppB=1
```

4.3.5.2.iii Requesting Per-CPU Node-locked Application Licenses

Per-CPU node-locked licenses are typically arranged so that the host has one license for each licensed CPU. The PBS administrator configures a consumable numerical resource indicating the number of available licenses.

You must request one license for each CPU. When requesting numerical per-use node-locked licenses, request the required number of licenses for each host:

qsub -l select=<per-CPU resource name>=<required amount>:<rest of chunk specification>

Example 4-5: The numerical consumable resource named AppC indicates the number of available per-CPU licenses. To request a host with two per-CPU node-locked licenses for AppC, where you'll run a job using two CPUs in one chunk:

```
qsub -l select=1:ncpus=2:AppC=2
```

4.3.6 Requesting Scratch Space

Scratch space on a machine is configured as a host-level dynamic resource. Ask your administrator for the name of the scratch space resource.

When requesting scratch space, include the resource in your chunk request:

-l select=<scratch resource name>=<amount of scratch needed>:<rest of chunk specification>

Example 4-6: Your administrator has named the scratch resource "dynscratch". To request 10MB of scratch space in one chunk:

```
-l select=1:ncpus=N:dynscratch=10MB
```

4.3.7 Requesting GPUs

Your PBS job can request GPUs. How you request GPUs depends on whether PBS uses cgroups to manage GPUs; check with your administrator.

4.3.7.1 Requesting GPUs Managed via Cgroups

Recommended: On Linux only, PBS can be configured to use cgroups to fence GPUs off, so that when your job requests GPUs it automatically gets exclusive use of its GPUs. You don't have to request exclusivity. When PBS uses cgroups to manage GPUs, you request the number of GPUs you want via the ngpus resource:

qsub -l select=ngpus=<value>:<rest of chunk specification>

When GPUs are managed via cgroups, jobs requesting memory will use that amount both for physical memory and for swap. For example, a job that requests 20GB and uses 16GB but reads a 50GB file can only swap 4GB at a time. So if a job requires 32GB of application memory but also requires 5GB of private file cache to perform adequately, then it needs to request 37GB.

4.3.7.2 Requesting GPUs Not Managed via Cgroups

On Windows or Linux, when PBS is not using cgroups to manage GPUs, your administrator can configure PBS to support any of the following:

- ("Basic GPU scheduling") Job uses non-specific GPUs and exclusive use of a node
- ("Advanced GPU scheduling") Job uses non-specific GPUs and shared use of a node
- ("Advanced GPU scheduling") Job uses specific GPUs and either shared or exclusive use of a node

4.3.7.2.i Binding to GPUs

PBS Professional allocates GPUs, but does not bind jobs to any particular GPU; the application itself, or the CUDA library, is responsible for the actual binding.

4.3.7.2.ii Requesting Non-specific GPUs and Exclusive Use of Node

When your site uses "basic GPU scheduling", if your job needs GPUs, but does not require specific GPUs, and can request exclusive use of GPU nodes, you can request GPUs the same way you request CPUs.

Your administrator can set up a resource to represent the GPUs on a node. We recommend that the GPU resource is called *ngpus*.

When requesting GPUs in this manner, your job should request exclusive use of the node to prevent other jobs being scheduled on its GPUs.

qsub -l select=ngpus=<value>:<rest of chunk specification> -lplace=excl

Example 4-7: To submit the job named "*my_gpu_job*", requesting one node with two GPUs and one CPU, and exclusive use of the node:

```
qsub -lselect=1:ncpus=1:ngpus=2 -lplace=excl my_gpu_job
```

It is up to the application or CUDA to bind the GPUs to the application processes.

4.3.7.2.iii Requesting Non-specific GPUs and Shared Use of Node

When your site uses "advanced GPU scheduling", your administrator can configure PBS to allow your job to use non-specific GPUs on a node while sharing GPU nodes. In this case, your administrator puts each GPU in its own vnode.

Your administrator can configure a resource to represent GPUs. We recommend that the GPU resource is called *ngpus*.

Your administrator can configure each GPU vnode so it has a resource containing the device number of the GPU. We recommend that this resource is called *gpu_id*.

Example 4-8: To submit the job named "*my_gpu_job*", requesting two GPUs and one CPU, and shared use of the node:

```
qsub -lselect=1:ncpus=1:ngpus=2 -lplace=shared my_gpu_job
```

When a job is submitted requesting any GPU, the PBS scheduler looks for a vnode with an available GPU and assigns that vnode to the job. Since there is a one-to-one correspondence between GPUs and vnodes, the job can determine the gpu_id of that vnode. Finally, the application can use the appropriate CUDA call to bind the process to the allocated GPU.

4.3.7.2.iv Requesting Specific GPUs

When your site uses "advanced GPU scheduling", your job can request one or more specific GPUs. This allows you to run applications on the GPUs for which the applications are written.

Your administrator can set up a resource to allow jobs to request specific GPUs. We recommend that the GPU resource is called *gpu_id*.

When you request specific GPUs, specify the GPU that you want for each chunk:

qsub -l select=gpu_id=<GPU ID>:<rest of chunk specification>

Example 4-9: To request 4 vnodes, each with GPU with ID *0*:

```
qsub -lselect=4:ncpus=1:ngpus=1:gpu_id=gpu0 my_gpu_job
```

When a job is submitted requesting specific GPUs, the PBS scheduler assigns the vnode with the resource containing that gpu_id to the job. The application can use the appropriate CUDA call to bind the process to the allocated GPU.

4.3.7.3 Viewing GPU Information for Nodes

You can find the number of GPUs available and assigned on execution hosts via the `pbsnodes` command. See section 4.6, "Viewing Resources", on page 65.

4.3.8 Caveats and Restrictions on Requesting Resources

4.3.8.1 Caveats and Restrictions for Specifying Resource Values

- Resource values which contain commas, quotes, plus signs, equal signs, colons, or parentheses must be quoted to PBS. The string must be enclosed in quotes so that the command (e.g. `qsub`, `qalter`) will parse it correctly.
- When specifying resources via the command line, any quoted strings must be escaped or enclosed in another set of quotes. This second set of quotes must be different from the first set, meaning that double quotes must be enclosed in single quotes, and vice versa.
- If a string resource value contains spaces or shell metacharacters, enclose the string in quotes, or otherwise escape the space and metacharacters. Be sure to use the correct quotes for your shell and the behavior you want.

4.3.8.2 Warning About NOT Requesting walltime

If your job does not request a walltime, and there is no default for walltime, your job is treated as if it had requested a very, very long walltime. Translation: the scheduler will have a hard time finding a time slot for your job. Remember, the administrator may schedule dedicated time for the entire PBS complex once a year, for upgrading, etc. In this case, your job will never run. We recommend requesting a reasonable walltime for your job.

4.3.8.3 Caveats for Jobs Requesting Undefined Resources

If you submit a job that requests a job-wide or host-level resource that is undefined, the job is not rejected at submission; instead, it is aborted upon being enqueued in an execution queue, if the resources are still undefined. This preserves backward compatibility.

4.3.8.4 Matching Resource Requests with Unset Resources

When job resource requests are being matched with available resources, a numerical resource that is unset on a host is treated as if it were zero, and an unset string cannot satisfy a request. An unset Boolean resource is treated as if it were set to "*False*". An unset resource at the server or queue is treated as if it were infinite.

4.3.8.5 Caveat for Invisible or Unrequestable Resources

Your administrator may define custom resources which restricted, so that they are invisible, or are visible but unrequestable. Custom resources which were created to be invisible or unrequestable cannot be requested or altered. The following is a list of the commands normally used to view or request resources or modify resource requests, and their limitations for restricted resources:

`pbsnodes`
: Job submitters cannot view restricted host-level custom resources.

`pbs_rstat`
: Job submitters cannot view restricted reservation resources.

`pbs_rsub`
: Job submitters cannot request restricted custom resources for reservations.

`qalter`
: Job submitters cannot alter a restricted resource.

`qmgr`
: Job submitters cannot print or list a restricted resource.

`qselect`
: Job submitters cannot specify restricted resources via `-l Resource_List.`

`qsub`
: Job submitters cannot request a restricted resource.

`qstat`
: Job submitters cannot view a restricted resource.

4.3.8.6 Warning About Requesting Tiny Amounts of Memory

The smallest unit of memory you can request is 1KB. If you request 400 bytes, you get 1KB. If you request 1400 bytes, you get 2KB.

4.3.8.7 Maximum Length of Job Submission Command Line

The maximum length of a command line in PBS is 4095 characters. When you submit a job using the command line, your select and place statements, and the rest of your command line, must fit within 4095 characters.

4.3.8.8 Only One select Statement Per Job

You can include at most one select statement per job submission.

4.3.8.9 The software Resource is Job-wide

The built-in resource "software" is not a vnode-level resource. See "Resources Built Into PBS" on page 265 of the PBS Professional Reference Guide.

4.3.8.10 Do Not Mix Old and New Syntax

Do not mix old and new syntax when requesting resources. See section 4.8, “Backward Compatibility”, on page 72 for a description of old syntax.

4.4 How Resources are Allocated to Jobs

Resources are allocated to your job when the job explicitly requests them, and when PBS applies defaults.

Jobs explicitly request resources either at the vnode level in chunks defined in a selection statement, or in job-wide resource requests. We will cover requesting resources in section 4.3.3, “Requesting Resources in Chunks”, on page 55 and section 4.3.2, “Requesting Job-wide Resources”, on page 54.

The administrator can set default resources at the server and at queues, so that a job that does not request a resource at submission time ends up being allocated the default value for that resource. We will cover default resources in section 4.4.1, “Applying Default Resources”, on page 61.

The administrator can also specify default arguments for `qsub` so that jobs automatically request certain resources. Resource values explicitly requested by your job override any `qsub` defaults. See “qsub” on page 216 of the PBS Professional Reference Guide.

4.4.1 Applying Default Resources

PBS applies resource defaults only where the job has not explicitly requested a value for a resource.

Job-wide and per-chunk resources are applied, with the following order of precedence, via the following:

1. Resources that are explicitly requested via `-l <resource>=<value>` and `-l select=<chunk>`
2. Default `qsub` arguments
3. The queue's default_chunk.<resource>
4. The server's default_chunk.<resource>
5. The queue's resources_default.<resource>
6. The server's resources_default.<resource>
7. The queue's resources_max.<resource>
8. The server's resources_max.<resource>

4.4.1.1 Applying Job-wide Default Resources

The explicit job-wide resource request is checked first against default `qsub` arguments, then against queue resource defaults, then against server resource defaults. Any default job-wide resources not already in the job's resource request are added. PBS applies job-wide default resources defined in the following places, in this order:

- Via `qsub`: The server's default_qsub_arguments attribute can include any requestable job-wide resources.
- Via the queue: Each queue's resources_default attribute defines each queue-level job-wide resource default in resources_default.<resource>.
- Via the server: The server's resources_default attribute defines each server-level job-wide resource default in resources_default.<resource>.

4.4.1.2 Applying Per-chunk Default Resources

For each chunk in the job's selection statement, first qsub defaults are applied, then queue chunk defaults are applied, then server chunk defaults are applied. If the chunk request does not include a resource listed in the defaults, the default is added. PBS applies default chunk resources in the following order:

- Via qsub: The server's default_qsub_arguments attribute can include any requestable chunk resources.
- Via the queue: Each queue's default_chunk attribute defines each queue-level chunk resource default in default_chunk.<resource>.
- Via the server: The server's default_chunk attribute defines each server-level chunk resource default in default_chunk.<resource>.

Example 4-10: Applying chunk defaults: if the queue in which the job is enqueued has the following defaults defined:

```
default_chunk.ncpus=1
default_chunk.mem=2gb
```

A job submitted with this selection statement:

```
select=2:ncpus=4+1:mem=9gb
```

The job has this specification after the default_chunk elements are applied:

select=2:ncpus=4:*mem=2gb*+1:*ncpus=1*:mem=9gb.

In this example, *mem=2gb* and *ncpus=1* are inherited from default_chunk.

4.4.1.3 Caveat for Moving Jobs From One Queue to Another

If the job is moved from the current queue to a new queue, any default resources in the job's resource list that were contributed by the current queue are removed. This includes a select specification and place directive generated by the rules for conversion from the old syntax. If a job's resource is unset (undefined) and there exists a default value at the new queue or server, that default value is applied to the job's resource list. If either select or place is missing from the job's new resource list, it will be automatically generated, using any newly inherited default values.

Given the following set of queue and server default values:

Server

```
resources_default.ncpus=1
```

Queue QA

```
resources_default.ncpus=2
default_chunk.mem=2gb
```

Queue QB

```
default_chunk.mem=1gb
```

no default for ncpus

The following examples illustrate the equivalent select specification for jobs submitted into queue QA and then moved to (or submitted directly to) queue QB:

qsub -l ncpus=1 -lmem=4gb

In QA: select=1:ncpus=1:mem=4gb

No defaults need be applied

In QB: select=1:ncpus=1:mem=4gb

No defaults need be applied

qsub -l ncpus=1

In QA: select=1:ncpus=1:mem=2gb

Picks up 2gb from queue default chunk and 1 ncpus from qsub

In QB: select=1:ncpus=1:mem=1gb

Picks up 1gb from queue default chunk and 1 ncpus from qsub

qsub -lmem=4gb

In QA: select=1:ncpus=2:mem=4gb

Picks up 2 ncpus from queue level job-wide resource default and 4gb mem from qsub

In QB: select=1:ncpus=1:mem=4gb

Picks up 1 ncpus from server level job-wide default and 4gb mem from qsub

qsub -lnodes=4

In QA: select=4:ncpus=1:mem=2gb

Picks up a queue level default memory chunk of 2gb. (This is not 4:ncpus=2 because in prior versions, "nodes=x" implied 1 CPU per node unless otherwise explicitly stated.)

In QB: select=4:ncpus=1:mem=1gb

(In prior versions, "nodes=x" implied 1 CPU per node unless otherwise explicitly stated, so the ncpus=1 is not inherited from the server default.)

qsub -l mem=16gb -lnodes=4

In QA: select=4:ncpus=1:mem=4gb

(This is not 4:ncpus=2 because in prior versions, "nodes=x" implied 1 CPU per node unless otherwise explicitly stated.)

In QB: select=4:ncpus=1:mem=4gb

(In prior versions, "nodes=x" implied 1 CPU per node unless otherwise explicitly stated, so the ncpus=1 is not inherited from the server default.)

4.5 Limits on Resource Usage

Jobs are assigned limits on the amount of resources they can use. These limits apply to how much the whole job can use (job-wide limit) and to how much the job can use at each host (host limit). Limits are applied only to resources the job requests or inherits.

Your administrator can configure PBS to enforce limits on mem and ncpus, but the other limits are always enforced.

If you want to make sure that your job does not exceed a given amount of some resource, request that amount of the resource.

4.5.1 Enforceable Resource Limits

Limits can be enforced on the following resources:

Table 4-2: Enforceable Resource Limits

Resource Name	Where Specified	Where Enforced	Always Enforced?
cput	Host	Host	Always
mem	Host	Host	Optional
ncpus	Host	Host	Optional

Table 4-2: Enforceable Resource Limits

Resource Name	Where Specified	Where Enforced	Always Enforced?
pcput	Job-wide	Per-process	Always
pmem	Job-wide	Per-process	Always
pvmem	Job-wide	Per-process	Always
vmem	Host	Host	Always
walltime	Job-wide	Job-wide	Always

4.5.2 Origins of Resource Limits

Limits are derived from both requested resources and applied default resources. Resource limits are derived in the order shown in section 4.4.1, “Applying Default Resources”, on page 61.

4.5.3 Job-wide Resource Limits

Job-wide resource limits set a limit for per-job resource usage. Job resource limits are derived from job-wide resources and from totals of per-chunk consumable resources. Limits are derived from explicitly requested resources and default resources.

Job-wide resource limits that are derived from from sums of all chunks override those that are derived from job-wide resources.

Example 4-11: Job-wide limits are derived from sums of chunks. With the following chunk request:

```
qsub -lselect=2:ncpus=3:mem=4gb:arch=linux
```

The following job-wide limits are derived:

ncpus=6

mem=8gb

4.5.4 Per-chunk Resource Limits

Each chunk's per-chunk limits determine how much of any resource can be used at that host. PBS sums the chunk limits at each host, and uses that sum as the limit at that resource. Per-chunk resource usage limits are the amount of per-chunk resources allocated to the job, both from explicit requests and from defaults.

4.5.4.1 Effects of Limits

If a running job exceeds its limit for walltime, the job is terminated.

If any of the job's processes exceed the limit for pcput, pmem, or pvmem, the job is terminated.

If any of the host limits for mem, ncpus, cput, or vmem is exceeded, the job is terminated. These are host-level limits, so if for example your job has two chunks on one host, and the processes on one chunk exceed one of these limits, but the processes on the other are under the chunk limit, the job can continue to run as long as the total used for both chunks is less than the host limit.

4.5.5 Examples of Memory Limits

Your administrator may choose to enforce memory limits. If this is the case, the memory used by the entire job cannot exceed the amount in Resource_List.mem, and the memory used at any host cannot exceed the sum of the chunks on that host. For the following examples, assume the following:

The queue has these settings:

```
resources_default.mem=200mb
default_chunk.mem=100mb
```

Example 4-12: A job requesting `-l select=2:ncpus=1:mem=345mb` uses 345mb from each of two vnodes and has a job-wide limit of 690mb (2 * 345). The job's Resource_List.mem shows *690mb*.

Example 4-13: A job requesting `-l select=2:ncpus=2` takes 100mb via default_chunk from each vnode and has a job-wide limit of 200mb (2 * 100mb). The job's Resource_List.mem shows *200mb*.

Example 4-14: A job requesting `-l ncpus=2` takes 200mb (inherited from resources_default and used to create the select specification) from one vnode and has a job-wide limit of 200mb. The job's Resource_List.mem shows *200mb*.

Example 4-15: A job requesting `-lnodes=2` inherits 200mb from resources_default.mem which becomes the job-wide limit. The memory is taken from the two vnodes, half (100mb) from each. The generated select specification is `2:ncpus=1:mem=100mb`. The job's Resource_List.mem shows *200mb*.

4.6 Viewing Resources

You can look at the resources on the server, queue, and vnodes. You can also see what resources are allocated to and used by your job.

4.6.1 Viewing Server, Queue, and Vnode Resources

To see server resources:

```
qstat - Bf
```

To see queue resources:

```
qstat -Qf
```

To see vnode resources, use any of the following:

```
qmgr -c "list node <vnode name> <attribute name>"
pbsnodes -av
pbsnodes [<host list>]
```

Look at the following attributes:

resources_available.<resource name>

(Server, queue, vnode) Total amount of the resource available at the server, queue, or vnode; does not take into account how much of the resource is in use.

resources_default.<resource name>

(Server, queue) Default value for job-wide resource. This amount is allocated to job if job does not request this resource. Queue setting overrides server setting.

resources_max.<resource name>

(Server, queue) Maximum amount that a single job can request. Queue setting overrides server setting.

resources_min.<resource name>

(Queue) Minimum amount that a single job can request.

resources_assigned.<resource name>

(Server, queue, vnode) Total amount of the resource that has been allocated to running and exiting jobs and reservations at the server, queue, or vnode.

4.6.2 Viewing Job Resources

To see the resources allocated to or used by your job:

```
qstat -f
```

Look at the following job attributes:

Resource_List.<resource name>

The amount of the resource that has been allocated to the job, including defaults.

resources_used.<resource name>

The amount of the resource used by the job.

4.6.2.1 Resources Shown in Resource_List Job Attribute

When your job requests a job-wide resource or any of certain built-in host-level resources, the value requested is stored in the job's Resource_List attribute, as Resource_List.<resource name>=<value>. When you request a built-in host-level resource inside multiple chunks, the value in Resource_List is the sum over all of the chunks for that resource. For a list of the resources that can appear in Resource_List, see section 5.9.2, "Resources Requested by Job", on page 241 of the PBS Professional Administrator's Guide.

If your administrator has defined default values for any of those resources, and your job has inherited any defaults, those defaults control the value shown in the Resource_List attribute.

4.7 Specifying Job Placement

You can specify how your job should be placed on vnodes. You can choose to place each chunk on a different host, or a different vnode, or your job can use chunks that are all on one host. You can specify that all of the job's chunks should share a value for some resource.

Your job can request exclusive use of each vnode, or shared use with other jobs. Your job can request exclusive use of its hosts.

We will cover the basics of specifying job placement in the following sections. For details on placing chunks for an MPI job, see "Submitting Multiprocessor Jobs".

4.7.1 Using the place Statement

You use the *place* statement to specify how the job's chunks are placed.

The place statement can contain the following elements in any order:

-l place=[<arrangement>][: <sharing>][: <grouping>]

where

arrangement

Whether this chunk is willing to share this vnode or host with other chunks from the same job. One of *free* | *pack* | *scatter* | *vscatter*

sharing

Whether this this chunk is willing to share this vnode or host with other jobs. One of *excl* | *shared* | *exclhost*

grouping

Whether the chunks from this job should be placed on vnodes that all have the same value for a resource. Can have only one instance of *group=<resource name>*

and where

Table 4-3: Placement Modifiers

Modifier	Meaning
free	Place job on any vnode(s)
pack	All chunks will be taken from one host
scatter	Only one chunk is taken from any host
vscatter	Only one chunk is taken from any vnode. Each chunk must fit on a vnode.
excl	Only this job uses the vnodes chosen
exclhost	The entire host is allocated to this job
shared	This job can share the vnodes chosen
group=<resource>	Chunks will be placed on vnodes according to a resource shared by those vnodes. This resource must be a string or string array. All vnodes in the group must have a common value for the resource.

The place statement may be not be used without the select statement.

The place statement may not begin with a colon.

4.7.1.1 Specifying Arrangement of Chunks

To place your job's chunks wherever they fit:

```
-l place=free
```

To place all of the job's chunks on a single host:

```
-l place=pack
```

To place each chunk on its own host:

```
-l place=scatter
```

To place each chunk on its own vnode:

```
-l place=vscatter
```

4.7.1.1.i Caveats and Restrictions for Arrangement

- For all arrangements except *vscatter*, chunks cannot be split across hosts, but they can be split across vnodes on the same host. If a job does not request *vscatter* for its arrangement, any chunk can be broken across vnodes. This means that one chunk could be taken from more than one vnode.
- If the job requests *vscatter* for its arrangement, no chunk can be larger than a vnode, and no chunk can be split across vnodes. This behavior is different from other values for arrangement, where chunks can be split across vnodes.

4.7.1.2 Specifying Shared or Exclusive Use of Vnodes

Each vnode can be allocated exclusively to one job, or its resources can be shared among jobs. Hosts can also be allocated exclusively to one job, or shared among jobs.

How vnodes are allocated to jobs is determined by a combination of the vnode's sharing attribute and the job's resource request. The possible values for the vnode sharing attribute, and how they interact with a job's placement request, are described in "sharing" on page 324 of the PBS Professional Reference Guide. The following table expands on this:

Table 4-4: How Vnode sharing Attribute Affects Vnode Allocation

Value of Vnode sharing Attribute	Effect on Allocation
not set	The job's arrangement request determines how vnodes are allocated to the job. If there is no specification, vnodes are shared.
default_share	Vnodes are shared unless the job explicitly requests exclusive use of the vnodes.
default_excl	Vnodes are allocated exclusively to the job unless the job explicitly requests shared allocation.
default_exclhost	All vnodes from this host are allocated exclusively to the job, unless the job explicitly requests shared allocation.
ignore_excl	Vnodes are shared, regardless of the job's request.
force_excl	Vnodes are allocated exclusively to the job, regardless of the job's request.
force_exclhost	All vnodes from this host are allocated exclusively to the job, regardless of the job's request.

If a vnode is allocated exclusively to a job, all of its resources are assigned to the job. The state of the vnode becomes *job-exclusive*. No other job can use the vnode.

If a host is to be allocated exclusively to one job, all of the host must be used: if any vnode from a host has its sharing attribute set to either *default_exclhost* or *force_exclhost*, all vnodes on that host must have the same value for the sharing attribute.

If your job requests exclusive placement, and it is in a reservation, the reservation must also request exclusive placement via `-l place=excl`.

To see the value for a vnode's sharing attribute, you can do either of the following:

- Use `qmgr`:
  `Qmgr: list node <vnode name> sharing`
- Use `pbsnodes`:
  `pbsnodes -av`

4.7.1.3 Grouping on a Resource

You can specify that all of the chunks for your job should run on vnodes that have the same value for a selected resource.

To group your job's chunks this way, use the following format:

-l place=group=<resource name>

where *resource name* is a string or string array.

The value of the resource can be one or more strings at each vnode, but there must be one string that is the same for each vnode. For example, if the resource is *router*, the value can be "*r1i0,r1*" at one vnode, and "*r1i1,r1*" at another vnode, and these vnodes can be grouped because they share the string "*r1*".

Using the method of grouping on a resource, you cannot specify what the value of the resource should be, only that all vnodes have the same value. If you need the resource to have a specific value, specify that value in the description of the chunks.

4.7.1.3.i Grouping vs. Placement Sets

Your administrator may define placement sets for your site. A placement set is a group of vnodes that share a value for a resource. By default, placement sets attempt to group vnodes that are "close to" each other. If your job doesn't request a specific placement, and placement sets are defined, your job may automatically run in a placement set. See "Placement Sets" on page 167 in the PBS Professional Administrator's Guide.

If your job requests grouping by a resource, using *place=group=resource*, the chunks are placed as requested and placement sets are ignored.

If your job requests grouping but no group contains the required number of vnodes, grouping is ignored.

4.7.2 How the Job Gets its Place Statement

If the administrator has defined default values for arrangement, sharing, and grouping, each job inherits these unless it explicitly requests at least one. That means that if your job requests arrangement, but not sharing or grouping, it will not inherit values for sharing or grouping. For example, the administrator sets a default of `place=pack:exclhost:group=host`. Job A requests `place=free`, but doesn't specify sharing or grouping, so Job A does not inherit sharing or grouping. Job B does not request any placement, so it inherits all three.

The place statement can be specified, in order of precedence, via:

1. Explicit placement request in `qalter`
2. Explicit placement request in `qsub`
3. Explicit placement request in PBS job script directives
4. Default `qsub` place statement
5. Queue default placement rules
6. Server default placement rules
7. Built-in default conversion and placement rules

4.7.3 Caveats and Restrictions for Specifying Placement

- The place specification cannot be used without the select specification. In other words, you can only specify placement when you have specified chunks.
- A select specification cannot be used with a nodes specification.
- A select specification cannot be used with old-style resource requests such as -lncpus, -lmem, -lvmem, -larch, -lhost.
- When using *place=group=<resource>*, the resource must be a string or string array.
- Do not mix old and new syntax when requesting placement. See section 4.8, "Backward Compatibility", on page 72 for a description of old syntax.
- If your job requests exclusive placement, and it is in a reservation, the reservation must also request exclusive placement via `-l place=excl`.

4.7.4 Examples of Specifying Placement

Unless otherwise specified, the vnodes allocated to the job will be allocated as shared or exclusive based on the setting of the vnode's sharing attribute. Each of the following shows how you would use -l select= and -l place=.

1. A job that will fit in a single host but not in any of the vnodes, packed into the fewest vnodes:

   ```
   -l select=1:ncpus=10:mem=20gb
   -l place=pack
   ```

   In earlier versions, this would have been:

   ```
   -lncpus=10,mem=20gb
   ```

2. Request four chunks, each with 1 CPU and 4GB of memory taken from anywhere.

   ```
   -l select=4:ncpus=1:mem=4GB
   -l place=free
   ```

3. Allocate 4 chunks, each with 1 CPU and 2GB of memory from between

one and four vnodes which have an arch of "linux".

```
-l select=4:ncpus=1:mem=2GB:arch=linux -l place=free
```

4. Allocate four chunks on 1 to 4 vnodes where each vnode must have 1 CPU, 3GB of memory and 1 node-locked dyna license available for each chunk.

```
-l select=4:dyna=1:ncpus=1:mem=3GB -l place=free
```

5. Allocate four chunks on 1 to 4 vnodes, and 4 floating dyna licenses. This assumes "dyna" is specified as a server dynamic resource.

```
-l dyna=4 -l select=4:ncpus=1:mem=3GB -l place=free
```

6. This selects exactly 4 vnodes where the arch is linux, and each vnode will be on a separate host. Each vnode will have 1 CPU and 2GB of memory allocated to the job.

```
-lselect=4:mem=2GB:ncpus=1:arch=linux -lplace=scatter
```

7. This will allocate 3 chunks, each with 1 CPU and 10GB of memory. This will also reserve 100mb of scratch space if scratch is to be accounted . Scratch is assumed to be on a file system common to all hosts. The value of "place" depends on the default which is "place=free".

```
-l scratch=100mb -l select=3:ncpus=1:mem=10GB
```

8. This will allocate 2 CPUs and 50GB of memory on a host named zooland. The value of "place" depends on the default which defaults to "place=free":

```
-l select=1:ncpus=2:mem=50gb:host=zooland
```

9. This will allocate 1 CPU and 6GB of memory and one host-locked swlicense from each of two hosts:

```
-l select=2:ncpus=1:mem=6gb:swlicense=1
-lplace=scatter
```

10. Request free placement of 10 CPUs across hosts:

```
-l select=10:ncpus=1
-l place=free
```

11. Here is an odd-sized job that will fit on a single HPE system, but not on any one node-board. We request an odd number of CPUs that are not shared, so they must be "rounded up":

```
-l select=1:ncpus=3:mem=6gb
-l place=pack:excl
```

12. Here is an odd-sized job that will fit on a single HPE system, but not on any one node-board. We are asking for small number of CPUs but a large amount of memory:

```
-l select=1:ncpus=1:mem=25gb
-l place=pack:excl
```

13. Here is a job that may be run across multiple HPE systems, packed into the fewest vnodes:

```
-l select=2:ncpus=10:mem=12gb
-l place=free
```

14. Submit a job that must be run across multiple HPE systems, packed into the fewest vnodes:

```
-l select=2:ncpus=10:mem=12gb
-l place=scatter
```

15. Request free placement across nodeboards within a single host:

```
-l select=1:ncpus=10:mem=10gb
```

```
-l place=group=host
```

16. Request free placement across vnodes on multiple HPE systems:

```
-l select=10:ncpus=1:mem=1gb
-l place=free
```

17. Here is a small job that uses a shared cpuset:

```
-l select=1:ncpus=1:mem=512kb
-l place=pack:shared
```

18. Request a special resource available on a limited set of nodeboards, such as a graphics card:

```
-l select= 1:ncpus=2:mem=2gb:graphics=True + 1:ncpus=20:mem=20gb:graphics=False
-l place=pack:excl
```

19. Align SMP jobs on c-brick boundaries:

```
-l select=1:ncpus=4:mem=6gb
-l place=pack:group=cbrick
```

20. Align a large job within one router, if it fits within a router:

```
-l select=1:ncpus=100:mem=200gb
-l place=pack:group=router
```

21. Fit large jobs that do not fit within a single router into as few available routers as possible. Here, RES is the resource used for node grouping:

```
-l select=1:ncpus=300:mem=300gb
-l place=pack:group=<RES>
```

22. To submit an MPI job, specify one chunk per MPI task. For a 10-way MPI job with 2gb of memory per MPI task:

```
-l select=10:ncpus=1:mem=2gb
```

23. To submit a non-MPI job (including a 1-CPU job or an OpenMP or shared memory) job, use a single chunk. For a 2-CPU job requiring 10gb of memory:

```
-l  select=1:ncpus=2:mem=10gb
```

4.8 Backward Compatibility

4.8.1 Old-style Resource Specifications

Old versions of PBS allowed job submitters to ask for resources outside of a select statement, using "`-lre-source=value`", where those resources must now be requested in chunks, inside a select statement. This old style of resource request was called a "resource specification". Resource specification syntax is **deprecated**.

For backward compatibility, any resource specification is converted to select and place statements, and any defaults are applied.

4.8.2 Old-style Node Specifications

In early versions of PBS, job submitters used "`-l nodes=...`" in what was called a "node specification" to specify where the job should run. The syntax for a "node specification" is **deprecated**.

For backward compatibility, a legal node specification or resource specification is converted into select and place directives; we show how in following sections.

4.8.3 Conversion of Old Style to New

4.8.3.1 Conversion of Resource Specifications

If your job has an old-style resource specification, PBS creates a select specification requesting 1 chunk containing the resources specified by the job and server and/or queue default resources. Resource specification format:

-l<resource>=<value>[:<resource>=<value> ...]

The resource specification is converted to:

-lselect=1[:<*resource*>=<*value*> ...]

-lplace=pack

with one instance of *resource=value* for each of the following vnode-level resources in the resource request:

built-in resources: ncpus | mem | vmem | arch | host

site-defined vnode-level resources

For example, a job submitted with

qsub -l ncpus=4:mem=123mb:arch=linux

gets the following select statement:

select=1:ncpus=4:mem=123mb:arch=linux

4.8.3.2 Conversion of Node Specifications

If your job requests a node specification, PBS creates a select and place specification, according to the following rules.

Old node specification format:

-lnodes=[N:<*spec list*> | <*spec list*>]

[[+N:<*spec list*> | +<*spec list*>] ...]

[#<s*uffix*> ...][-lncpus=Z]

where:

spec list has syntax: <*spec*>[:<*spec*> ...]

spec is any of: hostname | property | ncpus=X | cpp=X | ppn=P

suffix is any of: property | excl | shared

N and P are positive integers

X and Z are non-negative integers

The node specification is converted into select and place statements as follows:

Each *spec list* is converted into one chunk, so that N:<*spec list*> is converted into N chunks.

If *spec* is hostname :

The chunk will include *host=hostname*

If *spec* matches any vnode's resources_available.<hostname> value:

The chunk will include *host=hostname*

If *spec* is property :

The chunk will include <*property*>=*true*

Property must be a site-defined vnode-level boolean resource.

If *spec* is ncpus=X or cpp=X :

The chunk will include ncpus=X

If no *spec* is ncpus=X and no spec is cpp=X :

The chunk will include ncpus=P

If *spec* is ppn=P :

The chunk will include mpiprocs=P

If the *nodespec* is

```
-lnodes=N:ppn=P
```

It is converted to

```
-lselect=N:ncpus=P:mpiprocs=P
```

Example:

```
-lnodes=4:ppn=2
```

is converted into

```
-lselect=4:ncpus=2:mpiprocs=2
```

If -lncpus=Z is specified and no spec contains ncpus=X and no spec is cpp=X :

Every chunk will include ncpus=W, where W is Z divided by the total number of chunks. (Note: W must be an integer; Z must be evenly divisible by the number of chunks.)

If property is a suffix :

All chunks will include property=true

If excl is a suffix :

The placement directive will be -lplace=scatter:excl

If shared is a suffix :

The placement directive will be -lplace=scatter:shared

If neither excl nor shared is a suffix :

The placement directive will be -lplace=scatter

Example:

```
-lnodes=3:green:ncpus=2:ppn=2+2:red
```

is converted to:

```
-l select=3:green=true:ncpus=4:mpiprocs=2+ 2:red=true:ncpus=1
-l place=scatter
```

4.8.3.3 Examples of Converting Old Syntax to New

1. Request CPUs and memory on a single host using old syntax:
   ```
   -l ncpus=5,mem=10gb
   ```

is converted into the equivalent:

```
-l select=1:ncpus=5:mem=10gb
-l place=pack
```

2. Request CPUs and memory on a named host along with custom resources including a floating license using old syntax:

```
-l ncpus=1,mem=5mb,host=sunny,opti=1,arch=arch1
```

is converted to the equivalent:

```
-l select=1:ncpus=1:mem=5gb:host=sunny:arch=arch1
-l place=pack
-l opti=1
```

3. Request one host with a certain property using old syntax:

```
-lnodes=1:property
```

is converted to the equivalent:

```
-l select=1:ncpus=1:property=True
-l place=scatter
```

4. Request 2 CPUs on each of four hosts with a given property using old syntax:

```
-lnodes=4:property:ncpus=2
```

is converted to the equivalent:

```
-l select=4: ncpus=2:property=True -l place=scatter
```

5. Request 1 CPU on each of 14 hosts asking for certain software, licenses and a job limit amount of memory using old syntax:

```
-lnodes=14:mpi-fluent:ncpus=1 -lfluent=1,fluent-all=1, fluent-par=13
-l mem=280mb
```

is converted to the equivalent:

```
-l select=14:ncpus=1:mem=20mb:mpi_fluent=True
-l place=scatter
-l fluent=1,fluent-all=1,fluent-par=13
```

6. Requesting licenses using old syntax:

```
-lnodes=3:dyna-mpi-Linux:ncpus=2 -ldyna=6,mem=100mb, software=dyna
```

is converted to the equivalent:

```
-l select=3:ncpus=2:mem=33mb: dyna-mpi-Linux=True
-l place=scatter
-l software=dyna
-l dyna=6
```

7. Requesting licenses using old syntax:

```
 -l ncpus=2,app_lic=6,mem=200mb -l software=app
```

is converted to the equivalent:

```
-l select=1:ncpus=2:mem=200mb
-l place=pack
-l software=app
-l app_lic=6
```

8. Additional example using old syntax:

   ```
   -lnodes=1:fserver+15:noserver
   ```

   is converted to the equivalent:

   ```
   -l select=1:ncpus=1:fserver=True + 15:ncpus=1:noserver=True
   -l place=scatter
   ```

   but could also be more easily specified with something like:

   ```
   -l select=1:ncpus=1:fserver=True + 15:ncpus=1:fserver=False
   -l place=scatter
   ```

9. Allocate 4 vnodes, each with 6 CPUs with 3 MPI processes per vnode, with each vnode on a separate host. The memory allocated would be one-fourth of the memory specified by the queue or server default if one existed. This results in a different placement of the job from version 5.4:

   ```
   -lnodes=4:ppn=3:ncpus=2
   ```

   is converted to:

   ```
   -l select=4:ncpus=6:mpiprocs=3 -l place=scatter
   ```

10. Allocate 4 vnodes, from 4 separate hosts, with the property blue. The amount of memory allocated from each vnode is 2560MB (= 10GB / 4) rather than 10GB from each vnode.

    ```
    -lnodes=4:blue:ncpus=2 -l mem=10GB
    ```

    is converted to:

    ```
    -l select=4:blue=True:ncpus=2:mem=2560mb -lplace=scatter
    ```

4.8.4 Caveats for Using Old Syntax

4.8.4.1 Changes in Behavior

Most jobs submitted with "`-lnodes`" will continue to work as expected. These jobs will be automatically converted to the new syntax. However, job tasks may execute in an unexpected order, because vnodes may be assigned in a different order. Jobs submitted with old syntax that ran successfully on versions of PBS Professional prior to 8.0 can fail because a limit that was per-chunk is now job-wide.

Example 4-16: A job submitted using `-lnodes=X -lmem=M` that fails because the mem limit is now job-wide. If the following conditions are true:

- PBS Professional 9.0 or later using standard MPICH
- The job is submitted with `qsub -lnodes=5 -lmem=10GB`
- The master process of this job tries to use more than 2GB

The job is killed, where in <= 7.0 the master process could use 10GB before being killed. 10GB is now a job-wide limit, divided up into a 2GB limit per chunk.

4.8.4.2 Do Not Mix Old and New Styles

Do not mix old style resource or node specifications ("`-l<resource>=<value>`" or "`-lnodes`") with select and place statements ("`-lselect=`" or "`-lplace=`"). Do not use both in the command line. Do not use both in the job script. Do not use one in a job script and the other on the command line. This will result in an error.

4.8.4.3 Resource Request Conversion Dependent on Where Resources are Defined

A job's resource request is converted from old-style to new according to various rules, one of which is that the conversion is dependent upon where resources are defined. For example: The boolean resource "Red" is defined on the server, and the boolean resource "Blue" is defined at the host level. A job requests "`qsub -l Blue=true`". This looks like an old-style resource request, and PBS checks to see where Blue is defined. Since Blue is defined at the host level, the request is converted into "`-l select=1:Blue=true`". However, if a job requests "`qsub -l Red=true`", while this looks like an old-style resource request, PBS does not convert it to a chunk request because Red is defined at the server.

4.8.4.4 Properties are Deprecated

The syntax for requesting properties is **deprecated**. Your administrator has replaced properties with Booleans.

4.8.4.5 Replace cpp with ncpus

Specifying "cpp" is part of the old syntax, and should be replaced with "ncpus".

4.8.4.6 Environment Variables Set During Conversion

When a node specification is converted into a select statement, the job has the environment variables NCPUS and OMP_NUM_THREADS set to the old value of ncpus in the first piece of the old node specification. This may produce incompatibilities with prior versions when a complex node specification using different values of ncpus and ppn in different pieces is converted.

4.8.4.7 Old -l nodes Syntax Incompatible with Cgroups

The cgroups hook does not transform old "-lnodes" syntax into the new select and place directives. If you need to use the old syntax on hosts managed by the cgroups hook, your site can use a queuejob hook to do that for you, or you can explicitly specify mem, vmem, and cgswap for jobs.

5 Multiprocessor Jobs

5.1 Submitting Multiprocessor Jobs

Before you read this chapter, please read Chapter 4, "Allocating Resources & Placing Jobs", on page 51.

5.1.1 Assigning the Chunks You Want

PBS assigns chunks to job processes in the order in which the chunks appear in the select statement. PBS takes the first chunk from the primary execution host; this is where the top task of the job runs.

Example 5-1: You want three chunks, where the first has two CPUs and 20 GB of memory, the second has four CPUs and 100 GB of memory, and the third has one CPU and five GB of memory:

```
-lselect=1:ncpus=2:mem=20gb+ncpus=4:mem=100gb+mem=5gb
```

5.1.1.1 Specifying Primary Execution Host

The job's primary execution host is the host that supplies the vnode to satisfy the first chunk requested by the job.

5.1.1.2 Request Most Specific Chunks First

Chunk requests are interpreted from left to right. The more specific the chunk, the earlier it should be in the order. For example, if you require a specific host for chunk A, but chunk B is not host-specific, request Chunk A first.

5.1.2 The Job Node File

For each job, PBS creates a job-specific "host file" or "node file", which is a text file containing the name(s) of the host(s) containing the vnode(s) allocated to that job. The file is set on all execution hosts assigned to the job.

5.1.2.1 Node File Format and Contents

The node file contains a list of host names, one per line. The name of the host is the value in resources_available.host of the allocated vnode(s). The order in which hosts appear in the PBS node file is the order in which chunks are specified in the selection directive.

The node file contains one line per MPI process with the name of the host on which that process should execute. The number of MPI processes for a job, and the contents of the node file, are controlled by the value of the resource mpiprocs. mpiprocs is the number of MPI processes per chunk, and defaults to *1* where the chunk contains CPUs, *0* otherwise.

For each chunk requesting mpiprocs=*M*, the name of the host from which that chunk is allocated is written in the node file *M* times. Therefore the number of lines in the node file is the sum of requested mpiprocs for all chunks requested by the job.

Example 5-2: Two MPI processes run on HostA and one MPI process runs on HostB. The node file looks like this:

```
HostA
HostA
HostB
```

5.1.2.2 Name and Location of Node File

The file is created each execution host assigned to the job, in `PBS_HOME/aux/JOB_ID`, where *JOB_ID* is the job identifier for that job.

The full path and name for the node file is set in the job's environment, in the environment variable PBS_NODEFILE.

5.1.2.3 Node File for Old-style Requests

For jobs which request resources using the old *-lnodes=nodespec* format, the host for each vnode allocated to the job is listed *N* times, where *N* is the number of MPI ranks on the vnode. The number of MPI ranks is specified via the ppn resource.

Example 5-3: Request four vnodes, each with two MPI processes, where each process has three threads, and each thread has a CPU:

```
qsub -lnodes=4:ncpus=3:ppn=2
```

This results in each of the four hosts being written twice, in the order in which the vnodes are assigned to the job.

5.1.2.4 Using and Modifying the Node File

You can use $PBS_NODEFILE in your job script.

You can modify the node file. You can remove entries or sort the entries.

5.1.2.5 Node File Caveats

Do not add entries for new hosts; PBS may terminate processes on those hosts because PBS does not expect the processes to be running there. Adding entries on the same host may cause the job to be terminated because it is using more CPUs than it requested.

5.1.2.6 Viewing Execution Hosts

You can see which host is the primary execution host: the primary execution host is the first host listed in the job's node file.

5.1.3 Specifying Number of MPI Processes Per Chunk

How you request chunks matters. First, the number of MPI processes per chunk defaults to *1* for chunks with CPUs, and *0* for chunks without CPUs, unless you specify this value using the mpiprocs resource. Second, you can specify whether MPI processes share CPUs. For example, requesting one chunk with four CPUs and four MPI processes is not the same as requesting four chunks each with one CPU and one MPI process. In the first case, all four MPI processes are sharing all four CPUs. In the second case, each process gets its own CPU.

You request the number of MPI processes you want for each chunk using the mpiprocs resource. For example, to request two MPI processes for each of four chunks, where each chunk has two CPUs:

```
-lselect=4:ncpus=2:mpiprocs=2
```

If you don't explicitly request a value for the mpiprocs resource, it defaults to *1* for each chunk requesting CPUs, and *0* for chunks not requesting CPUs.

Example 5-4: To request one chunk with two MPI processes and one chunk with one MPI process, where both chunks have two CPUs:

```
-lselect=ncpus=2:mpiprocs=2+ncpus=2
```

Example 5-5: A request for three vnodes, each with one MPI process:

```
qsub -l select=3:ncpus=2
```

This results in the following node file:

```
<hostname for 1st vnode>
<hostname for 2nd vnode>
<hostname for 3rd vnode>
```

Example 5-6: If you want to run two MPI processes on each of three hosts and have the MPI processes share a single processor on each host, request the following:

```
-lselect=3:ncpus=1:mpiprocs=2
```

The node file then contains the following list:

```
hostname for VnodeA
hostname for VnodeA
hostname for VnodeB
hostname for VnodeB
hostname for VnodeC
hostname for VnodeC
```

Example 5-7: If you want three chunks, each with two CPUs and running two MPI processes, use:

```
-l select=3:ncpus=2:mpiprocs=2...
```

The node file then contains the following list:

```
hostname for VnodeA
hostname for VnodeA
hostname for VnodeB
hostname for VnodeB
hostname for VnodeC
hostname for VnodeC
```

Notice that the node file is the same as the previous example, even though the number of CPUs used is different.

Example 5-8: If you want four MPI processes, where each process has its own CPU:

```
-lselect=4:ncpus=1
```

See "Resources Built Into PBS" on page 265 of the PBS Professional Reference Guide for a definitions of the mpiprocs resource.

5.1.3.1 Chunks With No MPI Processes

If you request a chunk that has no MPI processes, PBS may take that chunk from a vnode which has already supplied another chunk. You request a chunk that has no MPI processes using either of the following:

```
-lselect=1:ncpus=0
-lselect=1:ncpus=2:mpiprocs=0
```

5.1.4 Caveats and Advice for Multiprocessor Jobs

5.1.4.1 Requesting Uniform Processors

Some MPI jobs require the work on all vnodes to be at the same stage before moving to the next stage. For these applications, the work can proceed only at the pace of the slowest vnode, because faster vnodes must wait while it catches up. In this case, you may find it useful to ensure that the job's vnodes are homogeneous.

If there is a resource that identifies the architecture, type, or speed of the vnodes, you can use it to ensure that all chunks are taken from vnodes with the same value. You can either request a specific value for this resource for all chunks, or you can group vnodes according to the value of the resource. See section 4.7.1.3, “Grouping on a Resource”, on page 69.

Example 5-9: The resource that identifies the speed is named *speed*, and your job requests 16 chunks, each with two CPUs, two MPI processes, all with speed equal to *fast*:

```
-lselect=16:ncpus=2:mpiprocs=2:speed=fast
```

Example 5-10: Request 16 chunks where each chunk has two CPUs, using grouping to ensure that all chunks share the same speed. The resource that identifies the speed is named *speed*:

```
-lselect=16:ncpus=2:mpiprocs=2:place=group=speed
```

5.1.4.2 Requesting Storage on NFS Server

One of the vnodes in your complex may act as an NFS server to the rest of the vnodes, so that all vnodes have access to the storage on the NFS server.

Example 5-11: The scratch resource is shared among all the vnodes in the complex, and is requested from a central location, called the "*nfs_server*" vnode. To request two vnodes, each with two CPUs to do calculations, and one vnode with 10gb of memory and no MPI processes:

```
-l select=2:ncpus=2+1:host=nfs_server:scratch=10gb:ncpus=0
```

With this request, your job has one MPI process on each chunk containing CPUs, and no MPI processes on the memory-only chunk. The job shows up as having a chunk on the "nfs_server" host.

5.1.5 File Staging for Multiprocessor Jobs

PBS stages files to and from the primary execution host only.

5.1.6 Prologue and Epilogue

The prologue is run as root on the primary host, with the current working directory set to `PBS_HOME/mom_priv`, and with PBS_JOBDIR and TMPDIR set in its environment.

PBS runs the epilogue as root on the primary host. The epilogue is executed with its current working directory set to the job's staging and execution directory, and with PBS_JOBDIR and TMPDIR set in its environment.

5.1.7 MPI Environment Variables

NCPUS

PBS sets the NCPUS environment variable in the job's environment on the primary execution host. PBS sets NCPUS to the value of ncpus requested for the first chunk.

OMP_NUM_THREADS

PBS sets the OMP_NUM_THREADS environment variable in the job's environment on the primary execution host. PBS sets this variable to the value of ompthreads requested for the first chunk, which defaults to the value of ncpus requested for the first chunk.

5.1.8 Examples of Multiprocessor Jobs

Example 5-12: For a 10-way MPI job with 2gb of memory per MPI task:

```
qsub -l select=10:ncpus=1:mem=2gb
```

Example 5-13: If you have a cluster of small systems with for example two CPUs each, and you wish to submit an MPI job that will run on four separate hosts:

```
qsub -l select=4:ncpus=1 -l place=scatter
```

In this example, the node file contains one entry for each of the hosts allocated to the job, which is four entries.

The variables NCPUS and OMP_NUM_THREADS are set to one.

Example 5-14: If you do not care where the four MPI processes are run:

```
qsub -l select=4:ncpus=1 -l place=free
```

Here, the job runs on two, three, or four hosts depending on what is available.

For this example, the node file contains four entries. These are either four separate hosts, or three hosts, one of which is repeated once, or two hosts, etc.

NCPUS and OMP_NUM_THREADS are set to *1*, the number of CPUs allocated from the first chunk.

5.1.9 Submitting SMP Jobs

To submit an SMP job, simply request a single chunk containing all of the required CPUs and memory, and if necessary, specify the hostname. For example:

```
qsub -l select=ncpus=8:mem=20gb:host=host1
```

When the job is run, the node file will contain one entry, the name of the selected execution host.

The job will have two environment variables, NCPUS and OMP_NUM_THREADS, set to the number of CPUs allocated.

5.2 Using MPI with PBS

5.2.1 Using an Integrated MPI

Many MPIs are integrated with PBS. PBS provides tools to integrate most of them; a few MPIs supply the integration. When a job is run under an integrated MPI, PBS can track resource usage, signal job processes, and perform accounting for all processes of the job.

When a job is run under an MPI that is not integrated with PBS, PBS is limited to managing the job only on the primary vnode, so resource tracking, job signaling, and accounting happen only for the processes on the primary vnode.

The instructions that follow are for integrated MPIs. Check with your administrator to find out which MPIs are integrated at your site. If an MPI is not integrated with PBS, you use it as you would outside of PBS.

Some of the integrated MPIs have slightly different command lines. See the instructions for each MPI.

The following table lists the supported MPIs and gives links to instructions for using each MPI:

Table 5-1: List of Supported MPIs

MPI Name	Versions	Instructions for Use
HP MPI	1.08.03 2.0.0	See section 5.2.4, “HP MPI with PBS”, on page 86
Intel MPI	2.0.022 3 4	See section 5.2.7, “Intel MPI 2.0.022, 3, and 4 with PBS”, on page 87
Intel MPI	4.0.3 on Linux	See section 5.2.5, “Intel MPI 4.0.3 On Linux with PBS”, on page 86
Intel MPI	4.0.3 on Windows	See section 5.2.6, “Intel MPI 4.0.3 On Windows with PBS”, on page 87
MPICH-P4 **Deprecated**.	1.2.5 1.2.6 1.2.7	See section 5.2.8, “MPICH-P4 with PBS”, on page 90
MPICH-GM **Deprecated**.		See section 5.2.9, “MPICH-GM with PBS”, on page 91
MPICH-MX **Deprecated**.		See section 5.2.10, “MPICH-MX with PBS”, on page 94
MPICH2 **Deprecated**.	1.0.3 1.0.5 1.0.7 On Linux	See section 5.2.11, “MPICH2 with PBS on Linux”, on page 96
MPICH2	1.4.1p1 on Windows	See section 5.2.12, “MPICH2 1.4.1p1 On Windows with PBS”, on page 99
MVAPICH **Deprecated**.	1.2	See section 5.2.13, “MVAPICH with PBS”, on page 99
MVAPICH2	1.8	See section 5.2.14, “MVAPICH2 with PBS”, on page 100
Open MPI	1.4.x	See section 5.2.15, “Open MPI with PBS”, on page 102
Platform MPI	8.0	See section 5.2.16, “Platform MPI with PBS”, on page 102
HPE MPI	Any	See section 5.2.17, “HPE MPI with PBS”, on page 103

5.2.1.1 Integration Caveats

- Some MPI command lines are slightly different; the differences for each are described.

5.2.1.2 Integrating an MPI on the Fly

The PBS administrator can perform the steps to integrate the supported MPIs. For non-integrated MPIs, you can integrate them on the fly. You integrate Intel MPI 4.0.3 using environment variables; see section 5.2.5, "Intel MPI 4.0.3 On Linux with PBS", on page 86. For the rest, you integrate them using the `pbs_tmrsh` command.

5.2.1.2.i Integrating an MPI on the Fly using the `pbs_tmrsh` Command

You should not use `pbs_tmrsh` with an integrated MPI or with Intel MPI 4.0.3.

This command emulates `rsh`, but uses the PBS TM interface to talk directly to `pbs_mom` on sister vnodes. The `pbs_tmrsh` command informs the primary and sister MoMs about job processes on sister vnodes. When the job uses `pbs_tmrsh`, PBS can track resource usage for all job processes.

You use `pbs_tmrsh` as your `rsh` or `ssh` command. To use `pbs_tmrsh`, set the appropriate environment variable to *pbs_tmrsh*. For example, to integrate MPICH, set the P4_RSHCOMMAND environment variable to *pbs_tmrsh*, and to integrate HP MPI, set MPI_REMSH to *pbs_tmrsh*.

The following figure illustrates how the `pbs_tmrsh` command can be used to integrate an MPI on the fly:

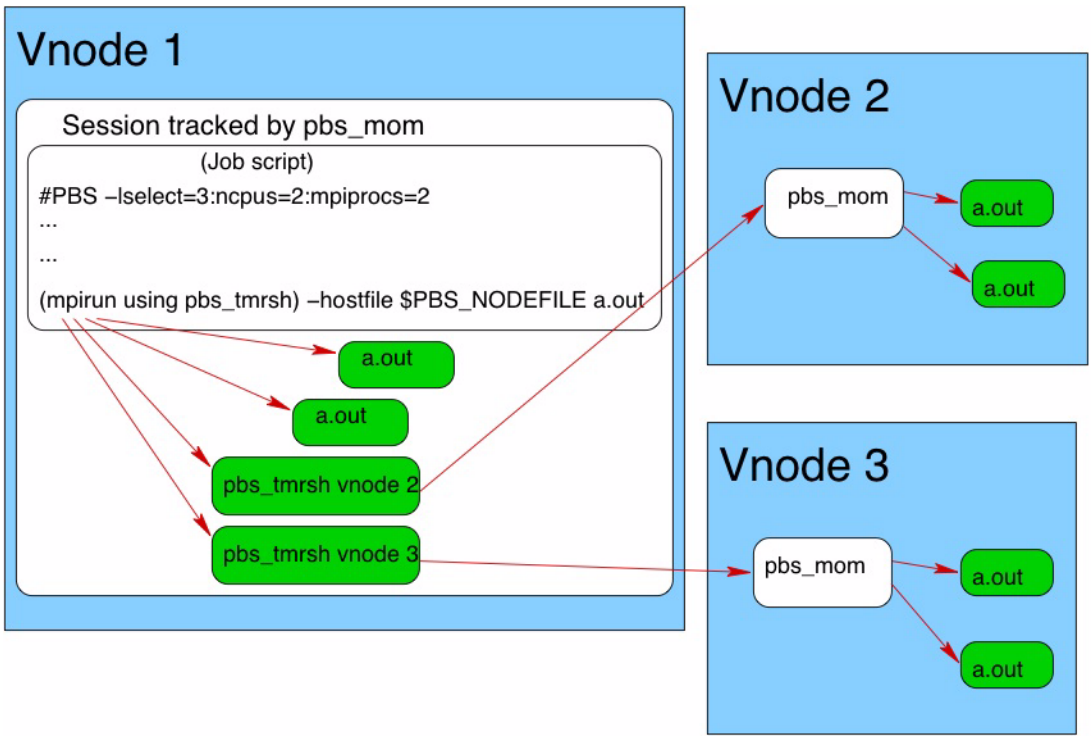

Figure 5-1:PBS knows about processes on vnodes 2 and 3, because `pbs_tmrsh` talks directly to `pbs_mom`, and `pbs_mom` starts the processes on vnodes 2 and 3

5.2.1.2.ii Caveats for the `pbs_tmrsh` Command

- This command cannot be used outside of a PBS job; if used outside a PBS job, this command will fail.
- The `pbs_tmrsh` command does not perform exactly like `rsh`. For example, you cannot pipe output from `pbs_tmrsh`; this will fail.

5.2.2 Prerequisites to Using MPI with PBS

The MPI that you intend to use with PBS must be working before you try to use it with PBS. You must be able to run an MPI job outside of PBS.

5.2.3 Caveats for Using MPIs

Some applications write scratch files to a temporary location. PBS makes a temporary directory available for this, and puts the path in the TMPDIR environment variable. The location of the temporary directory is host-dependent. If you are using an MPI other than Open MPI, and your application needs scratch space, the temporary directory for the job should be consistent across execution hosts. Your PBS administrator can specify a root for the temporary directory on each host using the $tmpdir MoM parameter. In this case, the TMPDIR environment variable is set to the full path of the resulting temporary directory. Do not attempt to set TMPDIR.

5.2.4 HP MPI with PBS

HP MPI can be integrated with PBS on Linux so that PBS can track resource usage, signal processes, and perform accounting, for all job processes. Your PBS administrator can integrate HP MPI with PBS.

5.2.4.1 Setting up Your Environment for HP MPI

In order to override the default `rsh`, set PBS_RSHCOMMAND in your job script:

```
export PBS_RSHCOMMAND=<rsh choice>
```

5.2.4.2 Using HP MPI with PBS

You can run jobs under PBS using HP MPI without making any changes to your MPI command line.

5.2.4.3 Options

When running a PBS HP MPI job, you can use the same arguments to the `mpirun` command as you would outside of PBS. The following options are treated differently under PBS:

-h <host>
: Ignored

-l <user>
: Ignored

-np <number>
: Modified to fit the available resources

5.2.4.4 Caveats for HP MPI with PBS

Under the integrated HP MPI, the job's working directory is changed to your home directory.

5.2.5 Intel MPI 4.0.3 On Linux with PBS

If your PBS administrator has integrated Intel MPI 4.0.3 on Linux with PBS, you can use its `mpirun` exactly the same way inside and outside of a PBS job.

The default process manager for Intel MPI 4.0.3 on Linux is Hydra.

5.2.6 Intel MPI 4.0.3 On Windows with PBS

On Windows PBS supplies a wrapper script for Intel MPI called pbs_intelmpi_mpirun.bat, located in $PBS_EXEC\bin. You call this script instead of Intel mpirun. All options are passed through the script to mpirun.

5.2.6.1 Integrating Intel MPI 4.0.3 on the Fly

If you are using Intel MPI 4.0.3 but it has not been integrated with PBS, you can integrate it on the fly by setting environment variables:

1. Specify rsh:
   I_MPI_HYDRA_BOOTSTRAP=rsh
2. Specify pbs_tmrsh.
   a. If you are running your job entirely on hosts which have PBS_EXEC/bin in the default PATH, set this:
      I_MPI_HYDRA_BOOTSTRAP_EXEC=pbs_tmrsh
   b. If you are running your job entirely on hosts which do not have PBS_EXEC/bin in the default PATH, include the full path in the environment variable. For example:
      I_MPI_HYDRA_BOOTSTRAP_EXEC=/opt/pbs/bin/pbs_tmrsh

5.2.7 Intel MPI 2.0.022, 3, and 4 with PBS

PBS provides an interface to Intel MPI mpirun for these versions. If executed inside a PBS job, this allows PBS to track all Intel MPI processes so that PBS can perform accounting and have complete job control. If executed outside of a PBS job, it behaves exactly as if standard Intel MPI mpirun was used.

5.2.7.1 Using Intel MPI 2.0.022, 3, or 4 Integrated with PBS

You use the same mpirun command as you would use outside of PBS.

When submitting PBS jobs that invoke the PBS-supplied interface to mpirun for Intel MPI, be sure to explicitly specify the actual number of ranks or MPI tasks in the qsub select specification. Otherwise, jobs will fail to run with "too few entries in the machinefile".

For an example of this problem, specification of the following:

```
#PBS -l select=1:ncpus=1:host=hostA+1:ncpus=2:host=hostB
mpirun -np 3 /tmp/mytask
```

results in the following node file:

```
hostA
hostB
```

which conflicts with the "-np 3" specification in mpirun since only two MPD daemons are started.

The correct way is to specify either of the following:

```
#PBS -l select=1:ncpus=1:host=hostA+2:ncpus=1:host=hostB
#PBS -l select=1:ncpus=1:host=hostA+1:ncpus=2:host=hostB:mpiprocs=2
```

which causes the node file to contain:

```
hostA
hostB
hostB
```

and is consistent with "mpirun -np 3".

5.2.7.2 Options to Integrated Intel MPI 2.0.022, 3, or 4

If executed inside a PBS job script, all of the options to the PBS interface are the same as for Intel MPI's `mpirun` except for the following:

-host, -ghost

For specifying the execution host to run on. Ignored.

-machinefile <file>

The file argument contents are ignored and replaced by the contents of $PBS_NODEFILE.

mpdboot option --totalnum=*

Ignored and replaced by the number of unique entries in $PBS_NODEFILE.

mpdboot option --file=*

Ignored and replaced by the name of $PBS_NODEFILE. The argument to this option is replaced by $PBS_NODEFILE.

Argument to `mpdboot` option `-f <mpd_hosts_file>` replaced by $PBS_NODEFILE.

-s

If the PBS interface to Intel MPI's `mpirun` is called inside a PBS job, Intel MPI's `mpirun -s` argument to `mpdboot` is not supported as this closely matches the `mpirun` option "`-s <spec>`". You can simply run a separate `mpdboot -s` before calling `mpirun`. A warning message is issued by the PBS interface upon encountering a `-s` option describing the supported form.

-np

If you do not specify a `-np` option, then no default value is provided by the PBS interface. It is up to the standard `mpirun` to decide what the reasonable default value should be, which is usually *1*. The maximum number of ranks that can be launched is the number of entries in $PBS_NODEFILE.

5.2.7.3 MPD Startup and Shutdown

Intel MPI's `mpirun` takes care of starting and stopping the MPD daemons. The PBS interface to Intel MPI's `mpirun` always passes the arguments `-totalnum=<number of mpds to start>` and `-file=<mpd_hosts_file>` to the actual `mpirun`, taking its input from unique entries in $PBS_NODEFILE.

5.2.7.4 Examples

Example 5-15: Run a single-executable Intel MPI job with six processes spread out across the PBS-allocated hosts listed in $PBS_NODEFILE:

Node file:

```
pbs-host1
pbs-host1
pbs-host2
pbs-host2
pbs-host3
pbs-host3
```

Job script:

```
# mpirun takes care of starting the MPD
# daemons on unique hosts listed in
# $PBS_NODEFILE, and also runs the 6 processes
# on the 6 hosts listed in
# $PBS_NODEFILE; mpirun takes care of
# shutting down MPDs.
mpirun /path/myprog.x 1200
```

Run job script:

```
qsub -l select=3:ncpus=2:mpiprocs=2 job.script
<job ID>
```

Example 5-16: Run an Intel MPI job with multiple executables on multiple hosts using $PBS_NODEFILE and `mpiexec` arguments to `mpirun`:

$PBS_NODEFILE:

```
hostA
hostA
hostB
hostB
hostC
hostC
```

Job script:

```
# mpirun runs MPD daemons on hosts listed in $PBS_NODEFILE
# mpirun runs 2 instances of mpitest1
# on hostA; 2 instances of mpitest2 on
# hostB; 2 instances of mpitest3 on hostC.
# mpirun takes care of shutting down the
# MPDs at the end of MPI job run.
mpirun -np 2 /tmp/mpitest1 : -np 2 /tmp/mpitest2 : -np 2 /tmp/mpitest3
```

Run job script:

```
qsub -l select=3:ncpus=2:mpiprocs=2 job.script
 <job ID>
```

Example 5-17: Run an Intel MPI job with multiple executables on multiple hosts via the `-configfile` option and $PBS_NODEFILE:

$PBS_NODEFILE:

```
hostA
hostA
hostB
hostB
hostC
hostC
```

Job script:

```
echo "-np 2 /tmp/mpitest1" >> my_config_file
echo "-np 2 /tmp/mpitest2" >> my_config_file
echo "-np 2 /tmp/mpitest3" >> my_config_file

# mpirun takes care of starting the MPD daemons
# config file says run 2 instances of mpitest1
# on hostA; 2 instances of mpitest2 on
# hostB; 2 instances of mpitest3 on hostC.
# mpirun takes care of shutting down the MPD daemons.
mpirun -configfile my_config_file

# cleanup
rm -f my_config_file
```

Run job script:

```
qsub -l select=3:ncpus=2:mpiprocs=2 job.script
<job ID>
```

5.2.7.5 Restrictions

The maximum number of ranks that can be launched under integrated Intel MPI is the number of entries in $PBS_NODEFILE.

5.2.8 MPICH-P4 with PBS

The wrapper is **deprecated**. MPICH-P4 can be integrated with PBS on Linux so that PBS can track resource usage, signal processes, and perform accounting, for all job processes. Your PBS administrator can integrate MPICH-P4 with PBS.

5.2.8.1 Options for MPICH-P4 with PBS

Under PBS, the syntax and arguments for the MPICH-P4 `mpirun` command on Linux are the same except for one option, which you should not set:

-machinefile <file>

PBS supplies the machinefile. If you try to specify it, PBS prints a warning that it is replacing the machinefile.

5.2.8.2 Example of Using MPICH-P4 with PBS

Example of using `mpirun`:

```
#PBS -l select=arch=linux
#
mpirun a.out
```

5.2.8.3 MPICH Under Windows

Under Windows, you may need to use the -localroot option to MPICH's mpirun command in order to allow the job's processes to run more efficiently, or to get around the error "failed to communicate with the barrier command". Here is an example job script:

```
C:\DOCUME~1\user1>type job.scr
echo begin
type %PBS_NODEFILE%
"\Program Files\MPICH\mpd\bin\mpirun" -localroot -np 2 -machinefile %PBS_NODEFILE%
    \winnt\temp\netpipe -reps 3
echo done
```

You also need to specify "arch=windows" in each chunk specification.

5.2.8.3.i Caveats for MPICH Under Windows

Under Windows, MPICH is not integrated with PBS. Therefore, PBS is limited to tracking and controlling processes and performing accounting only for job processes on the primary vnode.

5.2.9 MPICH-GM with PBS

5.2.9.1 Using MPICH-GM and MPD with PBS

The wrapper is **deprecated**. PBS provides an interface to MPICH-GM's mpirun using MPD. If executed inside a PBS job, this allows for PBS to track all MPICH-GM processes started by the MPD daemons so that PBS can perform accounting and have complete job control. If executed outside of a PBS job, it behaves exactly as if standard mpirun with MPD had been used.

You use the same mpirun command as you would use outside of PBS. If the MPD daemons are not already running, the PBS interface will take care of starting them for you.

5.2.9.1.i Options

Inside a PBS job script, all of the options to the PBS interface are the same as mpirun with MPD except for the following:

-m <file>

The file argument contents are ignored and replaced by the contents of $PBS_NODEFILE.

-np

If not specified, the number of entries found in $PBS_NODEFILE is used. The maximum number of ranks that can be launched is the number of entries in $PBS_NODEFILE

-pg

The use of the -pg option, for having multiple executables on multiple hosts, is allowed but it is up to you to make sure only PBS hosts are specified in the process group file; MPI processes spawned on non-PBS hosts are not guaranteed to be under the control of PBS.

5.2.9.1.ii MPD Startup and Shutdown

The script starts MPD daemons on each of the unique hosts listed in $PBS_NODEFILE, using either the rsh or ssh method based on the value of the environment variable RSHCOMMAND. The default is rsh. The script also takes care of shutting down the MPD daemons at the end of a run.

If the MPD daemons are not running, the PBS interface to mpirun will start GM's MPD daemons as you on the allocated PBS hosts. The MPD daemons may have been started already by the administrator or by you. MPD daemons are not started inside a PBS prologue script since it won't have the path of mpirun that you executed (GM or MX), which would determine the path to the MPD binary.

5.2.9.1.iii Examples

Example 5-18: Run a single-executable MPICH-GM job with 3 processes spread out across the PBS-allocated hosts listed in $PBS_NODEFILE:

$PBS_NODEFILE:

```
pbs-host1
pbs-host2
pbs-host3
```

```
qsub -l select=3:ncpus=1
[MPICH-GM-HOME]/bin/mpirun -np 3 /path/myprog.x 1200
^D
<job ID>
```

If the GM MPD daemons are not running, the PBS interface to mpirun will start them as you on the allocated PBS hosts. The daemons may have been previously started by the administrator or by you.

Example 5-19: Run an MPICH-GM job with multiple executables on multiple hosts listed in the process group file procgrp:

Job script:

```
qsub -l select=2:ncpus=1
echo  "host1 1 user1 /x/y/a.exe arg1 arg2" > procgrp
echo  "host2 1 user1 /x/x/b.exe arg1 arg2" >> procgrp

[MPICH-GM-HOME]/bin/mpirun -pg procgrp /path/mypro.x 1200
rm -f procgrp
^D
<job ID>
```

When the job runs, mpirun gives the warning message:

```
warning: "-pg" is allowed but it is up to user to make sure only PBS hosts are specified; MPI
    processes spawned are not guaranteed to be under PBS-control.
```

The warning is issued because if any of the hosts listed in procgrp are not under the control of PBS, then the processes on those hosts will not be under the control of PBS.

5.2.9.2 Using MPICH-GM and rsh/ssh with PBS

PBS provides an interface to MPICH-GM's mpirun using rsh/ssh. If executed inside a PBS job, this lets PBS track all MPICH-GM processes started via rsh/ssh so that PBS can perform accounting and have complete job control. If executed outside of a PBS job, it behaves exactly as if standard mpirun had been used.

You use the same mpirun command as you would use outside of PBS.

5.2.9.2.i Options

Inside a PBS job script, all of the options to the PBS interface are the same as mpirun except for the following:

-machinefile <file>

The file argument contents are ignored and replaced by the contents of $PBS_NODEFILE.

-np

If not specified, the number of entries found in $PBS_NODEFILE is used. The maximum number of ranks that can be launched is the number of entries in $PBS_NODEFILE.

-pg

The use of the -pg option, for having multiple executables on multiple hosts, is allowed but it is up to you to make sure only PBS hosts are specified in the process group file; MPI processes spawned on non-PBS hosts are not guaranteed to be under the control of PBS.

5.2.9.2.ii Examples

Example 5-20: Run a single-executable MPICH-GM job with 64 processes spread out across the PBS-allocated hosts listed in $PBS_NODEFILE:

$PBS_NODEFILE:

```
pbs-host1
pbs-host2
...
pbs-host64
```

```
qsub -l select=64:ncpus=1 -l place=scatter
mpirun -np 64 /path/myprog.x 1200
^D
<job ID>
```

Example 5-21: Run an MPICH-GM job with multiple executables on multiple hosts listed in the process group file procgrp:

```
qsub -l select=2:ncpus=1
echo  "host1 1 user1 /x/y/a.exe arg1 arg2" > procgrp
echo  "host2 1 user1 /x/x/b.exe arg1 arg2" >> procgrp
mpirun -pg procgrp /path/mypro.x
rm -f procgrp
^D
<job ID>
```

When the job runs, mpirun gives this warning message:

```
warning: "-pg" is allowed but it is up to user to make sure only PBS hosts are specified; MPI
    processes spawned are not guaranteed to be under the control of PBS.
```

The warning is issued because if any of the hosts listed in procgrp are not under the control of PBS, then the processes on those hosts will not be under the control of PBS.

5.2.9.3 Restrictions

The maximum number of ranks that can be launched under integrated MPICH-GM is the number of entries in $PBS_NODEFILE.

5.2.10 MPICH-MX with PBS

5.2.10.1 Using MPICH-MX and MPD with PBS

The wrapper is **deprecated**. PBS provides an interface to MPICH-MX's `mpirun` using MPD. If executed inside a PBS job, this allows for PBS to track all MPICH-MX processes started by the MPD daemons so that PBS can perform accounting and have complete job control. If executed outside of a PBS job, it behaves exactly as if standard MPICH-MX `mpirun` with MPD was used.

You use the same `mpirun` command as you would use outside of PBS. If the MPD daemons are not already running, the PBS interface will take care of starting them for you.

5.2.10.1.i Options

Inside a PBS job script, all of the options to the PBS interface are the same as `mpirun` with MPD except for the following:

-m <file>

The `file` argument contents are ignored and replaced by the contents of $PBS_NODEFILE.

-np

If not specified, the number of entries found in $PBS_NODEFILE is used. The maximum number of ranks that can be launched is the number of entries in $PBS_NODEFILE.

-pg

The use of the `-pg` option, for having multiple executables on multiple hosts, is allowed but it is up to you to make sure only PBS hosts are specified in the process group file; MPI processes spawned on non-PBS hosts are not guaranteed to be under the control of PBS.

5.2.10.1.ii MPD Startup and Shutdown

The PBS `mpirun` interface starts MPD daemons on each of the unique hosts listed in $PBS_NODEFILE, using either the `rsh` or `ssh` method, based on value of environment variable RSHCOMMAND. The default is `rsh`. The interface also takes care of shutting down the MPD daemons at the end of a run.

If the MPD daemons are not running, the PBS interface to `mpirun` starts MX's MPD daemons as you on the allocated PBS hosts. The MPD daemons may already have been started by the administrator or by you. MPD daemons are not started inside a PBS prologue script since it won't have the path of `mpirun` that you executed (GM or MX), which would determine the path to the MPD binary.

5.2.10.1.iii Examples

Example 5-22: Run a single-executable MPICH-MX job with 64 processes spread out across the PBS-allocated hosts listed in $PBS_NODEFILE:

$PBS_NODEFILE:

```
pbs-host1
pbs-host2
...
pbs-host64
```

```
qsub -l select=64:ncpus=1 -lplace=scatter
[MPICH-MX-HOME]/bin/mpirun -np 64 /path/myprog.x 1200
^D
<job ID>
```

If the MPD daemons are not running, the PBS interface to mpirun starts MX's MPD daemons as you on the allocated PBS hosts. The MPD daemons may be already started by the administrator or by you.

Example 5-23: Run an MPICH-MX job with multiple executables on multiple hosts listed in the process group file procgrp:

```
qsub -l select=2:ncpus=1
echo  "pbs-host1 1 username /x/y/a.exe arg1 arg2" > procgrp
echo  "pbs-host2 1 username /x/x/b.exe arg1 arg2" >> procgrp
[MPICH-MX-HOME]/bin/mpirun -pg procgrp /path/myprog.x 1200
rm -f procgrp
^D
<job ID>
```

mpirun prints a warning message:

```
warning: "-pg" is allowed but it is up to user to make sure only PBS hosts are specified; MPI
    processes spawned are not guaranteed to be under PBS-control
```

The warning is issued because if any of the hosts listed in procgrp are not under the control of PBS, then the processes on those hosts will not be under the control of PBS.

5.2.10.2 Using MPICH-MX and rsh/ssh with PBS

Deprecated. PBS provides an interface to MPICH-MX's mpirun using rsh/ssh. If executed inside a PBS job, this allows for PBS to track all MPICH-MX processes started by rsh/ssh so that PBS can perform accounting and has complete job control. If executed outside of a PBS job, it behaves exactly as if standard mpirun had been used.

You use the same mpirun command as you would use outside of PBS.

5.2.10.2.i Options

Inside a PBS job script, all of the options to the PBS interface are the same as standard mpirun except for the following:

-machinefile <file>

The file argument contents are ignored and replaced by the contents of $PBS_NODEFILE.

-np

If not specified, the number of entries found in the $PBS_NODEFILE is used. The maximum number of ranks that can be launched is the number of entries in $PBS_NODEFILE.

-pg

The use of the -pg option, for having multiple executables on multiple hosts, is allowed but it is up to you to make sure only PBS hosts are specified in the process group file; MPI processes spawned on non-PBS hosts are not guaranteed to be under the control of PBS.

5.2.10.2.ii Examples

Example 5-24: Run a single-executable MPICH-MX job with 64 processes spread out across the PBS-allocated hosts listed in $PBS_NODEFILE:

$PBS_NODEFILE:

```
pbs-host1
pbs-host2
...
pbs-host64
```

```
qsub -l select=64:ncpus=1
mpirun -np 64 /path/myprog.x 1200
^D
<job ID>
```

Example 5-25: Run an MPICH-MX job with multiple executables on multiple hosts listed in the process group file procgrp:

```
qsub -l select=2:ncpus=1
echo  "pbs-host1 1 username /x/y/a.exe arg1 arg2" > procgrp
echo  "pbs-host2 1 username /x/x/b.exe arg1 arg2" >> procgrp
mpirun -pg procgrp /path/myprog.x
rm -f procgrp
^D
<job ID>
```

mpirun prints the warning message:

```
warning: "-pg" is allowed but it is up to user to make sure only PBS hosts are specified; MPI
    processes spawned are not guaranteed to be under PBS-control
```

The warning is issued because if any of the hosts listed in procgrp are not under the control of PBS, then the processes on those hosts will not be under the control of PBS.

5.2.10.3 Restrictions

The maximum number of ranks that can be launched under integrated MPICH-MX is the number of entries in $PBS_NODEFILE.

5.2.11 MPICH2 with PBS on Linux

On Linux, PBS provides an interface to MPICH2's mpirun. If executed inside a PBS job, this allows for PBS to track all MPICH2 processes so that PBS can perform accounting and have complete job control. If executed outside of a PBS job, it behaves exactly as if standard MPICH2's mpirun had been used.

You use the same mpirun command as you would use outside of PBS.

When submitting PBS jobs under the PBS interface to MPICH2's mpirun, be sure to explicitly specify the actual number of ranks or MPI tasks in the qsub select specification. Otherwise, jobs will fail to run with "too few entries in the machinefile".

For instance, the following erroneous specification:

```
#PBS -l select=1:ncpus=1:host=hostA+1:ncpus=2:host=hostB
mpirun -np 3 /tmp/mytask
```

results in this $PBS_NODEFILE listing:

```
hostA
hostB
```

which conflicts with the "`-np 3`" specification in `mpirun` as only two MPD daemons are started.

The correct way is to specify either of the following:

```
#PBS -l select=1:ncpus=1:host=hostA+2:ncpus=1:host=hostB
#PBS -l select=1:ncpus=1:host=hostA+1:ncpus=2:host=hostB:mpiprocs=2
```

which causes $PBS_NODEFILE to contain:

```
hostA
hostB
hostB
```

and this is consistent with "`mpirun -np 3`".

5.2.11.1 Options

If executed inside a PBS job script, all of the options to the PBS interface are the same as MPICH2's `mpirun` except for the following:

-host, -ghost

For specifying the execution host to run on. Ignored.

-machinefile <file>

The file argument contents are ignored and replaced by the contents of $PBS_NODEFILE.

-localonly <number of processes>

For specifying the *number of processes* to run locally. Not supported. You are advised instead to use the equivalent arguments:

"`-np <x> -localonly`".

-np

If you do not specify a `-np` option, then no default value is provided by the PBS interface to MPICH2. It is up to the standard `mpirun` to decide what the reasonable default value should be, which is usually 1. The maximum number of ranks that can be launched is the number of entries in $PBS_NODEFILE.

5.2.11.2 MPD Startup and Shutdown

The interface ensures that the MPD daemons are started on each of the hosts listed in $PBS_NODEFILE. It also ensures that the MPD daemons are shut down at the end of MPI job execution.

5.2.11.3 Examples

Example 5-26: Run a single-executable MPICH2 job with six processes spread out across the PBS-allocated hosts listed in $PBS_NODEFILE. Only three hosts are available:

$PBS_NODEFILE:

```
pbs-host1
pbs-host2
pbs-host3
pbs-host1
pbs-host2
pbs-host3
```

Job.script:

```
# mpirun runs 6 processes, scattered over 3 hosts
# listed in $PBS_NODEFILE
mpirun -np 6 /path/myprog.x 1200
```

Run job script:

```
qsub -l select=6:ncpus=1 -lplace = scatter job.script
<job ID>
```

Example 5-27: Run an MPICH2 job with multiple executables on multiple hosts using $PBS_NODEFILE and `mpiexec` arguments in `mpirun`:

$PBS_NODEFILE:

```
hostA
hostA
hostB
hostB
hostC
hostC
```

Job script:

```
#PBS -l select=3:ncpus=2:mpiprocs=2
mpirun -np 2 /tmp/mpitest1 : -np 2 /tmp/mpitest2 : -np 2 /tmp/mpitest3
```

Run job:

```
qsub job.script
```

Example 5-28: Run an `MPICH2` job with multiple executables on multiple hosts using `mpirun -configfile` option and $PBS_NODEFILE:

$PBS_NODEFILE:

```
hostA
hostA
hostB
hostB
hostC
hostC
```

Job script:

```
#PBS -l select=3:ncpus=2:mpiprocs=2
echo "-np 2 /tmp/mpitest1" > my_config_file
echo "-np 2 /tmp/mpitest2" >> my_config_file
echo "-np 2 /tmp/mpitest3" >> my_config_file
mpirun -configfile my_config_file
rm -f my_config_file
```

Run job:

```
qsub job.script
```

5.2.11.4 Restrictions

The maximum number of ranks that can be launched under integrated MPICH2 is the number of entries in $PBS_NODEFILE.

5.2.12 MPICH2 1.4.1p1 On Windows with PBS

On Windows PBS supplies a wrapper script for MPICH2 1.4.1p1 called `pbs_mpich2_mpirun.bat`, located in `$PBS_EXEC\bin`. You call this script instead of MPICH2 `mpirun`. All options are passed through the script to `mpirun`.

5.2.13 MVAPICH with PBS

The wrapper is **deprecated**. PBS provides an `mpirun` interface to the MVAPICH `mpirun`. When you use the PBS-supplied `mpirun`, PBS can track all MVAPICH processes, perform accounting, and have complete job control. Your PBS administrator can integrate MVAPICH with PBS so that you can use the PBS-supplied `mpirun` in place of the MVAPICH `mpirun` in your job scripts.

MVAPICH allows your jobs to use InfiniBand.

5.2.13.1 Interface to MVAPICH `mpirun` Command

If executed outside of a PBS job, the PBS-supplied interface to `mpirun` behaves exactly as if standard MVAPICH `mpirun` had been used.

If executed inside a PBS job script, all of the options to the PBS interface are the same as MVAPICH's `mpirun` except for the following:

-map
: The `map` option is ignored.

-machinefile <file>
: The `machinefile` option is ignored.

-exclude
: The `exclude` option is ignored.

-np
: If you do not specify a `-np` option, then PBS uses the number of entries found in $PBS_NODEFILE. The maximum number of ranks that can be launched is the number of entries in $PBS_NODEFILE.

5.2.13.2 Examples

Example 5-29: Run a single-executable MVAPICH job with six ranks spread out across the PBS-allocated hosts listed in $PBS_NODEFILE:

$PBS_NODEFILE:

```
pbs-host1
pbs-host1
pbs-host2
pbs-host2
pbs-host3
pbs-host3
```

Contents of job.script:

```
# mpirun runs 6 processes mapped one to each line in $PBS_NODEFILE
mpirun -np 6 /path/myprog
```

Run job script:

```
qsub -l select=3:ncpus=2:mpiprocs=2 job.script
<job ID>
```

5.2.13.3 Restrictions

The maximum number of ranks that can be launched under integrated MVAPICH is the number of entries in $PBS_NODEFILE.

5.2.14 MVAPICH2 with PBS

PBS provides an `mpiexec` interface to MVAPICH2's `mpiexec`. When you use the PBS-supplied `mpiexec`, PBS can track all MVAPICH2 processes, perform accounting, and have complete job control. Your PBS administrator can integrate MVAPICH2 with PBS so that you can use the PBS-supplied `mpirun` in place of the MVAPICH2 `mpirun` in your job scripts.

MVAPICH2 allows your jobs to use InfiniBand.

5.2.14.1 Interface to MVAPICH2 `mpiexec` Command

If executed outside of a PBS job, it behaves exactly as if standard MVAPICH2's `mpiexec` had been used.

If executed inside a PBS job script, all of the options to the PBS interface are the same as MVAPICH2's `mpiexec` except for the following:

-host

The `host` option is ignored.

-machinefile <file>

The `file` option is ignored.

-mpdboot

If `mpdboot` is not called before `mpiexec`, it is called automatically before `mpiexec` runs so that an MPD daemon is started on each host assigned by PBS.

5.2.14.2 MPD Startup and Shutdown

The interface ensures that the MPD daemons are started on each of the hosts listed in $PBS_NODEFILE. It also ensures that the MPD daemons are shut down at the end of MPI job execution.

5.2.14.3 Examples

Example 5-30: Run a single-executable MVAPICH2 job with six ranks on hosts listed in $PBS_NODEFILE:

$PBS_NODEFILE:

```
pbs-host1
pbs-host1
pbs-host2
pbs-host2
pbs-host3
pbs-host3
```

Job.script:

```
mpiexec -np 6 /path/mpiprog
```

Run job script:

```
qsub -l select=3:ncpus=2:mpiprocs=2 job.script
<job ID>
```

Example 5-31: Launch an MVAPICH2 MPI job with multiple executables on multiple hosts listed in the default file "`mpd.hosts`". Here, run executables prog1 and prog2 with two ranks of prog1 on host1, two ranks of prog2 on host2 and two ranks of prog2 on host3, all specified on the command line:

$PBS_NODEFILE:

```
pbs-host1
pbs-host1
pbs-host2
pbs-host2
pbs-host3
pbs-host3
```

Job.script:

```
mpiexec -n 2 prog1 : -n 2  prog2 : -n 2  prog2
```

Run job script:

```
qsub -l select=3:ncpus=2:mpiprocs=2 job.script
<job ID>
```

Example 5-32: Launch an MVAPICH2 MPI job with multiple executables on multiple hosts listed in the default file "`mpd.hosts`". Run executables prog1 and prog2 with two ranks of prog1 on host1, two ranks of prog2 on host2 and two ranks of prog2 on host3, all specified using the `-configfile` option:

$PBS_NODEFILE:

```
pbs-host1
pbs-host1
pbs-host2
pbs-host2
pbs-host3
pbs-host3
```

Job.script:

```
echo "-n 2 -host host1 prog1" > /tmp/jobconf
echo "-n 2 -host host2 prog2" >> /tmp/jobconf
echo "-n 2 -host host3 prog2" >> /tmp/jobconf
mpiexec -configfile /tmp/jobconf
rm /tmp/jobconf
```

Run job script:

```
qsub -l select=3:ncpus=2:mpiprocs=2 job.script
<job ID>
```

5.2.14.4 Restrictions

The maximum number of ranks that can be launched under MVAPICH2 is the number of entries in $PBS_NODEFILE.

5.2.15 Open MPI with PBS

Open MPI can be integrated with PBS on Linux so that PBS can track resource usage, signal processes, and perform accounting, for all job processes. Your PBS administrator can integrate Open MPI with PBS.

5.2.15.1 Using Open MPI with PBS

You can run jobs under PBS using Open MPI without making any changes to your MPI command line.

5.2.16 Platform MPI with PBS

Platform MPI can be integrated with PBS on Linux so that PBS can track resource usage, signal processes, and perform accounting, for all job processes. Your PBS administrator can integrate Platform MPI with PBS.

5.2.16.1 Using Platform MPI with PBS

You can run jobs under PBS using Platform MPI without making any changes to your MPI command line.

5.2.16.2 Setting up Your Environment

In order to override the default `rsh`, set PBS_RSHCOMMAND in your job script:

```
export PBS_RSHCOMMAND=<rsh command>
```

5.2.17 HPE MPI with PBS

PBS supplies its own `mpiexec` to use with HPE MPI on a multi-vnode machine running supported versions of HPE MPI. When you use the PBS-supplied `mpiexec`, PBS can track resource usage, signal processes, and perform accounting, for all job processes. The PBS `mpiexec` provides the standard `mpiexec` interface.

See your PBS administrator to find out whether your system is configured for the PBS `mpiexec`.

5.2.17.1 Using HPE MPI with PBS

You can launch an MPI job on a single HPE system, or across multiple HPE systems. For MPI jobs across multiple HPE systems, PBS will manage the multi-host jobs. For example, if you have two HPE systems named host1 and host2, and want to run two applications called `mympi1` and `mympi2` on them, you can put this in your job script:

```
mpiexec -host host1 -n 4 mympi1 : -host host2 -n 8 mympi2
```

PBS will manage and track the job's processes. When the job is finished, PBS will clean up after it.

You can run MPI jobs in the placement sets chosen by PBS.

5.2.17.2 Prerequisites

In order to use MPI within a PBS job with HPE MPI, you may need to add the following in your job script before you call MPI:

```
module load mpt
```

5.2.17.3 Fitting Jobs onto Nodeboards

PBS will try to put a job that fits in a single nodeboard on just one nodeboard. However, if the only CPUs available are on separate nodeboards, and those vnodes are not allocated exclusively to existing jobs, and the job can share a vnode, then the job is run on the separate nodeboards.

5.2.17.4 Checkpointing and Suspending Jobs

Jobs are suspended on the HPE systems using the PBS suspend feature.

Jobs are checkpointed on HPE systems using application-level checkpointing. There is no OS-level checkpoint.

Suspended or checkpointed jobs will resume on the original nodeboards.

5.2.17.5 Using CSA

PBS support for CSA on HPE systems is no longer available. The CSA functionality for HPE systems has been **removed** from PBS.

5.3 Using PVM with PBS

You use the `pvmexec` command to execute a Parallel Virtual Machine (PVM) program. PVM is not integrated with PBS; PBS is limited to monitoring, controlling, and accounting for job processes only on the primary vnode.

5.3.1 Arguments to `pvmexec` Command

The `pvmexec` command expects a `hostfile` argument for the list of hosts on which to spawn the parallel job.

5.3.2 Using PVM Daemons

To start the PVM daemons on the hosts listed in $PBS_NODEFILE:

1. Start the PVM console on the first host in the list
2. Print the hosts to the standard output file named `jobname.o<PBS job ID>`:

```
echo conf | pvm $PBS_NODEFILE
```

To quit the PVM console but leave the PVM daemons running:

```
quit
```

To stop the PVM daemons, restart the PVM console, and quit:

```
echo halt | pvm
```

5.3.3 Submitting a PVM Job

To submit a PVM job to PBS, use the following:

qsub <job script>

5.3.4 Examples

Example 5-33: To submit a PVM job to PBS, use the following:

```
qsub  your_pvm_job
```

Here is an example script for your_pvm_job:

```
#PBS -N pvmjob
#PBS -V
cd $PBS_O_WORKDIR
echo conf   | pvm $PBS_NODEFILE
echo quit | pvm
./my_pvm_program
echo halt | pvm
```

Example 5-34: Sample PBS script for a PVM job:

```
#PBS -N pvmjob
#
pvmexec a.out -inputfile data_in
```

5.4 Using OpenMP with PBS

PBS Professional supports OpenMP applications by setting the OMP_NUM_THREADS variable in the job's environment, based on the resource request of the job. The OpenMP run-time picks up the value of OMP_NUM_THREADS and creates threads appropriately.

MoM sets the value of OMP_NUM_THREADS based on the first chunk of the `select` statement. If you request ompthreads in the first chunk, MoM sets the environment variable to the value of ompthreads. If you do not request ompthreads in the first chunk, then OMP_NUM_THREADS is set to the value of the ncpus resource of that chunk. If you do not request either ncpus or ompthreads for the first chunk of the select statement, then OMP_NUM_THREADS is set to *1*.

You cannot directly set the value of the OMP_NUM_THREADS environment variable; MoM will override any setting you attempt.

See "Resources Built Into PBS" on page 265 of the PBS Professional Reference Guide for a definition of the ompthreads resource.

Example 5-35: Submit an OpenMP job as a single chunk, for a two-CPU, two-thread job requiring 10gb of memory:

```
qsub -l select=1:ncpus=2:mem=10gb
```

Example 5-36: Run an MPI application with 64 MPI processes, and one thread per process:

```
#PBS -l select=64:ncpus=1
mpiexec -n 64 ./a.out
```

Example 5-37: Run an MPI application with 64 MPI processes, and four OpenMP threads per process:

```
#PBS -l select=64:ncpus=4
mpiexec -n 64 omplace -nt 4 ./a.out
```

or

```
#PBS -l select=64:ncpus=4:ompthreads=4
mpiexec -n 64 omplace -nt 4 ./a.out
```

5.4.1 Running Fewer Threads than CPUs

You might be running an OpenMP application on a host and wish to run fewer threads than the number of CPUs requested. This might be because the threads need exclusive access to shared resources in a multi-core processor system, such as to a cache shared between cores, or to the memory shared between cores.

Example 5-38: You want one chunk, with 16 CPUs and eight threads:

```
qsub -l select=1:ncpus=16:ompthreads=8
```

5.4.2 Running More Threads than CPUs

You might be running an OpenMP application on a host and wish to run more threads than the number of CPUs requested, perhaps because each thread is I/O bound.

Example 5-39: You want one chunk, with eight CPUs and 16 threads:

```
qsub -l select=1:ncpus=8:ompthreads=16
```

5.4.3 Caveats for Using OpenMP with PBS

Make sure that you request the correct number of MPI ranks for your job, so that the PBS node file contains the correct number of entries. See section 5.1.3, "Specifying Number of MPI Processes Per Chunk", on page 80.

5.5 Hybrid MPI-OpenMP Jobs

For jobs that are both MPI and multi-threaded, the number of threads per chunk, for all chunks, is set to the number of threads requested (explicitly or implicitly) in the first chunk, except for MPIs that have been integrated with the PBS TM API.

For MPIs that are integrated with the PBS TM interface, (Open MPI), you can specify the number of threads separately for each chunk, by specifying the ompthreads resource separately for each chunk.

For most MPIs, the OMP_NUM_THREADS and NCPUS environment variables default to the number of ncpus requested for the first chunk.

Should you have a job that is both MPI and multi-threaded, you can request one chunk for each MPI process, or set mpiprocs to the number of MPI processes you want on each chunk. See section 5.1.3, "Specifying Number of MPI Processes Per Chunk", on page 80.

5.5.1 Examples

Example 5-40: To request four chunks, each with one MPI process, two CPUs and two threads:

```
qsub -l select=4:ncpus=2
```

or

```
qsub -l select=4:ncpus=2:ompthreads=2
```

Example 5-41: To request four chunks, each with two CPUs and four threads:

```
qsub -l select=4:ncpus=2:ompthreads=4
```

Example 5-42: To request 16 MPI processes each with two threads on machines with two processors:

```
qsub -l select=16:ncpus=2
```

Example 5-43: To request two chunks, each with eight CPUs and eight MPI tasks and four threads:

```
qsub -l select=2:ncpus=8:mpiprocs=8:ompthreads=4
```

Example 5-44: For the following:

```
qsub -l select=4:ncpus=2
```

This request is satisfied by four CPUs from VnodeA, two from VnodeB and two from VnodeC, so the following is written to $PBS_NODEFILE:

```
VnodeA
VnodeA
VnodeB
VnodeC
```

The OpenMP environment variables are set, for the four PBS tasks corresponding to the four MPI processes, as follows:

- For PBS task #1 on VnodeA: OMP_NUM_THREADS=2 NCPUS=2
- For PBS task #2 on VnodeA: OMP_NUM_THREADS=2 NCPUS=2
- For PBS task #3 on VnodeB: OMP_NUM_THREADS=2 NCPUS=2
- For PBS task #4 on VnodeC: OMP_NUM_THREADS=2 NCPUS=2

Example 5-45: For the following:

```
qsub -l select=3:ncpus=2:mpiprocs=2:ompthreads=1
```

This is satisfied by two CPUs from each of three vnodes (VnodeA, VnodeB, and VnodeC), so the following is written to $PBS_NODEFILE:

```
VnodeA
VnodeA
VnodeB
VnodeB
VnodeC
VnodeC
```

The OpenMP environment variables are set, for the six PBS tasks corresponding to the six MPI processes, as follows:

- For PBS task #1 on VnodeA: OMP_NUM_THREADS=1 NCPUS=1
- For PBS task #2 on VnodeA: OMP_NUM_THREADS=1 NCPUS=1
- For PBS task #3 on VnodeB: OMP_NUM_THREADS=1 NCPUS=1
- For PBS task #4 on VnodeB: OMP_NUM_THREADS=1 NCPUS=1
- For PBS task #5 on VnodeC: OMP_NUM_THREADS=1 NCPUS=1
- For PBS task #6 on VnodeC: OMP_NUM_THREADS=1 NCPUS=1

Example 5-46: To run two threads on each of N chunks, each running a process, all on the same HPE system:

```
qsub -l select=N:ncpus=2 -l place=pack
```

This starts *N* processes on a single host, with two OpenMP threads per process, because OMP_NUM_THREADS=2.

6 Controlling How Your Job Runs

6.1 Using Job Exit Status

PBS can use the exit status of your job as input to the epilogue, and to determine whether to run a dependent job. If you are running under Linux, make sure that your job's exit status is captured correctly; see section 1.4.2.4, “Capture Correct Job Exit Status”, on page 5.

Job exit codes are listed in section 10.9, "Job Exit Status Codes", on page 469 of the PBS Professional Administrator’s Guide.

The exit status of a job array is determined by the status of each of its completed subjobs, and is only available when all valid subjobs have completed. The individual exit status of a completed subjob is passed to the epilogue, and is available in the 'E' accounting log record of that subjob. See “Job Array Exit Status” on page 160.

6.1.1 Caveats for Exit Status

- Normally, `qsub` exits with the exit status for a blocking job, but if you submit a job that is both blocking and interactive, PBS does not return the job's exit status. See section 6.10, “Making qsub Wait Until Job Ends”, on page 122.
- For a blocking job, the exit status is returned before staging finishes. See section 6.10.2, “Caveats for Blocking Jobs”, on page 123.
- The exit status of an interactive job is always recorded as 0 (zero), regardless of the actual exit status.

6.2 Using Job Dependencies

PBS allows you to specify dependencies between two or more jobs. Dependencies are useful for a variety of tasks, such as:

- Specifying the order in which jobs in a set should execute
- Requesting a job run only if an error occurs in another job
- Holding jobs until a particular job starts or completes execution

There is no limit on the number of dependencies per job.

If you have one or more jobs j2... jN that are dependent on a job j1 so that they can run only after j1 runs, and you delete j1, PBS deletes jobs j2... jN. If you have jobs j2... jN that can run only after j1 has not run successfully, and you delete j1, PBS releases the dependencies for jobs j2... jN so that they can run.

6.2.1 Syntax for Job Dependencies

Use the "`-W depend=<dependency list>`" option to `qsub` to define dependencies between jobs. The *dependency list* has the format:

<type>:<arg list>[,<type>:<arg list> ...]

where except for the on type, the *arg list* is one or more PBS job IDs in the form:

<job ID>[:<job ID> ...]

These are the available dependency types:

after:<arg list>
: This job may start only after all jobs in *arg list* have started execution.

afterok:<arg list>
: This job may start only after all jobs in *arg list* have terminated with no errors.

afternotok:<arg list>
: This job may start only after all jobs in *arg list* have terminated with errors.

afterany:<arg list>
: This job may start after all jobs in *arg list* have finished execution, with or without errors. This job will not run if a job in the *arg list* was deleted without ever having been run.

before:<arg list>
: Jobs in *arg list* may start only after specified jobs have begun execution. You must submit jobs that will run before other jobs with a type of on.

beforeok:<arg list>
: Jobs in *arg list* may start only after this job terminates without errors.

beforenotok:<arg list>
: If this job terminates execution with errors, the jobs in *arg list* may begin.

beforeany:<arg list>
: Jobs in *arg list* may start only after specified jobs terminate execution, with or without errors. Requires use of on dependency for jobs that will run before other jobs.

on:count
: This job may start only after *count* dependencies on other jobs have been satisfied. This type is used in conjunction with one of the before types. *count* is an integer greater than *0*.

runone:<job ID>
: Puts the current job and the job with *job ID* in a set of jobs out of which PBS will eventually run just one. To add a job to a set, specify the job ID of another job already in the set.

The depend job attribute controls job dependencies. You can set it using the `qsub` command line or a PBS directive:

```
qsub -W depend=...
#PBS depend=...
```

6.2.1.1 Running Your Job on First Available Resources

You may want to run a job on whichever resources become available first, even if the job could run on other sets of resources. You may want to start a flexible job as soon as possible on a smaller set of resources rather than waiting longer for a larger set of resources, or you may prefer certain resources but be able to use others (for example, you might prefer a specific processor, but still be able to run on another if that is all that's available).

If you submit a set of jobs where each job has a "runone" dependency on the others, PBS runs only one of the jobs in the "runone set". PBS automatically groups the jobs into a runone set. The jobs in a runone set can run different scripts.

When any of the jobs in the set starts, PBS applies a system hold to the others. The hold on the other jobs is released when the running job is requeued:

- Via `qrerun`
- When node fail requeue is triggered

The other jobs in the set are deleted:

- When a job ends, regardless of its exit status
- When the running job is deleted

To identify a job as a member of the set, give it a "runone" dependency on the previously-submitted member of the set. For example, we have three jobs, each of which runs on different resources. To submit these three jobs as a runone set:

```
qsub -lselect=200:ncpus=16 -lwalltime=1:00:00 myscript.sh
10.myserver
qsub -lselect=100:ncpus=16 -lwalltime=2:00:00 -Wdepend=runone:10 myscript.sh
11.myserver
qsub -lselect=50:ncpus=16 -lwalltime=4:00:00 -Wdepend=runone:10 myscript.sh
12.myserver
```

6.2.2 Job Dependency Examples

Example 6-1: You have three jobs, job1, job2, and job3, and you want job3 to start *after* job1 and job2 have *ended*:

```
qsub job1
16394.jupiter
qsub job2
16395.jupiter
qsub -W depend=afterany:16394:16395 job3
16396.jupiter
```

Example 6-2: You want job2 to start *only if* job1 ends with no errors:

```
qsub job1
16397.jupiter
qsub -W depend=afterok:16397 job2
16396.jupiter
```

Example 6-3: job1 should run before job2 and job3. To use the beforeany dependency, you must use the on dependency:

```
qsub -W depend=on:2 job1
16397.jupiter
qsub -W depend=beforeany:16397 job2
16398.jupiter
qsub -W depend=beforeany:16397 job3
16399.jupiter
```

6.2.3 Job Array Dependencies

Job dependencies are supported:

- Between jobs and jobs
- Between job arrays and job arrays
- Between job arrays and jobs
- Between jobs and job arrays

Job dependencies are not supported for subjobs or ranges of subjobs.

6.2.4 Caveats and Advice for Job Dependencies

6.2.4.1 Correct Exit Status Required

Under Linux, make sure that job exit status is captured correctly; see section 6.1, “Using Job Exit Status”, on page 109.

6.2.4.2 Permission Required for Dependencies

To use the before types, you must have permission to alter the jobs in *arg list*. Otherwise, the dependency is rejected and the new job is aborted.

6.2.4.3 Warning About Job History

Enabling job history changes the behavior of dependent jobs. If a job j1 depends on a finished job j2 for which PBS is maintaining history, PBS releases j1's dependency, and takes appropriate action. If job j1 depends on a finished job j3 that has been purged from job history, j1 is rejected just as in previous versions of PBS where the job was no longer in the system.

6.2.4.4 Error Reporting

PBS checks for errors in the existence, state, or condition of the job after accepting the job. If there is an error, PBS sends you mail about the error and deletes the job.

6.3 Adjusting Job Running Time

This feature was added in PBS Professional 12.0.

6.3.1 Shrink-to-fit Jobs

PBS allows you to submit a job whose running time can be adjusted to fit into an available scheduling slot. The job's minimum and maximum running time are specified in the min_walltime and max_walltime resources. PBS chooses the actual walltime. Any job that requests min_walltime is a **shrink-to-fit** job.

6.3.1.1 Requirements for a Shrink-to-fit Job

A job must have a value for min_walltime to be a shrink-to-fit job. Shrink-to-fit jobs are not required to request max_walltime, but it is an error to request max_walltime and not min_walltime.

Jobs that do not have values for min_walltime are not shrink-to-fit jobs, and you can specify their walltime.

6.3.1.2 Comparison Between Shrink-to-fit and Non-shrink-to-fit Jobs

The only difference between a shrink-to-fit and a non-shrink-to-fit job is how the job's walltime is treated. PBS sets the walltime when it runs the job. Any walltime value that exists before the job runs is ignored.

6.3.2 Using Shrink-to-fit Jobs

If you have jobs that can run for less than the expected time needed and still make useful progress, you can make them shrink-to-fit jobs in order to maximize utilization.

You can use shrink-to-fit jobs for the following:

- Jobs that are internally checkpointed. This includes jobs which are part of a larger effort, where a job does as much work as it can before it is killed, and the next job in that effort takes up where the previous job left off.
- Jobs using periodic PBS checkpointing
- Jobs whose real running time might be much less than the expected time
- When you have dedicated time for system maintenance, and you want to take advantage of time slots right up until shutdown, you can run speculative shrink-to-fit jobs if you can risk having a job killed before it finishes. Similarly, speculative jobs can take advantage of the time just before a reservation starts
- Any job where you do not mind running the job as a speculative attempt to finish some work

6.3.3 Running Time of a Shrink-to-fit Job

6.3.3.1 Setting Running Time Range for Shrink-to-fit Jobs

It is only required that the job request min_walltime to be a shrink-to-fit job. Requesting max_walltime without requesting min_walltime is an error.

You can set the job's running time range by requesting min_walltime and max_walltime, for example:

qsub -l min_walltime=<min walltime>, max_walltime=<max walltime> <job script>

6.3.3.2 Setting walltime for Shrink-to-fit Jobs

For a shrink-to-fit job, PBS sets the walltime resource based on the values of min_walltime and max_walltime, regardless of whether walltime is specified for the job.

PBS examines each shrink-to-fit job when it gets to it, and looks for a time slot whose length is between the job's min_walltime and max_walltime. If the job can fit somewhere, PBS sets the job's walltime to a duration that fits the time slot, and runs the job. The chosen value for walltime is visible in the job's Resource_List.walltime attribute. Any existing walltime value, regardless of where it comes from, e.g. previous execution, is reset to the new calculated running time.

If a shrink-to-fit job is run more than once, PBS recalculates the job's running time to fit an available time slot that is between min_walltime and max_walltime, and resets the job's walltime, each time the job is run.

For a multi-vnode job, PBS chooses a walltime that works for all of the chunks required by the job, and places job chunks according to the placement specification.

6.3.4 Modifying Shrink-to-fit and Non-shrink-to-fit Jobs

6.3.4.1 Modifying min_walltime and max_walltime

You can change min_walltime and/or max_walltime for a shrink-to-fit job by using the `qalter` command. Any changes take effect after the current scheduling cycle. Changes affect only queued jobs; running jobs are unaffected unless they are rerun.

6.3.4.1.i Making Non-shrink-to-fit Jobs into Shrink-to-fit Jobs

You can convert a normal non-shrink-to-fit job into a shrink-to-fit job using the `qalter` command to set values for min_walltime and max_walltime.

Any changes take effect after the current scheduling cycle. Changes affect only queued jobs; running jobs are unaffected unless they are rerun.

6.3.4.1.ii Making Shrink-to-fit Jobs into Non-shrink-to-fit Jobs

To make a shrink-to-fit job into a normal, non-shrink-to-fit job, use the `qalter` command to do the following:

- Set the job's walltime to the value for max_walltime
- Unset min_walltime
- Unset max_walltime

6.3.5 Viewing Running Time for a Job

6.3.5.1 Viewing min_walltime and max_walltime

You can use `qstat -f` to view the values of min_walltime and max_walltime. For example:

```
% qsub -lmin_walltime=01:00:15, max_walltime=03:30:00 job.sh
<job ID>
% qstat -f <job ID>
...
Resource_List.min_walltime=01:00:15
Resource_List.max_walltime=03:30:00
```

You can use `tracejob` to display max_walltime and min_walltime as part of the job's resource list. For example:

```
12/16/2011 14:28:55  A    user=pbsadmin group=Users project=_pbs_project_default
…
    Resource_List.max_walltime=10:00:00
    Resource_List.min_walltime=00:00:10
```

6.3.5.2 Viewing walltime for a Shrink-to-fit Job

PBS sets a job's walltime only when the job runs. While the job is running, you can see its walltime via `qstat -f`. While the job is not running, you cannot see its real walltime; it may have a value set for walltime, but this value is ignored.

You can see the walltime value for a finished shrink-to-fit job if you are preserving job history. See section 10.15, “Managing Job History”, on page 479.

6.3.6 Lifecycle of a Shrink-to-fit Job

6.3.6.1 Execution of Shrink-to-fit Jobs

Shrink-to-fit jobs are started just like non-shrink-to-fit jobs.

6.3.6.2 Termination of Shrink-to-fit Jobs

When a shrink-to-fit job exceeds the walltime PBS has set for it, it is killed by PBS exactly as a non-shrink-to-fit job is killed when it exceeds its walltime.

6.3.7 The min_walltime and max_walltime Resources

max_walltime

Maximum walltime allowed for a shrink-to-fit job. Job's actual walltime is between max_walltime and min_walltime. PBS sets walltime for a shrink-to-fit job. If this resource is specified, min_walltime must also be specified. Must be greater than or equal to min_walltime. Cannot be used for resources_min or resources_max. Cannot be set on job arrays or reservations. If not specified, PBS uses 5 years as the maximum time slot. Can be requested only outside of a select statement. Non-consumable. Default: None. Type: duration. Python type: pbs.duration

min_walltime

Minimum walltime allowed for a shrink-to-fit job. When this resource is specified, job is a shrink-to-fit job. If this attribute is set, PBS sets the job's walltime. Job's actual walltime is between max_walltime and min_walltime. Must be less than or equal to max_walltime. Cannot be used for resources_min or resources_max. Cannot be set on job arrays or reservations. Can be requested only outside of a select statement. Non-consumable. Default: None. Type: duration. Python type: pbs.duration

6.3.8 Caveats and Restrictions for Shrink-to-fit Jobs

It is erroneous to specify max_walltime for a job without specifying min_walltime. If attempted via `qsub` or `qalter`, the following error is printed:

```
'Can not have "max_walltime" without "min_walltime"'
```

It is erroneous to specify a min_walltime that is greater than max_walltime. If attempted via `qsub` or `qalter`, the following error is printed:

```
'"min_walltime" can not be greater than "max_walltime"'
```

Job arrays cannot be shrink-to-fit. You cannot have a shrink-to-fit job array. It is erroneous to specify a min_walltime or max_walltime for a job array. If attempted via `qsub` or `qalter`, the following error is printed:

```
'"min_walltime" and "max_walltime" are not valid resources for a job array'
```

Reservations cannot be shrink-to-fit. You cannot have a shrink-to-fit reservation. It is erroneous to set min_walltime or max_walltime for a reservation. If attempted via `pbs_rsub`, the following error is printed:

```
'"min_walltime" and "max_walltime" are not valid resources for reservation.'
```

It is erroneous to set resources_max or resources_min for min_walltime and max_walltime. If attempted, the following error message is displayed, whichever is appropriate:

```
"Resource limits can not be set for min_walltime"
"Resource limits can not be set for max_walltime"
```

6.4 Using Checkpointing

6.4.1 Prerequisites for Checkpointing

A job is checkpointable if it has not been marked as non-checkpointable and any of the following is true:

- Its application supports checkpointing and your administrator has set up checkpoint scripts
- There is a third-party checkpointing application available
- The OS supports checkpointing

6.4.2 Minimum Checkpoint Interval

The execution queue in which the job resides controls the minimum interval at which a job can be checkpointed. The interval is specified in CPU minutes or walltime minutes. The same value is used for both, so for example if the minimum interval is specified as 12, then a job using the queue's interval for CPU time is checkpointed every 12 minutes of CPU time, and a job using the queue's interval for walltime is checkpointed every 12 minutes of walltime.

6.4.3 Syntax for Specifying Checkpoint Interval

Use the "`-c checkpoint-spec`" option to `qsub` to specify the interval, in CPU minutes, or in walltime minutes, at which the job will be checkpointed.

The *checkpoint-spec* argument is specified as:

c
: Job is checkpointed at the interval, measured in CPU time, set on the execution queue in which the job resides.

c=<minutes of CPU time>
: Job is checkpointed at intervals of the specified number of minutes of CPU time used by the job. This value must be greater than zero. If the interval specified is less than that set on the execution queue in which the job resides, the queue's interval is used.

  Format: *Integer*

w
: Job is checkpointed at the interval, measured in walltime, set on the execution queue in which the job resides.

w=<minutes of walltime>
: Checkpointing is to be performed at intervals of the specified number of minutes of walltime used by the job. This value must be greater than zero. If the interval specified is less than that set on the execution queue in which the job resides, the queue's interval is used.

  Format: *Integer*

n
: Job is not checkpointed.

s
: Job is checkpointed only when the PBS server is shut down.

u
: Checkpointing is unspecified, and defaults to the same behavior as "`s`".

The Checkpoint job attribute controls the job's checkpoint interval. You can set it using the `qsub` command line or a PBS directive:

Use `qsub` to specify that the job should use the execution queue's checkpoint interval:

```
qsub -c c my_job
```

Use a directive to checkpoint the job every 10 minutes of CPU time:

```
#PBS -c c=10
```

6.4.4 Using Checkpointing for Preempting or Holding Jobs

Your site may need to preempt jobs while they are running, or you may want to be able to place a hold your job while it runs. To allow either of these, make your job checkpointable. This means that you should not mark it as non-checkpointable (do not use `qsub -c n`), your application must be checkpointable or there is a third-party checkpointing application, and your administrator must supply a checkpoint script to be run by the MoM where the job runs.

You can use application-level checkpointing when your job is preempted or you place a hold on it to save the partial results. When your checkpointed job is restarted, your job script can find that the job was checkpointed, and can start from the checkpoint file instead of starting from scratch.

If you try to hold a running job that is not checkpointable (either it is marked as non-checkpointable or the script is missing or returns failure), the job continues to run with its Hold_Types attribute set to *h*. See section 6.5, "Holding and Releasing Jobs", on page 117.

6.4.5 Caveats and Restrictions for Checkpointing

- Checkpointing is not supported for job arrays.
- If you do not specify `qsub -c checkpoint-spec`, it is unspecified, and defaults to the same as "`s`".
- PBS limits the number of times it tries to run a job to 21, and tracks this count in the job's run_count attribute. If your job is checkpointed and requeued enough times, it will be held.

6.5 Holding and Releasing Jobs

You can place a hold on your job to do the following:

- A queued job remains queued until you release the hold; see section 6.5.3, "Holding a Job Before Execution", on page 118
- A running job stops running but can resume where it left off; see section 6.5.4.1, "Checkpointing and Requeueing the Job", on page 118
- A running job continues to run but is held if it is requeued; see section 6.5.4.2, "Setting Hold Type for a Running Job", on page 118

You hold a job using the qhold command; see "qhold" on page 150 of the PBS Professional Reference Guide.

You can release a held queued job to make it eligible to be scheduled to run, and you can release a hold on a running job. You release a hold on your job using the qrls command; see "qrls" on page 183 of the PBS Professional Reference Guide.

The qhold command uses the following syntax:

qhold [-h <hold list>] <job ID> [<job ID> ...]

The qrls command uses the following syntax:

qrls [-h <hold list>] <job ID> [<job ID> ...]

For a job array the *job ID* must be enclosed in double quotes.

6.5.1 Types of Holds

The *hold list* specifies the types of holds to be placed on the job. The *hold list* argument is a string consisting of one or more of the letters `u`, `p`, `o`, or `s` in any combination, or the letter `n`. The following table shows the hold type associated with each letter:

Table 6-1: Hold Types

Hold Type	Meaning	Who Can Set or Release
u	*User*	*Job owner, Operator, Manager, administrator, root*
o	*Other*	*Operator, Manager, administrator, root*

Table 6-1: Hold Types

Hold Type	Meaning	Who Can Set or Release
s	*System*	*Manager, administrator, root, PBS (dependency)*
n	*No hold*	*Job owner, Operator, Manager, administrator, root*
p	*Bad password*	*Administrator, root*

If no -h option is specified, PBS applies a *user* hold to the jobs listed in the *job ID* list.

If a job in the *job ID* list is in the queued, held, or waiting states, the only change is that the hold type is added to the job's other holds. If the job is queued or waiting in an execution queue, the job is also put in the held state.

6.5.2 Requirements for Holding or Releasing a Job

The user executing the `qhold` or `qrls` command must have the necessary privilege to apply a hold or release a hold. The same rules apply for releasing a hold and for for setting a hold.

6.5.3 Holding a Job Before Execution

Normally, PBS runs your job as soon as an appropriate slot opens up. However, you can tell PBS that the job is ineligible to run and should remain queued. Use the "`-h`" option to `qsub` to apply a *user hold* to the job when you submit it. PBS accepts the job and places it in the *held* state. The job remains held and ineligible to run until the hold is released.

The Hold_Types job attribute controls the job's holding behavior; set it via `qsub` or a directive:

```
qsub -h my_job
#PBS -h
```

6.5.4 Holding a Job During Execution

6.5.4.1 Checkpointing and Requeueing the Job

If your job is checkpointable, you can stop its execution by holding it. In this case the following happens:

- The job is checkpointed
- The resources assigned to the job are released
- The job is put back in the execution queue in the Held state

See section 6.4.1, “Prerequisites for Checkpointing”, on page 115.

To hold your job, use the `qhold` command:

```
qsub -h my_job
```

6.5.4.2 Setting Hold Type for a Running Job

If your job is not checkpointable, `qhold` merely sets the job's Hold_Types attribute. This has no effect unless the job is requeued with the `qrerun` command. In that case the job remains queued and ineligible to run until you release the hold.

6.5.5 Releasing a Job

You can release one or more holds on a job by using the `qrls` command.

The `qrls` command uses the following syntax:

qrls [-h <hold list>] <job ID> ...

For job arrays, the *job ID* must be enclosed in double quotes.

If you try to release a hold on a job which is not held, the `qrls` command is ignored. If you use the `qrls` command to release a hold on a job that had been previously running and was checkpointed, the hold is released and the job is returned to the queued (Q) state, and the job becomes eligible to be scheduled to run when resources come available.

The `qrls` command does not run the job; it simply releases the hold and makes the job eligible to be run the next time the scheduler selects it.

6.5.6 Caveats and Restrictions for Holding and Releasing Jobs

- The `qhold` command can be used on job arrays, but not on subjobs or ranges of subjobs. On job arrays, the `qhold` command can be applied only in the 'Q', 'B' or 'W' states. This will put the job array in the 'H', held, state. If any subjobs are running, they will run to completion. Job arrays cannot be moved in the 'H' state if any subjobs are running.
- Checkpointing is not supported for job arrays. Even on systems that support checkpointing, no subjobs will be checkpointed; they will run to completion.
- To hold a running job and stop its execution, the job must be checkpointable. See section 6.4.1, “Prerequisites for Checkpointing”, on page 115.
- The `qrls` command can only be used with job array objects, not with subjobs or ranges. The job array will be returned to its pre-hold state, which can be either 'Q', 'B', or 'W'.
- The `qhold` command can only be used with job array objects, not with subjobs or ranges. A hold can be applied to a job array only from the 'Q', 'B' or 'W' states. This will put the job array in the 'H', held, state. If any subjobs are running, they will run to completion. No queued subjobs will be started while in the 'H' state.
- PBS limits the number of times it tries to run a job to 21, and tracks this count in the job's run_count attribute. If your job is checkpointed and requeued enough times, it will be held.

6.5.7 Why is Your Job Held?

Your job may be held for any of the following reasons:

- Provisioning fails due to invalid provisioning request or to internal system error ("s")
- After provisioning, the AOE reported by the vnode does not match the AOE requested by the job ("s")
- The job was held by a PBS Manager or Operator ("o")
- The job was checkpointed and requeued ("s")
- Your job depends on a finished job for which PBS is maintaining history ('s")
- The job's password is invalid ("p")
- The job's run_count attribute has a value greater than 20.

6.5.8 Examples of Holding and Releasing Jobs

The following examples illustrate how to use both the `qhold` and `qrls` commands. Notice that the state ("S") column shows how the state of the job changes with the use of these two commands.

```
qstat -a 54

                                                  Req'd  Elap
Job ID   User   Queue Jobname Sess NDS TSK Mem Time S Time
-------- ------ ----- ------- ---- --- --- --- ---- - ----
54.south barry  workq  engine  --   --   1  -- 0:20 Q  --

qhold 54
qstat -a 54

                                                  Req'd  Elap
Job ID   User   Queue Jobname Sess NDS TSK Mem Time S Time
-------- ------ ----- ------- ---- --- --- --- ---- - ----
54.south barry  workq  engine  --   --   1  -- 0:20 H  --

qrls -h u 54
qstat -a 54

                                                  Req'd  Elap
Job ID   User   Queue Jobname Sess NDS TSK Mem Time S Time
-------- ------ ----- ------- ---- --- --- --- ---- - ----
54.south barry  workq  engine  --   --   1  -- 0:20 Q  --
```

6.6 Allowing Your Job to be Re-run

You can specify whether or not your job is eligible to be re-run if for some reason the job is terminated before it finishes. Use the "`-r`" option to `qsub` to specify whether the job is rerunnable. The argument to this option is "*y*", meaning that the job can be re-run, or "*n*", meaning that it cannot. If you do not specify whether or not your job is rerunnable, it is rerunnable.

If running your job more than once would cause a problem, mark your job as non-rerunnable. Otherwise, leave it as rerunnable . The purpose of marking a job as non-rerunnable is to prevent it from starting more than once.

If a job that is marked non-rerunnable has an error during startup, before it begins execution, that job is requeued for another attempt.

The Rerunable job attribute controls whether the job is rerunnable; you can set it via `qsub` or a PBS directive:

```
qsub -r n my_job
#PBS -r n
```

The following table lists the circumstances where the job's Rerunable attribute makes a difference or does not:

Table 6-2: When does Rerunable Attribute Matter?

Circumstance	Rerunnable	Not Rerunnable
Job fails upon startup, before running	Job is requeued	Job is requeued
Job is running on multiple hosts, and one host goes down	Job is requeued	Job is deleted
Job is scheduled to run on multiple hosts, and did not start on at least one host	Job is requeued	Job is requeued
Server is shut down with a delay	Job is requeued	Job finishes
Server is shut down immediately	Job is requeued	Job is deleted
Job requests provisioning and provisioning script fails	Job is requeued	Job is requeued
Job is running on multiple hosts and one host becomes busy due to console activity	Job is requeued	Job is deleted
Higher-priority job needs resources	Job may be requeued	Job may be deleted

6.6.1 Caveats and Restrictions for Marking Jobs as Rerunnable

- Interactive jobs are not rerunnable.
- Job arrays are required to be rerunnable. PBS will not accept a job array that is marked as not rerunnable. You can submit a job array without specifying whether it is rerunnable, and PBS will automatically mark it as rerunnable.
- Mark your job as not rerunnable only if running it more than once would cause a problem. If your job is marked as not rerunnable, and a higher-priority job needs resources, your job could be deleted.

6.7 Controlling Number of Times Job is Re-run

PBS has a built-in limit of 21 on the number of times it will try to run your job. The number of attempts is tracked in the job's run_count attribute. By default, the value of run_count is zero at job submission. The job is held when the value of run_count goes above 20.

You can reduce the number of times PBS attempts to run your job. You can specify a non-negative value for run_count at job submission, and you can use `qalter` to raise the value of run_count while the job is running. You cannot give a job more retries than the limit, and you cannot lower the value of run_count while the job is running.

6.7.1 Caveats for Raising Value of run_count Attribute

If your job is checkpointed and requeued enough times, it will be held.

6.8 Deferring Execution

Normally, PBS runs your job as soon as an appropriate slot opens up. Instead, you can specify a time after which the job is eligible to run. The job is in the wait (W) state from the time it is submitted until the time it is eligible for execution.

6.8.1 Syntax for Deferring Execution

Use the "`-a <datetime>`" option to `qsub` to specify the time after which the job is eligible for execution. The *datetime* argument is in the form:

[[[[CC]YY]MM]DD]hhmm[.SS]

where

CC is the first two digits of the year (the century): optional

YY is the second two digits of the year: optional

MM is the two digits for the month: optional

DD is the day of the month: optional

hh is the hour

mm is the minute

SS is the seconds: optional

If the day *DD* is in the future, and the month *MM* is not specified, the month defaults to the current month. If the day *DD* is in the past, and the month *MM* is not specified, the month is set to next month. For example, if today is the 10th, and you specify the 12th but no month, your job is eligible to run two days from today, on the 12th.

Similarly, if the time *hhmm* is in the future, and the day *DD* is not specified, the day defaults to the current day. If the time *hhmm* is in the past, and the day *DD* is not specified, the day is set to tomorrow. For example, if you submit a job at 11:15am with a time of "`1110`", the job will be eligible to run at 11:10am tomorrow.

The job's Execution_Time attribute controls deferred execution. You can set it using either of the following:

```
qsub -a 0700 my_job
#PBS -a 10220700
```

6.9 Setting Priority for Your Job

PBS includes a place in each job where you can specify the job's priority. Your administrator may or may not choose to use this priority value when scheduling jobs. Use the "`-p <priority>`" to specify the priority of the job. The *priority* argument must be an integer between -1024 (lowest priority) and +1023 (highest priority) inclusive. The default is unset, which is equivalent to zero.

The Priority job attribute contains the value you specify. Set it via `qsub` or a directive:

```
qsub -p 120 my_job
#PBS -p -300
```

If you need an absolute ordering of your own jobs, see section 6.2, “Using Job Dependencies”, on page 109.

6.10 Making `qsub` Wait Until Job Ends

Normally, when you submit a job, the `qsub` command exits after returning the ID of the new job. You can use the "`-W block=true`" option to `qsub` to specify that you want `qsub` to "block", meaning wait for the job to complete and report the exit value of the job.

If your job is successfully submitted, `qsub` blocks until the job terminates or an error occurs. If job submission fails, no special processing takes place.

If the job runs to completion, qsub exits with the exit status of the job. For job arrays, blocking qsub waits until the entire job array is complete, then returns the exit status of the job array.

The block job attribute controls blocking. Set it either via qsub or a PBS directive:

```
qsub -W block=true
#PBS -W block=true
```

6.10.1 Signal Handling and Error Processing for Blocking Jobs

Signals SIGQUIT and SIGKILL are not trapped, and immediately terminate the qsub process, leaving the associated job either running or queued.

If qsub receives one of the signals SIGHUP, SIGINT, or SIGTERM, it prints a message and then exits with an exit status of *2*.

If the job is deleted before running to completion, or an internal PBS error occurs, qsub prints an an error message describing the situation to this error stream and qsub exits with an exit status of *3*.

6.10.2 Caveats for Blocking Jobs

- If you submit a job that is both blocking and interactive, the job's exit status is not returned at the end of the job.
- PBS returns the exit status of a blocking job before staging finishes for the job. To see whether the job is still staging, use qstat -f, and look at the job's substate attribute. This attribute has value *51* when files are staging out.

6.11 Running Your Job Interactively

PBS provides a special kind of batch job called an *interactive-batch job* or *interactive job*. An interactive job is treated just like a regular batch job in that it is queued up, and has to wait for resources to become available before it can run. However, once it starts, your terminal input and output are connected to the job similarly to a login session. It appears that you are logged into one of the available execution machines, and the resources requested by the job are reserved for that job. This is useful for debugging applications or for computational steering.

You can use GUI applications in interactive jobs on remote hosts. The PBS interface is slightly different on Linux and Windows. For Linux, see section 6.11.9, “Receiving X Output from Interactive Linux Jobs”, on page 126. For Windows, see section 6.11.10, “Submitting Interactive GUI Jobs on Windows”, on page 127.

Interactive jobs can use provisioning.

6.11.1 Input and Output for Interactive Jobs

An interactive job comes complete with a pseudotty suitable for running commands that set terminal characteristics. Once the interactive job has started execution, input to and output from the job pass through qsub. You provide all input to your interactive job through the terminal session in which the job runs.

For interactive jobs, you can specify PBS directives in a job script. You cannot provide commands to the job by using a job script. For interactive jobs, PBS ignores executable commands in job scripts.

6.11.2 Running Your Interactive Job

To run your job interactively, you can do either of the following:

- Use `qsub -I` at the command line
- Use `#PBS interactive=true (deprecated)` in a PBS directive

When your interactive job is running, you can run commands, executables, shell scripts, DOS commands, etc. These commands behave normally; for example, if the path to a command is not in your PATH environment variable, you must provide the full path.

6.11.3 Lifecycle of an Interactive Job

1. You start the interactive job using `qsub` `#PBS interactive=true (deprecated)` or `-I`
2. If there is a script, PBS processes any directives in the script
3. The scheduler runs the job
4. Output is connected to the submission window
5. You run commands, executables, shell scripts, etc. interactively
6. The job is terminated

6.11.3.1 Terminating Interactive Jobs

When you run an interactive job, the `qsub` command does not terminate when the job is submitted. `qsub` remains running until one of the following:

- You `qdel` the job
- Someone else deletes the job
- You exit the shell
- The job is aborted
- You interrupt `qsub` with a SIGINT (the control-C key) before the scheduler starts the job.

Once the scheduler starts the job, SIGINT is ignored.

Under Linux, if you interrupt `qsub` before the job starts, `qsub` queries whether you want it to exit. If you respond "*yes*", `qsub` exits and the job is aborted. Under Windows, if you interrupt the job before it starts, the job is deleted, and the following messages are printed:

```
qsub: wait for job <job ID> interrupted by signal 2
<job ID> is being deleted
```

6.11.4 Interactive Jobs and Exit Codes

Under Windows, if you specify an exit code when you exit the interactive session, via "exit <exit code>", that exit code is used as the job's exit code. This exit code is visible in the output of the `tracejob` command.

Under Linux, you cannot provide an exit code for the interactive session.

6.11.5 Tracking Progress for Interactive Jobs

After you have submitted an interactive job, PBS prints the following message to the window where you submitted the job:

```
qsub: waiting for job <job ID> to start
```

When the job is started by the scheduler, PBS prints the following message to the submission window:

```
qsub: job <job ID> ready
```

When the interactive job finishes, PBS prints the following message to the submission window:

```
qsub: job <job ID> completed
```

6.11.6 Special Sequences for Interactive Jobs

Keyboard-generated interrupts are passed to the job. Lines entered that begin with the tilde ('~') character and contain special sequences are interpreted by `qsub` itself. The recognized special sequences are:

~.
: `qsub` terminates execution. The batch job is also terminated.

~susp
: Suspends the `qsub` program. "*susp*" is the suspend character, usually CTRL-Z.

~asusp
: Suspends the input half of `qsub` (terminal to job), but allows output to continue to be displayed. "*asusp*" is the auxiliary suspend character, usually control-Y.

6.11.7 Caveats and Restrictions for Interactive Jobs

- Make sure that your login file does not run processes in the background. See section 1.4.2.5, “Avoid Background Processes Inside Jobs”, on page 6.
- You cannot run an array job interactively.
- Interactive jobs are not rerunnable.
- You cannot use the `CLS` command in an interactive job. It will not clear the screen.
- After the scheduler has started the interactive job, SIGINT (Ctrl-C) is ignored.
- Under Linux, you cannot provide an exit code for the interactive session.
- When an interactive job finishes, staged files and *`stdout`* and/or *`stderr`* may not have been copied back yet.
- The submission host must accept incoming ephemeral ports

6.11.8 Errors and Logging

- If PBS cannot open a remote interactive shell to run an interactive job, PBS prints the following error message:
  `"qsub: failed to run remote interactive shell"`
- If IPC$ on the remote host cannot be connected, PBS prints the following message:
  `"Couldn't connect to host <hostname>"`
- If PBS is successful in connecting to the IPC$ at the execution host, but fails to execute the remote shell, PBS prints the following error message:
  `"Couldn't execute remote shell at host <hostname>"`

6.11.9 Receiving X Output from Interactive Linux Jobs

Under Linux, you can receive X output from an interactive job via the `qsub -X` option.

6.11.9.1 How to Receive X Output Under Linux

To receive X output, use `qsub -X -I`. For example:

```
qsub -I -X <return>
xterm <return>
```

Control is returned here when your X process terminates. You can background the process here, if you want to.

6.11.9.1.i Receiving X Output on Non-submission Host

You can view your X output on a host that is not the job submission host. For example, you submit a job from SubHost, and want to see the output on ViewHost. If you want to receive X output on a host that is not the submission host, for example ViewHost, do the following:

- Run an X server on ViewHost
- On ViewHost, log into SubHost using `ssh -X`
- In window logged into SubHost, run `qsub -I -X`

6.11.9.2 Requirements for Receiving X Output

- You must be running Linux.
- The job must be interactive: you must also specify `-I`.
- An X server must be running on the system where you want to see the X output.
- The DISPLAY variable in the job's submission environment must be set to the display where the X output is desired.
- Your administrator must configure MoM's PATH to include the `xauth` utility.

6.11.9.3 Viewing X Output Job Attributes

Each job has two read-only attributes containing X forwarding information. These are the following:

forward_x11_cookie
: This attribute contains the X authorization cookie.

forward_x11_port
: This attribute contains the number of the port being listened to by the port forwarder on the submission host.

You can view these attributes using `qstat -f <job ID>`.

6.11.9.4 Caveats and Advice for Receiving X Output

- This option is not available under Windows.
- If you use the `qsub -V` option, PBS will handle the DISPLAY variable correctly.
- If you use the `qsub -v DISPLAY` option, you will get an error.
- At most 25 concurrent X applications can run using the same job session.
- If you experience a problem with X when using `qsub –X –I`, use the following to create the correct `~/.Xauthority` file for `qsub` to use when establishing the X session:

  `ssh –X <hostname> server <-> <exec host(s)>`

6.11.9.5 X Forwarding Errors

- If the DISPLAY environment variable is pointing to a display number that is correctly formatted but incorrect, submitting an interactive X forwarding job results in the following error message:
  "cannot read data from 'xauth list <display number>', errno=<errno>"
- If the DISPLAY environment variable is pointing to an incorrectly formatted value, submitting an interactive X forwarding job results in the following error message:
  "qsub: Failed to get xauth data (check $DISPLAY variable)"
- If the X authority utility (xauth) is not found on the submission host, the following error message is displayed:
  "execution of xauth failed: sh: xauth: command not found"
- When the execution of the xauth utility results in an error, the error message displayed by the xauth utility is preceded by the following:
  "execution of xauth failed: "
- When the qsub –X option is used without -I, the following error message is displayed:
  "qsub: X11 forwarding possible only for Interactive Jobs"

6.11.10 Submitting Interactive GUI Jobs on Windows

You can run an interactive job that uses a GUI application. If the job executes on a host other than the one from which you submit the job, PBS uses a remote viewer or interactive shell to connect the GUI application to the remote host. Under Windows, PBS supports any GUI application, including Remote Viewer and X. If your job requires a GUI application or interactive shell, you must run it as an interactive job.

To run an interactive PBS job that launches a GUI application:

qsub -I -G -- <GUI application>

When the same host is used for submission and execution, the application is launched on the local console. No remote viewer client is launched.

When the submission and execution hosts are different, the GUI application is launched in the remote session using the specified remote viewer. The remote viewer client is launched.

To run X under Windows, do not use the -X option. This option is not available under Windows. Use -G.

To launch an interactive shell in a PBS job:

qsub -I -G

When the submission and execution host are the same, the interactive shell is launched on the local console. No remote viewer client is launched.

When the submission and execution hosts are different, the interactive shell is launched, and any GUI application launched through this shell is visible in the remote session using the configured remote viewer. The remote viewer client is launched.

Your interactive GUI job is finished or no longer running under the following circumstances:

- When the GUI application launched via qsub –I –G <GUI application> is closed
- When the interactive shell launched via qsub –I –G exits
- When the remote viewer is terminated, closed, or logged off, all applications started by the remote viewer are closed.
- When a GUI job is deleted via qdel, all the applications and tasks associated with the job are killed

See "-G [<path to GUI application or script>]" on page 223 of the PBS Professional Reference Guide.

6.12 Using Environment Variables

PBS provides your job with environment variables where the job runs. PBS takes some from your submission environment, and creates others. You can create environment variables for your job. The environment variables created by PBS begin with "*PBS_*". The environment variables that PBS takes from your submission (originating) environment begin with "*PBS_O_*".

For example, here are a few of the environment variables that accompany a job, with typical values:

```
PBS_O_HOME=/u/user1
PBS_O_LOGNAME=user1
PBS_O_PATH=/usr/bin:/usr/local/bin:/bin
PBS_O_SHELL=/bin/tcsh
PBS_O_HOST=host1
PBS_O_WORKDIR=/u/user1
PBS_JOBID=16386.server1
```

For a complete list of PBS environment variables, see "PBS Environment Variables" on page 397 of the PBS Professional Reference Guide.

6.12.1 Exporting All Environment Variables

The "`-V`" option declares that all environment variables in the `qsub` command's environment are to be exported to the batch job.

```
qsub -V my_job
#PBS -V
```

6.12.2 Exporting Specific Environment Variables

The "`-v <variable list>`" option to `qsub` allows you to specify additional environment variables to be exported to the job. *variable list* names environment variables from the `qsub` command environment which are made available to the job when it executes. These variables and their values are passed to the job. These variables are added to those already automatically exported. Format: comma-separated list of strings in the form:

-*v* <*variable*>

or

-*v* <*variable*>=<*value*>

If a <*variable*>=<*value*> pair contains any commas, the value must be enclosed in single or double quotes, and the <*variable*>=<*value*> pair must be enclosed in the kind of quotes not used to enclose the value. For example:

```
qsub -v DISPLAY,myvariable=32 my_job
qsub -v "var1='A,B,C,D'" job.sh
qsub -v a=10, "var2='A,B'", c=20, HOME=/home/zzz job.sh
```

6.12.3 Caveat for Environment Variables and Shell Functions

Make sure that no exported shell function you want to forward has the same name as an environment variable. The shell function will not be visible in the environment.

6.12.4 Forwarding Exported Shell Functions

You can forward exported shell functions using either `qsub -V` or `qsub -v <function name>`. You can also put these functions in your `.profile` or `.login` on the execution host(s).

If you use `-v` or `-V`, make sure that there is no environment variable with the same name as any exported shell functions you want to forward; otherwise, the shell function will not be visible in the environment.

6.13 Specifying Which Jobs to Preempt

You can specify which groups of jobs your job is allowed to preempt in order to run. You can specify all the jobs in one or more queues, and all jobs that request particular resources, by listing them in the preempt_targets resource.

Syntax:

...-l preempt_targets="queue=<queue name>[,queue=<queue name>],
Resource_List.<resource>=<value>[,Resource_List.<resource>=<value>]"

For example, to specify that your job can preempt jobs in the queue named QueueA and/or jobs that requested arch=linux:

```
...-l preempt_targets="queue=QueueA,Resource_List.arch=linux"
```

You can prevent a job from preempting any other job in the complex by setting its preemption_targets to the keyword "None" (case-insensitive).

Make the preempt_targets resource specification last or use another -l specification for subsequent resource specifications. Otherwise, subsequent resource specifications will look to PBS like additions to preempt_targets.

6.14 Releasing Unneeded Vnodes from Your Job

If you want to prevent unnecessary resource usage, you can release unneeded sister hosts or vnodes (not the primary execution host or its vnodes) from your job. You can use the `pbs_release_nodes` command or the release_nodes_on_stageout job attribute:

- You can use the `pbs_release_nodes` command either at the command line or in your job script to release sister hosts or vnodes when the command is issued. You can use this command to release specific vnodes that are not on the primary execution host, or all vnodes that are not on the primary execution host. You can also use it to release all hosts or vnodes except for what you specify, which can be either a count of hosts to keep, or a select specification describing the vnodes to keep. You cannot use the command to release vnodes on the primary execution host. See "pbs_release_nodes" on page 92 of the PBS Professional Reference Guide.
- You can set the job's release_nodes_on_stageout attribute to *True* so that PBS releases all of the job's vnodes that are not on the primary execution host when stageout begins. You must set the job's stageout attribute as well. See "Job Attributes" on page 327 of the PBS Professional Reference Guide.

6.14.1 Caveats and Restrictions for Releasing Vnodes

- You must specify a stageout parameter in order to be able to release vnodes on stageout. If you do not specify stageout, release_nodes_on_stageout has no effect.
- You can release only vnodes that are not on the primary execution host. You cannot release vnodes on the primary execution host.
- The job must be running (in the *R* state).
- The `pbs_release_nodes` command is not supported on vnodes tied to Cray X* series systems (vnodes whose vntype has the "cray_" prefix).
- If cgroups support is enabled, and `pbs_release_nodes` is called to release some but not all the vnodes managed by a MoM, resources on those vnodes are released.
- If a vnode on a multi-vnode host is assigned exclusively to a job, and the vnode is released, the job will show that the vnode is released, but the vnode will still show as assigned to the job in `pbsnodes -av` until the other vnodes on that host have been released. If a vnode on a multi-vnode machine is not assigned exclusively to a job, and the vnode is released, it shows as released whether or not the other vnodes on that host are released.
- If you specify release of a vnode on which a job process is running, that process is terminated when the vnode is released.

6.14.2 What Happens When You Release Vnodes

After you release a job's vnode:

- The job's $PBS_NODEFILE no longer lists the released vnode
- The server continues to hold on to the job until receiving confirmation that the job has been cleaned up from the vnode
- The vnode reports to the primary execution host MoM its resources_used* values for the job as the final action. The released vnode no longer updates the resources_used values for the job since it's no longer part of the job. But the primary execution host holds onto the data, and adds the data during final aggregation of resources_used values when job exits
- After every successful call to `pbs_release_nodes`, `qstat` shows updated values for the job's exec_host, exec_vnode, and Resource_List attributes

When releasing vnodes, if all vnodes assigned to a job managed by the same MoM have been released, the job is completely removed from that MoM's host. This results in the following:

- The execjob_epilogue hook script (if it exists) runs
- Job processes are killed on that host
- Any job-specific specific files including job temporary directories are removed

If one or more, but not all, the vnodes from an execution host assigned to a job are released, the job is not removed from that host yet. If those released vnodes have been configured to be shared, they can be reassigned to other jobs.

6.14.3 Examples of Releasing Unneeded Vnodes From Job

Example 6-4: Submit a job that will release its non-primary-execution-host vnodes on stageout:

```
% qsub -W stageout=my_stageout@executionhost2:my_stageout.out -W release_nodes_on_stageout=true
  job.scr
```

Example 6-5: Release particular vnodes from a job:

Syntax: *pbs_release_nodes [-j <job ID>] <vnode name> [<vnode name>] ...]*

```
% qsub job.scr
241.myserverhost
% qstat  241 | grep "exec|Resource_List|select"
exec_host = executionhost1[0]/0*0+executionhost2/0*0+executionhost3/0*2
exec_vnode =
    (executionhost1[0]:mem=1048576kb:ncpus=1+executionhost1[1]:mem=1048576kb:ncpus=1+executionho
    st1[2]:ncpus=1)+(executionhost2:mem=104
8576kb:ncpus=1+executionhost2[0]:mem=1048576k:ncpus=1+executionhost2[1]:ncpus=1)+(executionhost3
    :ncpus=2:mem=2097152kb)
Resource_List.mem = 6gb
Resource_List.ncpus = 8
Resource_List.nodect = 3
Resource_List.place = scatter
Resource_List.select = ncpus=3:mem=2gb+ncpus=3:mem=2gb+ncpus=2:mem=2gb
schedselect = 1:ncpus=3:mem=2gb+1:ncpus=3:mem=2gb+1:ncpus=2:mem=2gb
% pbs_release_nodes -j 241 executionhost2[1] executionhost3
% qstat  241 | grep "exec|Resource_List|select"
exec_host = executionhost1[0]/0*0+executionhost2/0*0  (no executionhost3; all assigned vnodes in
    executionhost3 have been released)
exec_vnode =
    (executionhost1[0]:mem=1048576kb:ncpus=1+executionhost1[1]:mem=1048576kb:ncpus=1+executionho
    st1[2]:ncpus=1)+(executionhost2:mem=1048576kb:ncpus=1+executionhost2[0]:mem=1048576kb:ncpus=
    1)  (executionhost2[1] and executionhost3 no longer appear)
Resource_List.mem = 4194304kb  (reduced by 2gb from executionhost3)
Resource_List.ncpus = 5     (reduced by 3 CPUs, 1 from executionhost2[1] and 2 from executionhost3)
Resource_List.nodect = 2     (reduced by 1 chunk; when executionhost3 was released, its entire chunk assignment
    disappeared)
Resource_List.place = scatter
schedselect = 1:mem=2097152kb:ncpus=3+1:mem=2097152kb:ncpus=2
```

Example 6-6: Release all vnodes not on the primary execution host:

Syntax: *pbs_release_nodes [-j <job ID>] -a*

```
% pbs_release_nodes -j 241 -a
% qstat -f 241
exec_host = executionhost1[0]/0*0
exec_vnode =
    (executionhost1[0]:mem=1048576kb:ncpus=1)+executionhost1[1]:mem=1048576kb:ncpus=1+executionh
    ost1[2]:ncpus=1)
Resource_List.mem = 2097152kb
Resource_List.ncpus =  3
Resource_List.nodect = 1
Resource_List.place = scatter
schedselect = 1:mem=2097152kb:ncpus=3
```

Example 6-7: Release all sister hosts except for 4:

```
% pbs_release_nodes -k 4
```

Example 6-8: Release all sister vnodes except for 8 of those marked with "bigmem":

```
% pbs_release_nodes -k select=8:bigmem=true
```

Example 6-9: Sister vnodes are no longer listed in $PBS_NODEFILE after they are released:

```
% qsub -l select=2:ncpus=1:mem=1gb -l place=scatter -I
qsub: waiting for job 247.executionhost1.example.com to start
qsub: job 247.executionhost1.example.com ready
% cat $PBS_NODEFILE
executionhost1.example.com
executionhost2.example.com
% pbs_release_nodes -j 247 executionhost2
% cat $PBS_NODEFILE
executionhost1.example.com
```

6.15 Running Your Job in a Container

PBS supports running multi-vnode, multi-host, and interactive jobs in Docker and Singularity containers.

You can pull from a public registry, or you can pull from a private registry as long as you can log into it.

If you do not specify a script, for example "`qsub -l container_image=hello-world`", `qsub` asks you interactively for a script.

If you supply a script to `qsub`, PBS runs the script inside the specified container.

For a multi-host job, you can use any version of OpenMPI with containers.

PBS runs an infinite-duration sleep command in the container to keep the container alive.

6.15.1 Requesting a Container Engine

You can specify a container engine by requesting a resource whose value is set to that engine, or you can use the default by not requesting one. You can request only one container engine per job, even though this resource is requested at the host level. You must request the same container engine for all chunks. Ask your administrator for the name of the resource listing available container engines, or find it using `pbsnodes` (look for container engine names). We recommend that this resource is named "container engine".

qsub ... -l select=ncpus=...:<container engine resource>=<container engine>

6.15.2 Requesting a Container Image

You request a container image for your job via `-l container_image=<container image>` or by setting the CONTAINER_IMAGE environment variable to the name of the image and passing the environment variable with the job:

qsub ... -l container_image=<container image> ...

or

qsub ... -v CONTAINER_IMAGE=<name of container image> ...

6.15.2.1 Specifying a Registry

If you don't specify a registry, PBS uses a default, set by your administrator. You can specify the registry in the container image.

Example 6-10: Specifying the registry (and namespace) in the container image:

```
qsub -v CONTAINER_IMAGE=pbsprohub.local/pbsuser/test-image
```

6.15.2.2 Pulling from a Private Registry

To pull from a private registry, PBS uses a credential file to log into the registry. This file is in JSON format.

6.15.2.2.i Registry Credential Filename

The credential filename has this format:

<job owner>/.container/tokens.json

6.15.2.2.ii Registry Credential File Format

The file contents have this format:

```
{
   "registry1 <URL>/<endpoint>": {
      "user_id" : "<user ID>" , "passwd" : "<generated OAUTH token/password>"
   },

   "registry2 <URL>/<endpoint>": {
      "user_id" : "<user ID>" , "passwd" : "<generated OAUTH token/password>"
   }
}
```

6.15.2.2.iii Registry Credential File Default Values

registry: default registry (first element in the allowed_registries parameter)

user_id: job owner; if this is empty, PBS tries instead with the job owner ID

passwd: no password

6.15.2.2.iv Registry Credential File Location

The registry credential file *base path* is the path to where registry credential files are stored, up to but not including `<job owner>/.container/tokens.json`. The default base path to registry credential files is `/home`. Your administrator can configure the base path to where registry credential files are stored.

Example 6-11: The base path is "/container/creds/", and your job owner is User1. The full path to the JSON file is:

```
/container/creds/User1/.container/tokens.json
```

6.15.2.3 Specifying Image Namespace

PBS uses the registry's default namespace for container images unless you specify otherwise. If the image you want is in a non-default namespace, specify the namespace with the image name.

Example 6-12: To request the Docker container engine and an image named "centos", using the "MyImages" namespace:

```
qsub -l select=1:ncpus=1:container_engine=docker -lcontainer_image="MyImages/centos"  --
   /bin/sleep 500
```

Example 6-13: To request the Docker container engine and an image named "centos", using the default namespace:

```
qsub -l select=1:ncpus=1:container_engine=docker -lcontainer_image="centos"  -- /bin/sleep 500
```

6.15.3 Specifying Ports with Docker Containers

For single-vnode jobs in Docker containers, you can request ports for applications. PBS maps requested ports to available ports on the host and returns the mapping. You request ports by listing comma-separated port numbers in the container_ports job resource. Lists of port numbers must be enclosed in single quotes. PBS sets the job's resources_used.container_ports value to comma-separated *<container port>:<host port>* pairs. For example, your job can request specific ports:

```
qsub -l container_ports="'2324,8989'" ...
```

PBS returns the port mapping in the job's resources_used.container_ports resource:

```
resources_used.container_ports = 2324:8080,8989:32771
```

6.15.4 Specifying Additional Arguments to Container Engine

You can specify additional arguments to the container engine via the PBS_CONTAINER_ARGS environment variable, which is a semicolon-separated list. For example, to specify `--shm-size` to be 1GB and `--tmpfs` to be "/run:rw,noexec,nosuid,size=65536k":

```
export PBS_CONTAINER_ARGS="--shm-size=1GB";"--tmpfs /run:rw,noexec,nosuid,size=65536k"
```

Your PBS administrator must whitelist any additional arguments before you use them in a job.

The `--env` and `--entrypoint` arguments to `docker run` are not supported.

6.15.5 Passing Environment Variables Into Containers

To pass environment variables directly to PBS, use `qsub -v <environment variable list>`. The `--env` argument is not supported for passing environment variables into containers.

6.15.6 Adding Job Owner to Secondary Groups in Docker Containers

Your administrator can configure PBS to add the job owner to secondary groups inside the container. These are the groups on the execution host where the job owner is already a member. This feature applies only to Docker containers, since Singularity automatically adds the job owner to all groups.

6.15.7 Running Single-vnode Single-host Jobs in Singularity Containers

In addition to using PBS to launch your containers, you can always run a single-vnode job in a single Singularity container by prepending your scripts, executables, or commands with the Singularity binary.

6.15.8 Specifying Shell in Container

You can run your default shell inside a container without taking any extra steps. To run a shell in a container using anything besides the default, you must specify the shell using the `-S` option to `qsub`. Make sure the selected shell is available inside the container.

6.15.9 Caveats and Restrictions

- You cannot use old-style resource requests such as `-lncpus` with containers.
- Any entry point in a container is disabled. If you want to run the equivalent of an entry point command, you must include the complete command with its arguments on the command line.
- Mounting some directories or files in your container may be restricted. Ask your administrator for details.

6.15.10 Restrictions and Caveats for Cloud Bursting with PBS

- Cloud bursting is supported only on Linux.
- Reservations are not supported on cloud nodes.

6.16 Allowing Your Job to Tolerate Vnode Failures

You can allow your job to tolerate vnode failures if your administrator has configured PBS to do so. PBS lets you allocate extra vnodes to a job so that the job can successfully start and run even if some vnodes fail. PBS can allocate the extra vnodes only for startup, or for the life of the job. Later, for jobs where the extra vnodes are needed only for reliable startup, PBS can trim the allocated vnodes back to just what the job will use to run, releasing the unneeded vnodes for other jobs.

To allow your job to tolerate vnode failures during startup only, set the job's tolerate_node_failures attribute to "*start*".

To allow your job to tolerate vnode failures during the life of the job, set the job's tolerate_node_failures attribute to "*all*".

Examples of setting this attribute:

- Via qsub:

```
qsub -W tolerate_node_failures="all" <job script>
```

- Via qalter:

```
qalter -W tolerate_node_failures="job_start" <job ID>
```

7 Reserving Resources

In this chapter we go over job reservations only (advance, standing, and job-specific reservations); maintenance reservations are covered in "Reservations" on page 195 in the PBS Professional Administrator's Guide.

7.1 Glossary

Advance reservation

A reservation for a set of resources for a specified time. The reservation is available only to the creator of the reservation and any users or groups specified by the creator.

Degraded reservation

A job-specific or advance reservation for which one or more associated vnodes are unavailable.

A standing reservation for which one or more vnodes associated with any occurrence are unavailable.

Job-specific reservation

A reservation created for a specific job, for the same resources that the job requested.

Job-specific ASAP reservation

Reservation created for a specific queued job, for the same resources the job requests. PBS schedules the reservation to run as soon as possible, and PBS moves the job into the reservation. Created when you use `pbs_rsub -Wqmove=<job ID>` on a queued job.

Job-specific now reservation

Reservation created for a specific running job. PBS immediately creates a job-specific now reservation on the same resources as the job is using, and moves the job into the reservation. The reservation is created and starts running immediately when you use `pbs_rsub --job <job ID>` on a running job.

Job-specific start reservation

Reservation created for a specific job, for the same resources the job requests. PBS starts the job according to scheduling policy. When the job starts, PBS creates and starts the reservation, and PBS moves the job into the reservation. Created when you use `qsub -Wcreate_resv_from_job=true` to submit a job or when you `qalter` a job to set the job's create_resv_from_job attribute to *True*.

Occurrence of a standing reservation

An instance of the standing reservation.

An occurrence of a standing reservation behaves like an advance reservation, with the following exceptions:

- while a job can be submitted to a specific advance reservation, it can only be submitted to the standing reservation as a whole, not to a specific occurrence. You can only specify *when* the job is eligible to run. See"qsub" on page 216 of the PBS Professional Reference Guide.
- when an advance reservation ends, it and all of its jobs, running or queued, are deleted, but when an occurrence ends, only its running jobs are deleted.

Each occurrence of a standing reservation has reserved resources which satisfy the resource request, but each occurrence may have its resources drawn from a different source. A query for the resources assigned to a standing reservation will return the resources assigned to the soonest occurrence, shown in the resv_nodes attribute reported by `pbs_rstat`.

Soonest occurrence of a standing reservation

The occurrence which is currently active, or if none is active, then it is the next occurrence.

Standing reservation

An advance reservation which recurs at specified times. For example, you can reserve 8 CPUs and 10GB every Wednesday and Thursday from 5pm to 8pm, for the next three months.

7.2 Quick Explanation of Reservations for Jobs

You can reserve resources to be used later by jobs, or you can create a reservation using the resources requested by a specific job, and move the job into that reservation.

You create an advance or standing reservation, then submit jobs to the reservation. An **advance reservation** reserves specific resources for a specific time period, and a **standing reservation** does the same thing, but for a repeating sequence of time periods.

PBS creates **job-specific reservations** by reserving the same resources that a queued job requests, or a running job is using, then moving the job into the reservation's queue.

- PBS creates Job-specific Start Reservations for specific queued jobs whose create_resv_from_job attribute is *True*. When the job runs, PBS creates and starts the reservation, and PBS moves the job into the reservation. This reservation allows you to re-run the job later without having to wait for it to be scheduled again. You can set this attribute at submission using `qsub -Wcreate_resv_from_job=true`.
- PBS creates Job-specific ASAP Reservations for specific queued jobs when you use `pbs_rsub -Wqmove=<job ID>` on those jobs. PBS creates the reservation and moves the job into the reservation, and the reservation is scheduled to run as soon as possible.
- PBS creates Job-specific Now Reservations for specific running jobs when you use `pbs_rsub --job <job ID>` on them. PBS immediately creates a reservation, starts it, and moves the job into the reservation. This reservation allows you to re-run the job without having to wait for it to be scheduled again.

7.3 Prerequisites for Reserving Resources

The time for which a reservation is requested is in the time zone at the submission host.

You must set the submission host's `PBS_TZID` environment variable. The format for `PBS_TZID` is a timezone location. Example: `America/Los_Angeles, America/Detroit, Europe/Berlin, Asia/Kolkata`. See section 1.4.4, “Setting Time Zone for Submission Host”, on page 9.

7.4 Advance and Standing Reservations

7.4.1 Introduction to Creating and Using Advance and Standing Reservations

You can create both advance and standing reservations using the `pbs_rsub` command. PBS either confirms that the reservation can be made, or rejects the request. Once the reservation is confirmed, PBS creates a queue for the reservation's jobs. Jobs are then submitted to this queue.

When a reservation is confirmed, it means that the reservation will not conflict with currently running jobs, other confirmed reservations, or dedicated time, and that the requested resources are available for the reservation. A reservation request that fails these tests is rejected. All occurrences of a standing reservation must be acceptable in order for the standing reservation to be confirmed.

The pbs_rsub command returns a *reservation ID*, which is the reservation name. For an advance reservation, this reservation ID has the format:

R<sequence number>.<server name>

For a standing reservation, this reservation ID refers to the entire series, and has the format:

S<sequence number>.<server name>

You specify the resources for a reservation using the same syntax as for a job. Jobs in reservations are placed the same way non-reservation jobs are placed in placement sets.

The time for which a reservation is requested is in the time zone at the submission host.

The pbs_rsub command returns a reservation ID string, and the current status of the reservation.

You can create an advance or standing reservation so that if the reservation sits idle, it is automatically deleted after the amount of time you specify. For a standing reservation, this applies to each occurrence separately. If one occurrence of a standing reservation is deleted, the next occurrence still starts at its designated time. To have your reservation be deleted automatically, use pbs_rsub -Wdelete_idle_time=<allowed idle time> and specify the number of seconds as an integer, or the duration as *HH:MM:SS*.

For the options to the pbs_rsub command, see "pbs_rsub" on page 96 of the PBS Professional Reference Guide.

7.4.2 Creating Advance Reservations

You create an advance reservation using the pbs_rsub command. PBS must be able to calculate the start and end times of the reservation, so you must specify two of the following three options:

D Duration

E End time

R Start time

7.4.2.1 Setting Time Zone for Advance Reservations

If you need the time zone for your advance reservation to be UTC, set this when you create the reservation:

```
TZ=UTC pbs_rsub -R...
```

7.4.2.2 Examples of Creating Advance Reservations

The following example shows the creation of an advance reservation asking for 1 vnode, 30 minutes of wall-clock time, and a start time of 11:30. Since an end time is not specified, PBS will calculate the end time based on the reservation start time and duration.

```
pbs_rsub -R 1130 -D 00:30:00
```

PBS returns the reservation ID:

```
R226.south UNCONFIRMED
```

The following example shows an advance reservation for 2 CPUs from 8:00 p.m. to 10:00 p.m.:

```
pbs_rsub -R 2000.00 -E 2200.00 -l select=1:ncpus=2
```

PBS returns the reservation ID:

```
R332.south UNCONFIRMED
```

7.4.3 Creating Standing Reservations

You create standing reservations using the pbs_rsub command. You **must** specify a start and end date when creating a standing reservation. The recurring nature of the reservation is specified using the -r option to pbs_rsub. The -r option takes the recurrence_rule argument, which specifies the standing reservation's occurrences. The recurrence rule uses iCalendar syntax, and uses a subset of the parameters described in RFC 2445.

The recurrence rule can take two forms:

"FREQ=<freq spec>;COUNT=<count spec>;<interval spec>"

In this form, you specify how often there will be occurrences, how many there will be, and which days and/or hours apply.

"FREQ=<freq spec>;UNTIL=<until spec>;<interval spec>"

Do not include any spaces in your recurrence rule.

In this form, you specify how often there will be occurrences, when the occurrences will end, and which days and/or hours apply.

freq spec

This is the frequency with which the reservation repeats. Valid values are *WEEKLY|DAILY|HOURLY*

When using a *freq spec* of *WEEKLY*, you may use an *interval spec* of *BYDAY* and/or *BYHOUR*. When using a *freq spec* of *DAILY*, you may use an *interval spec* of *BYHOUR*. When using a *freq spec* of HOURLY, do not use an *interval spec*.

count spec

The exact number of occurrences. Number up to 4 digits in length. Format: integer.

interval spec

Specifies the interval at which there will be occurrences. Can be one or both of *BYDAY=<days>* or *BYHOUR=<hours>*. Valid values are *BYDAY = MO|TU|WE|TH|FR|SA|SU* and *BYHOUR = 0|1|2|...|23*. When using both, separate them with a semicolon. Separate days or hours with a comma.

For example, to specify that there will be recurrences on Tuesdays and Wednesdays, at 9 a.m. and 11 a.m., use BYDAY=TU,WE;BYHOUR=9,11

BYDAY should be used with *FREQ=WEEKLY*. *BYHOUR* should be used with *FREQ=DAILY* or *FREQ=WEEKLY*.

until spec

Occurrences will start up to but not after this date and time. This means that if occurrences last for an hour, and normally start at 9 a.m., then a time of 9:05 a.m on the day specified in the *until spec* means that an occurrence will start on that day.

Format: *YYYYMMDD[THHMMSS]*

Note that the year-month-day section is separated from the hour-minute-second section by a capital *T*.

Default: 3 years from time of reservation creation.

7.4.3.1 Setting Reservation Start Time and Duration

In a standing reservation, the arguments to the -R and -E options to pbs_rsub can provide more information than they do in an advance reservation. In an advance reservation, they provide the start and end time of the reservation. In a standing reservation, they can provide the start and end time, but they can also be used to compute the duration and the offset from the interval start.

The difference between the values of the arguments for -R and -E is the duration of the reservation. For example, if you specify

```
-R 0930 -E 1145
```

the duration of your reservation will be two hours and fifteen minutes. If you specify

```
-R 150800 -E 170830
```

the duration of your reservation will be two days plus 30 minutes.

The *interval spec* can be used to specify the day or the hour at which the interval starts. If you specify

```
-R 0915 -E 0945 ... BYHOUR=9,10
```

the duration is 30 minutes, and the offset is 15 minutes from the start of the interval. The interval start is at 9 and again at 10. Your reservation will run from 9:15 to 9:45, and again at 10:15 and 10:45. Similarly, if you specify

```
-R 0800 -E -1000 ... BYDAY=WE,TH
```

the duration is two hours and the offset is 8 hours from the start of the interval. Your reservation will run Wednesday from 8 to 10, and again on Thursday from 8 to 10.

Elements specified in the recurrence rule override those specified in the arguments to the -R and -E options. Therefore if you specify

```
-R 0730 -E 0830 ... BYHOUR=9
```

the duration is one hour, but the hour element (9:00) in the recurrence rule has overridden the hour element specified in the argument to -R (7:00). The offset is still 30 minutes after the interval start. Your reservation will run from 9:30 to 10:30. Similarly, if the 16th is a Monday, and you specify

```
-R 160800 -E 170900 ... BYDAY=TU;BYHOUR=11
```

the duration 25 hours, but both the day and the hour elements have been overridden. Your reservation will run on Tuesday at 11, for 25 hours, ending Wednesday at 12. However, if you specify

```
-R 160810 -E 170910 ... BYDAY=TU;BYHOUR=11
```

the duration is 25 hours, and the offset from the interval start is 10 minutes. Your reservation will run on Tuesday at 11:10, for 25 hours, ending Wednesday at 12:10. The minutes in the offset weren't overridden by anything in the recurrence rule.

The values specified for the arguments to the -R and -E options can be used to set the start and end times in a standing reservation, just as they are in an advance reservation. To do this, don't override their elements inside the recurrence rule. If you specify

```
-R 0930 -E 1030 ... BYDAY=MO,TU
```

you haven't overridden the hour or minute elements. Your reservation will run Monday and Tuesday, from 9:30 to 10:30.

7.4.3.2 Requirements for Creating Standing Reservations

- You must specify a start and end date.
- You must set the submission host's PBS_TZID environment variable. The format for PBS_TZID is a timezone location. Example: America/Los_Angeles, America/Detroit, Europe/Berlin, Asia/Calcutta. See section 1.4.4, “Setting Time Zone for Submission Host”, on page 9.
- The recurrence rule must be one unbroken line.
- The recurrence rule must be enclosed in double quotes.
- Vnodes that have been configured to accept jobs only from a specific queue (vnode-queue restrictions) cannot be used for advance or standing reservations. See your PBS administrator to determine whether some vnodes have been configured to accept jobs only from specific queues.
- Make sure that there are no spaces in your recurrence rule.

7.4.3.3 Examples of Creating Standing Reservations

For a reservation that runs every day from 8am to 10am, for a total of 10 occurrences:

```
pbs_rsub -R 0800 -E 1000 - r"FREQ=DAILY;COUNT=10"
```

Every weekday from 6am to 6pm until December 10, 2008:

```
pbs_rsub -R 0600 -E 1800 -r "FREQ=WEEKLY;BYDAY=MO,TU,WE,TH,FR;UNTIL=20081210"
```

Every week from 3pm to 5pm on Monday, Wednesday, and Friday, for 9 occurrences, i.e., for three weeks:

```
pbs_rsub -R 1500 -E 1700 -r "FREQ=WEEKLY;BYDAY=MO,WE,FR;COUNT=9"
```

7.5 Job-specific Reservations

7.5.1 Job-specific Start Reservations

PBS runs the job normally, and when the job starts, PBS creates and starts a *job-specific start reservation* and moves the job into the reservation. PBS creates the reservation using the same resources that are being used by the job. The reservation holds the resources needed for the job in case the job fails and needs to be re-submitted, allowing it to run again without having to wait to be scheduled. The reservation starts when the job starts and has the same end time as the job.

If you have a queued job that you think is likely to fail and need to be corrected and re-submitted, you can create a job-specific *start reservation*. When you submit the job, set its create_resv_from_job attribute to *True* using the `-W` option to qsub:

qsub ... -Wcreate_resv_from_job=true

For example, to create a job-specific start reservation for the job whose script is named myscript.sh:

```
qsub -Wcreate_resv_from_job=true myscript.sh
```

You can also `qalter` a queued job to set this attribute:

qalter -Wcreate_resv_from_job=true <job ID>

For example, to create a start reservation when job 1234.myserver starts:

```
qalter -Wcreate_resv_from_job=true 1234.myserver
```

A job-specific start reservation ID has the format:

R<sequence number>.<server name>

PBS sets the start reservation's reserve_job attribute to the ID of the job from which the reservation was created, sets the reservation's Reserve_Owner attribute to the value of the job's Job_Owner attribute, sets the reservation's resv_nodes attribute to the jobs's exec_vnode attribute, sets the reservation's resources to the job's schedselect attribute, and sets the reservation's Resource_List attribute to the job's Resource_List attribute.

The start reservation's duration and start time are the same as the job's walltime and start time. If the job is peer scheduled, the now reservation is created in the pulling complex.

The start reservation is created when the job begins execution. You can set the create_resv_from_job attribute to *True* at any time, but this is only effective if you do it before the job starts. If your job has started running and you want to create a job-specific reservation for it, create a job-specific now reservation; see section 7.5.3, “Job-specific Now Reservations”, on page 143.

Can be used only with queued jobs.

Cannot be used with job arrays, jobs being submitted to other reservations, or other users' jobs.

7.5.2 Job-specific ASAP Reservations

PBS schedules a *job-specific ASAP reservation* to start as soon as possible. PBS creates a *job-specific ASAP reservation* using the resources requested by a specific queued job, and moves the job into the reservation.

Other jobs can also be moved into that queue via `qmove` or submitted to that queue via `qsub`.

To create an ASAP reservation:

pbs_rsub -W qmove=<job ID>

For example, to create an ASAP reservation for job 1234.myserver:

```
pbs_rsub -W qmove="1234.myserver"
```

A job-specific ASAP reservation ID has the format:

R<sequence number>.<server name>

The `-R` and `-E` options to `pbs_rsub` are disabled when using the `-W qmove` option.

Cannot be used on job arrays.

For more information, see "pbs_rsub" on page 96 of the PBS Professional Reference Guide.

We recommend using ASAP reservations only for sites that set job walltime. A job's default walltime is 5 years. Therefore an ASAP reservation's start time can be 5 years later, or more, if all the jobs in the system have the default walltime.

The delete_idle_time attribute for an ASAP reservation has a default value of 10 minutes.

7.5.3 Job-specific Now Reservations

PBS creates and starts a *job-specific now reservation* on the same resources used by a running job, and moves the running job into the reservation. The reservation holds the resources needed for the job in case the job fails and needs to be re-submitted, allowing it to run again without having to wait to be scheduled.

If you realize that a running job needs modification and re-submitting, and you don't want to have to wait until the scheduler finds a slot, you can create a now reservation. Later, you can submit a modified version of the job into the reservation:

pbs_rsub --job <job ID>

For example, to create a now reservation for job 1234.myserver while it's running:

```
pbs_rsub --job 1234.myserver
```

A job-specific now reservation ID has the format:

R<sequence number>.<server name>

PBS sets the job's create_resv_from_job attribute to *True*, sets the now reservation's reserve_job attribute to the ID of the job from which the reservation was created, sets the reservation's Reserve_Owner attribute to the value of the job's Job_Owner attribute, sets the reservation's resv_nodes attribute to the jobs's exec_vnode attribute, sets the reservation's resources to the job's schedselect attribute, and sets the reservation's Resource_List attribute to the job's Resource_List attribute.

The now reservation's duration and start time are the same as the job's walltime and start time. If the job is peer scheduled, the now reservation is created in the pulling complex.

Can be used on running jobs only (jobs in the *R* state, with substate *42*).

Cannot be used with job arrays, jobs already in reservations, or other users' jobs.

7.6 Getting Confirmation of a Reservation

By default the pbs_rsub command does not immediately notify you whether the reservation is confirmed or denied. Instead you receive email with this information. You can specify that the pbs_rsub command should wait for confirmation by using the -I *<block time>* option. The pbs_rsub command will wait up to *block time* seconds for the reservation to be confirmed or denied and then notify you of the outcome. If *block time* is negative and the reservation is not confirmed in that time, the reservation is automatically deleted.

To find out whether the reservation has been confirmed, use the pbs_rstat command. It will display the state of the reservation. CO and RESV_CONFIRMED indicate that it is confirmed. If the reservation does not appear in the output from pbs_rstat, that means that the reservation was denied.

To ensure that you receive mail about your reservations, set the reservation's Mail_Users attribute via the -M *<email address>* option to pbs_rsub. By default, you will get email when the reservation is terminated or confirmed. If you want to receive email about events other than those, set the reservation's Mail_Points attribute via the -m *<mail events>* option. For more information, see "pbs_rsub" on page 96 of the PBS Professional Reference Guide and "Reservation Attributes" on page 303 of the PBS Professional Reference Guide.

7.7 Modifying Reservations

You can use the pbs_ralter command to alter an existing reservation, whether it is an individual job-specific or advance reservation, or the next or current instance of a standing reservation. Syntax:

pbs_ralter [-D <duration>] [-E <end time>] [-G <auth group list>] [-I <block time>] [-l select=<select spec>] [-m <mail points>] [-M <mail list>] [-N <reservation name>] [-R <start time>] [-U <auth user list>] <reservation ID>

You can modify an advance or standing reservation so that if the reservation sits idle, it is automatically deleted after the amount of time you specify. For a standing reservation, this applies to each occurrence separately. If one occurrence of a standing reservation is deleted, the next occurrence still starts at its designated time. To have a reservation be deleted automatically, use pbs_ralter -Wdelete_idle_time=<allowed idle time> and specify the number of seconds as an integer, or the duration as *HH:MM:SS*. Note that you cannot change any other reservation attributes when you change this one.

You cannot change the start time of a reservation in which jobs are running.

When changing the select specification, the behavior depends on whether there are jobs running.

- If jobs are running in the reservation:
  - You cannot release chunks where reservation jobs are running
  - Vnodes where jobs are running cannot change, but everything else can
- If no jobs are running, the select specification can be changed completely

When requesting chunks, make sure each chunk request specifies chunks of a single type.

To find unused chunks in a running reservation, you can compare the reservation's resv_nodes attribute to the exec_vnode attribute of the jobs running in the reservation.

If the reservation has not started, modifying the select specification may result in moving the reservation to different vnodes.

After the change is requested, the change is either confirmed or denied. On denial of the change, the reservation is not deleted and is left as is, and the following message appears in the server's log:

```
Unable to alter reservation <reservation ID>
```

When a reservation is confirmed, the following message appears in the server's log:

```
Reservation alter successful for <reservation ID>
```

To find out whether or not the change was allowed:

- Use the `pbs_rstat` command: see whether you altered reservation attribute(s)
- Use the interactive option: check for confirmation after the blocking time has run out

If the reservation has not started and it cannot be confirmed on the same vnodes, PBS searches for another set of vnodes. See section 8.4, "Reservation Fault Tolerance", on page 401 of the PBS Professional Administrator's Guide.

You must be the reservation owner or the PBS Administrator to run this command.

For details, see "pbs_ralter" on page 85 of the PBS Professional Reference Guide.

7.7.0.0.i Examples of Modifying Reservations

Example 7-1: Grow a reservation:

Existing:

```
select=100:ncpus=20:mem=512gb
```

```
pbs_ralter -l select=150:ncpus=20:mem=512gb
```

Example 7-2: Grow and shrink a reservation:

Existing:

```
select=100:ncpus=20+10:ncpus=10:mem=512gb
```

```
pbs_ralter -l select=150:ncpus=20+5:ncpus=10:mem=512gb
```

Example 7-3: Grow a reservation, and get rid of a type of chunk:

Existing:

```
select=100:ncpus=20+10:ncpus=10:mem=512MB+15:ncpus=40
```

```
pbs_ralter -l select=150:ncpus=20+30:ncpus=40
```

Example 7-4: No running jobs; change select completely:

Existing:

```
select=100:ncpus=20+10:ncpus=10:mem=512GB
```

```
pbs_ralter -l select=150:ncpus=20:mem=1024GB+5:ncpus=15:mem=512GB
```

Example 7-5: Job is running on 50 vnodes of the first type of chunk; grow and shrink reservation:

Existing:

```
select=100:ncpus=20+50:ncpus=40
```

```
pbs_ralter -l select=50:ncpus=20+100:ncpus=40
```

Example 7-6: Negative example. With job running on 50 vnodes on the first type of chunk, we try to do an invalid alteration by trying to remove chunks from running jobs:

Existing:

```
select =100:ncpus=20+50:ncpus=40
```

```
pbs_ralter -l select=25:ncpus=20+100:ncpus=40
ALTER DENIED
```

7.8 Deleting Reservations

You can delete a reservation by using the `pbs_rdel` command. For a standing reservation, you can only delete the entire reservation, including all occurrences. When you delete a reservation, all of the jobs that have been submitted to the reservation are also deleted. A reservation can be deleted by its owner or by a PBS Operator or Manager. For example, to delete `S304.south`:

```
pbs_rdel S304.south
```

or

```
pbs_rdel S304
```

You can create a reservation so that if the reservation sits idle, it is automatically deleted after the amount of time you specify. For a standing reservation, this applies to each occurrence separately. If one occurrence of a standing reservation is deleted, the next occurrence still starts at its designated time. To have your reservation be deleted automatically, use `pbs_rsub -Wdelete_idle_time=<allowed idle time>` and specify the number of seconds as an integer, or the duration as *HH:MM:SS*.

7.9 Viewing the Status of a Reservation

The following table shows the list of possible states for a reservation. The states that you will usually see are `CO, UN, BD`, and `RN`, although a reservation usually remains unconfirmed for too short a time to see that state. See "Reservation States" on page 367 of the PBS Professional Reference Guide.

To view the status of a reservation, use the `pbs_rstat` command. It will display the status of all reservations at the PBS server. For a standing reservation, the `pbs_rstat` command will display the status of the soonest occurrence. Duration is shown in seconds. The `pbs_rstat` command will not display a custom resource which has been created to be invisible. See section 4.3.8, "Caveats and Restrictions on Requesting Resources", on page 59. This command has three options:

Table 7-1: Options to `pbs_rstat` Command

Option	Meaning	Description
`B`	Brief	Lists only the names of the reservations
`S`	Short	Lists in table format the name, queue name, owner, state, and start, duration and end times of each reservation
`F`	Full	Lists the name and all non-default-value attributes for each reservation.
<none>	Default	Default is `S` option

The full listing for a standing reservation is identical to the listing for an advance reservation, with the following additions:

- A line that specifies the recurrence rule:
  `reserve_rrule = FREQ=WEEKLY;BYDAY=MO;COUNT=5`
- An entry for the vnodes reserved for the soonest occurrence of the standing reservation. This entry also appears for an advance reservation, but will be different for each occurrence:
  `resv_nodes=(<vnode name>:...)`
- A line that specifies the total number of occurrences of the standing reservation:
  `reserve_count = 5`
- The index of the soonest occurrence:
  `reserve_index = 1`
- The timezone at the site of submission of the reservation is appended to the reservation's Variable_List attribute. For example, in California:
  `Variable_List=<other variables>PBS_TZID=America/Los_Angeles`

To get the status of a reservation at a server other than the default server, set the `PBS_SERVER` environment variable to the name of the server you wish to query, then use the `pbs_rstat` command. Your PBS commands will treat the new server as the default server, so you may wish to unset this environment variable when you are finished.

You can also get information about the reservation's queue by using the `qstat` command. See "qstat" on page 200 of the PBS Professional Reference Guide .

7.9.1 Examples of Viewing Reservation Status Using `pbs_rstat`

In our example, we have one advance reservation and one standing reservation. The advance reservation is for today, for two hours, starting at noon. The standing reservation is for every Thursday, for one hour, starting at 3:00 p.m. Today is Monday, April 28th, and the time is 1:00, so the advance reservation is running, and the soonest occurrence of the standing reservation is Thursday, May 1, at 3:00 p.m.

Example brief output:

```
pbs_rstat -B
Name: R302.south
Name: S304.south
```

Example short output:

```
pbs_rstat -S

Name      Queue User State Start / Duration / End
---------------------------------------------------------
R302.south R302 user1 RN Today 12:00 / 7200/  Today 14:00
S304.south S304 user1 CO May 1 2008 15:00/3600/May 1 2008 16:00
```

Example full output:

```
pbs_rstat -F
Name: R302.south
Reserve_Name = NULL
Reserve_Owner = user1@south.mydomain.com
reserve_state = RESV_RUNNING
reserve_substate = 5
reserve_start = Mon Apr 28 12:00:00 2008
reserve_end = Mon Apr 28 14:00:00 2008
reserve_duration = 7200
queue = R302
Resource_List.ncpus = 2
Resource_List.nodect = 1
Resource_List.walltime = 02:00:00
Resource_List.select = 1:ncpus=2
Resource_List.place = free
resv_nodes = (south:ncpus=2)
Authorized_Users = user1@south.mydomain.com
server = south
ctime = Mon Apr 28 11:00:00 2008
Mail_Users = user1@mydomain.com
mtime = Mon Apr 28 11:00:00 2008
Variable_List = PBS_O_LOGNAME=user1,PBS_O_HOST=south.mydomain.com

Name: S304.south
Reserve_Name = NULL
Reserve_Owner = user1@south.mydomain.com
reserve_state = RESV_CONFIRMED
reserve_substate = 2
reserve_start = Thu May 1 15:00:00 2008
reserve_end = Thu May 1 16:00:00 2008
reserve_duration = 3600
queue = S304
Resource_List.ncpus = 2
Resource_List.nodect = 1
Resource_List.walltime = 01:00:00
Resource_List.select = 1:ncpus=2
Resource_List.place = free
resv_nodes = (south:ncpus=2)
reserve_rrule = FREQ=WEEKLY;BYDAY=MO;COUNT=5
reserve_count = 5
reserve_index = 2
Authorized_Users = user1@south.mydomain.com
server = south
ctime = Mon Apr 28 11:01:00 2008
Mail_Users = user1@mydomain.com
```

```
mtime = Mon Apr 28 11:01:00 2008
Variable_List = PBS_O_LOGNAME=user1,PBS_O_HOST=south.mydomain.com,PBS_TZID=America/Los_Angeles
```

7.10 Submitting a Job to a Reservation

Jobs can be submitted to the queue associated with a reservation, or they can be moved from another queue into the reservation queue. You submit a job to a reservation by using the -q <*queue*> option to the qsub command to specify the reservation queue. For example, to submit a job to the soonest occurrence of a standing reservation named S123.south, submit to its queue S123:

```
qsub -q S123 <script>
```

You move a job into a reservation queue by using the qmove command. For more information, see "qsub" on page 216 of the PBS Professional Reference Guide and "qmove" on page 175 of the PBS Professional Reference Guide. For example, to qmove job 22.myhost from workq to S123, the queue for the reservation named S123.south:

```
qmove S123 22.myhost
```

or

```
qmove S123 22
```

A job submitted to a standing reservation without a restriction on when it can run will be run, if possible, during the soonest occurrence. In order to submit a job to a specific occurrence, use the -a <*start time*> option to the qsub command, setting the start time to the time of the occurrence that you want. You can also use a cron job to submit a job at a specific time. See "qsub" on page 216 of the PBS Professional Reference Guide and the cron(8) man page.

7.10.1 Who Can Use Your Reservation

By default, the reservation accepts jobs only from the user who created the reservation, and accepts jobs submitted from any group or host. You can specify a list of users and groups whose jobs will and will not be accepted by the reservation by setting the reservation's Authorized_Users and Authorized_Groups attributes using the -U <*authorized user list*> and -G <*authorized group list*> options to pbs_rsub and pbs_ralter. You can specify the hosts from which jobs can and cannot be submitted by setting the reservation's Authorized_Hosts attribute using the -H <*authorized host list*> option to pbs_rsub.

The administrator can also specify which users and groups can and cannot submit jobs to a reservation, and the list of hosts from which jobs can and cannot be submitted.

For more information, see "pbs_rsub" on page 96 of the PBS Professional Reference Guide and "Reservation Attributes" on page 303 of the PBS Professional Reference Guide.

7.10.2 Viewing Status of a Job Submitted to a Reservation

You can view the status of a job that has been submitted to a reservation or to an occurrence of a standing reservation by using the qstat command. See "qstat" on page 200 of the PBS Professional Reference Guide.

For example, if a job named MyJob has been submitted to the soonest occurrence of the standing reservation named S304.south, it is listed under S304, the name of the queue:

```
qstat

Job id      Name       User          Time Use  S  Queue
----------  ---------  ------------  --------  --  -----
139.south   MyJob      user1                0  Q  S304
```

7.10.3 How Reservations Treat Jobs

A confirmed reservation will accept jobs into its queue at any time. Jobs are only scheduled to run from the reservation once the reservation period arrives.

The jobs in a reservation are not allowed to use, in aggregate, more resources than the reservation requested. A reservation job is accepted in the reservation regardless of whether its requested walltime will fit within the reservation period. So for example if the reservation runs from 10:00 to 11:00, and the job's walltime is 4 hours, the job will be started.

When an advance reservation ends, any running or queued jobs in that reservation are deleted.

When an occurrence of a standing reservation ends, any running jobs in that reservation are killed. Any jobs still queued for that reservation are kept in the queued state. They are allowed to run in future occurrences. When the last occurrence of a standing reservation ends, all jobs remaining in the reservation are deleted, whether queued or running.

A job in a reservation cannot be preempted.

A job in a reservation runs with the normal job environment variables; see section 6.12, “Using Environment Variables”, on page 128.

7.10.3.1 Caveats for How Reservations Treat Jobs

If you submit a job to a reservation, and the job's walltime fits within the reservation period, but the time between when you submit the job and when the reservation ends is less than the job's walltime, PBS will start the job, and then kill it if it is still running when the reservation ends.

7.11 Reservation Caveats and Errors

7.11.1 Time Zone Must be Correct

The environment variable `PBS_TZID` must be set at the submission host. The time for which a reservation is requested is the time defined at the submission host. See section 1.4.4, “Setting Time Zone for Submission Host”, on page 9.

7.11.2 Time Required Between Reservations

Leave enough time between reservations for the reservations and jobs in them to clean up. A job consumes resources even while it is in the `E` or exiting state. This can take longer when large files are being staged. If the job is still running when the reservation ends, it may take up to two minutes to be cleaned up. The reservation itself cannot finish cleaning up until its jobs are cleaned up. This will delay the start time of jobs in the next reservation unless there is enough time between the reservations for cleanup.

7.11.3 Reservation Information in the Accounting Log

The PBS server writes an accounting record for each reservation in the job accounting file. The accounting record for a reservation is similar to that for a job. The accounting record for any job belonging to a reservation will include the reservation ID. See "Accounting" on page 529 in the PBS Professional Administrator’s Guide.

7.11.4 Reservation Fault Tolerance

If one or more vnodes allocated to a job-specific reservation, an advance reservation, or to the soonest occurrence of a standing reservation become unavailable, the reservation's state becomes *DG* or *RESV_DEGRADED*. A degraded reservation does not have all the reserved resources to run its jobs.

PBS attempts to reconfirm degraded reservations. This means that it looks for alternate available vnodes on which to run the reservation. The reservation's retry_time attribute lists the next time when PBS will try to reconfirm the reservation.

If PBS is able to reconfirm a degraded reservation, the reservation's state becomes *CO*, or *RESV_CONFIRMED*, and the reservation's resv_nodes attribute shows the new vnodes.

7.11.5 Job and Reservation Exclusivity Must Match

If your job requests exclusive placement, and it is in a reservation, the reservation must also request exclusive placement via `-l place=excl`.

8
Job Arrays

8.1 Advantages of Job Arrays

PBS provides job arrays, which are useful for collections of almost-identical jobs. Each job in a job array is called a "subjob". Subjobs are scheduled and treated just like normal jobs, with the exceptions noted in this chapter. You can group closely related work into a set so that you can submit, query, modify, and display the set as a unit. Job arrays are useful where you want to run the same program over and over on different input files. PBS can process a job array more efficiently than it can the same number of individual normal jobs. Job arrays are suited for SIMD operations, for example, parameter sweep applications, rendering in media and entertainment, EDA simulations, and forex (historical data).

8.2 Glossary

Job array identifier

The identifier returned upon success when submitting a job array. Format:

<sequence number>[]

Job array range

A set of subjobs within a job array. When specifying a range, indices used must be valid members of the job array's indices.

Sequence number

The numeric part of a job or job array identifier, e.g. *1234*.

Subjob

Individual entity within a job array (e.g. *1234[7]*, where *1234[]* is the job array itself, and *7* is the index) which has many properties of a job as well as additional semantics (defined below.)

Subjob index

The unique index which differentiates one subjob from another. This must be a non-negative integer.

8.3 Description of Job Arrays

A job array is a compact representation of two or more jobs. A job that is part of a job array is called a "subjob". Each subjob in a job array is treated exactly like a normal job, except for any differences noted in this chapter.

8.3.1 Job Script for Job Arrays

All subjobs in a job array share a single job script, including the PBS directives and the shell script portion. The job script is run once for each subjob.

The job script may invoke different commands based on the subjob index. The commands of course may be scripts themselves. You can do this by naming different commands with the subjob index or via "if" statements in the script.

8.3.2 Attributes and Resources for Job Arrays

All subjobs in one job array have the same attributes, including resource requirements and limits.

The same job script runs for each subjob in the job array. If the job script calls other scripts or commands, those scripts or commands cannot change the attributes and resources for individual subjobs, because PBS stops processing directives when it starts processing commands.

8.3.3 Scheduling Job Arrays and Subjobs

The scheduler handles each subjob in a job array as a separate job. All subjobs within a job array have the same scheduling priority.

8.3.4 Identifier Syntax

The sequence number (1234 in 1234[].<server>) is unique, so that jobs and job arrays cannot share a sequence number. The job identifiers of the subjobs in the same job array are the same except for their indices. Each subjob has a unique index. You can refer to job arrays or parts of job arrays using the following syntax forms:

- The job array object itself: The format is *<sequence number>[]* or *<sequence number>[].<server>.<domain>.com*

  Example: 1234[].myserver or 1234[]
- A single subjob with index *M*: The format is *<sequence number>[M]* or *<sequence number>[M].<server>.<domain>.com*

  Example where *M*=17: 1234[17].myserver or 1234[17]
- A range of subjobs of a job array: The format is *<sequence number>[start-end[:step]]* or *<sequence number>[start-end[:step]].<server>.<domain>.com*

  Example where we start at 2, end at 8, and the step is 3: 1234[2-8:3].myserver or 1234[2-8:3]

8.3.4.1 Examples of Using Identifier Syntax

1234[]	Short job array identifier
1234[].myserver.domain.com	Full job array identifier
1234[73]	Short subjob identifier of the 73rd index of job array 1234[]
1234[73].myserver.domain.com	Full subjob identifier of the 73rd index of job array 1234[]

8.3.4.2 Shells and Array Identifiers

Since some shells, for example `csh` and `tcsh`, read "[" and "]" as shell metacharacters, job array names and subjob names must be enclosed in double quotes for all PBS commands.

Example:

```
qdel "1234[5].myhost"
qdel "1234[].myhost"
```

Single quotes will work, except where you are using shell variable substitution.

8.3.5 Special Attributes for Job Arrays

Job arrays and subjobs have all of the attributes of a job. In addition, they have the following when appropriate. These attributes are read-only.

Table 8-1: Job Array Attributes

Name	Type	Applies To	Value
array	Boolean	Job array	*True* if item is job array
array_id	String	Subjob	Subjob's job array identifier
array_index	String	Subjob	Subjob's index number
array_indices_remaining	String	Job array	List of indices of subjobs still queued. Range or list of ranges, e.g. *500*, *552*, *596-1000*
array_indices_submitted	String	Job array	Complete list of indices of subjobs given at submission time. Given as range, e.g. *1-100*
array_state_count	String	Job array	Similar to state_count attribute for server and queue objects. Lists number of subjobs in each state.
max_run_subjobs	Integer	Job array	Limit on number of subjobs that can be running at one time.

8.3.6 Job Array States

The state of subjobs in the same job array can be different. See "Job Array States" on page 363 of the PBS Professional Reference Guide and "Subjob States" on page 363 of the PBS Professional Reference Guide.

8.3.7 PBS Environmental Variables for Job Arrays

Table 8-2: PBS Environmental Variables for Job Arrays

Environment Variable Name	Used For	Description
PBS_ARRAY_INDEX	Subjobs	Subjob index in job array, e.g. 7
PBS_ARRAY_ID	Subjobs	Identifier for a job array. Sequence number of job array, e.g. 1234[].myserver
PBS_JOBID	Jobs, subjobs	Identifier for a job or a subjob. For subjob, sequence number and subjob index in brackets, e.g. 1234[7].myserver

8.3.8 Accounting

Job accounting records for job arrays and subjobs are the same as for jobs. When a job array has been moved from one server to another, the subjob accounting records are split between the two servers.

Subjobs do not have "Q" records.

8.3.9 Prologues and Epilogues

If defined, prologues and epilogues run at the beginning and end of each subjob, but not for the array object.

8.3.10 The "Rerunnable" Flag and Job Arrays

Job arrays are required to be rerunnable. PBS will not accept a job array that is marked as not rerunnable. You can submit a job array without specifying whether it is rerunnable, and PBS will automatically mark it as rerunnable.

8.4 Submitting a Job Array

8.4.1 Job Array Submission Syntax

You submit a job array through a single command. You specify subjob indices, and optionally a limit on the number of subjobs that can be running at one time, at submission.

For the range, you can specify any of the following:

- A contiguous range, e.g. 1 through 100
- A range with a stepping factor, e.g. every second entry in 1 through 100 (1, 3, 5, ... 99)

The limit is an optional percent sign followed by an integer.

Syntax for submitting a job array:

qsub -J <index start>-<index end>[:<stepping factor>] [%<max subjobs>]

where

index start is the lowest index number in the range

index end is the highest index number in the range

stepping factor is the optional difference between index numbers

max subjobs is the limit on the number of subjobs that can be running at one time

The index start and end must be whole numbers, and the stepping factor must be a positive integer. The index end must be greater than the index start. If the index end is not a multiple of the stepping factor above the index start, it will not be used as an index value, and the highest index value used will be lower than the index end. For example, if index start is 1, index end is 8, and the stepping factor is 3, the index values are 1, 4, and 7.

8.4.1.1 Limiting Number of Simultaneously Running Subjobs

By default PBS simultaneously runs as many subjobs from a job array as possible. You can limit the number of subjobs that are running at one time by setting the value of the max_run_subjobs job attribute. This is helpful if for example every subjob needs access to the same shared data file and you want to prevent slowdowns due to an access bottleneck. You can set the limit at submission by appending %<max subjobs> to your `-J` option:

qsub -J <index start>-<index end>[:<stepping factor>] [%<max subjobs>]

For example:

```
qsub -J 1-20000 %500 myscript.sh
```

Or you can use `qalter` to set or change the max_run_subjobs attribute:

qalter -Wmax_run_subjobs=<new value> <job ID>

For example:

```
qalter -Wmax_run_subjobs=1000 123[].myserver
```

Suspended subjobs do not count against the limit set in max_run_subjobs.

8.4.2 Examples of Submitting Job Arrays

Example 8-1: To submit a job array of 10,000 subjobs, with indices 1, 2, 3, ... 10000:

```
$ qsub -J 1-10000 job.scr
1234[].server.domain.com
```

Example 8-2: To submit a job array of 500 subjobs, with indices 500, 501, 502, ... 1000:

```
$ qsub -J 500-1000 job.scr
1235[].server.domain.com
```

Example 8-3: To submit a job array with indices 1, 3, 5 ... 999:

```
$ qsub -J 1-1000:2 job.scr
1236[].server.domain.com
```

Example 8-4: To submit a job array of 10,000 subjobs with indices 1, 2, 3, ... 10000, and a limit of 500 simultaneously running subjobs:

```
$ qsub -J 1-10000 %500 job.scr
1237[].server.domain.com
```

8.4.3 File Staging for Job Arrays

When preparing files to be staged for a job array, plan on naming the files so that they match the index numbers of the subjobs. For example, `inputfile3` is meant to be used by the subjob with index value *3*.

To stage files for job arrays, you use the same mechanism as for normal jobs, but include a variable to specify the subjob index. This variable is named *array_index*.

8.4.3.1 File Staging Syntax for Job Arrays

You can specify files to be staged in before the job runs and staged out after the job runs. Format:

qsub -W stagein=<stagein file list> -W stageout=<stageout file list>

You can use these as options to `qsub`, or as directives in the job script.

For both stagein and stageout, the *file list* has the form:

<execution path>^array_index^@<storage host>:<storage path>^array_index^[,...]

The name *<execution path><index number>* is the name of the file in the job's staging and execution directory (on the execution host). The *execution path* can be relative to the job's staging and execution directory, or it can be an absolute path.

The '@' character separates the execution specification from the storage specification.

The name *<storage path><index number>* is the file name on the host specified by *storage host*. For stagein, this is the location where the input files come from. For stageout, this is where the output files end up when the job is done. You must specify a *storage host*. The name can be absolute, or it can be relative to your home directory on the storage machine.

For stagein, the direction of travel is **from** *storage path* **to** *execution path*.

For stageout, the direction of travel is **from** *execution path* **to** *storage path*.

When staging more than one set of filenames, separate the filenames with a comma and enclose the entire list in double quotes.

8.4.3.2 Job Array Staging Syntax on Windows

In Windows the stagein and stageout string must be contained in double quotes when using ^array_index^.

Example of a stagein:

```
qsub -W stagein="foo.^array_index^@host-1:C:\WINNT\Temp\foo.^array_index^" -J 1-5 stage_script
```

Example of a stageout:

```
qsub -W stageut="C:\WINNT\Temp\foo.^array_index^@host-1:Q:\my_username\foo. ^array_index^_out" -J
    1-5 stage_script
```

8.4.3.3 Job Array File Staging Caveats

We recommend using an absolute pathname for the *storage path*. Remember that the path to your home directory may be different on each machine, and that when using sandbox = *PRIVATE*, you may or may not need to have a home directory on all execution machines.

8.4.3.4 Examples of Staging for Job Arrays

Example 8-5: Simple example:

Storage path: `store:/film`

Data files used as input: `frame1`, `frame2`, `frame3`

execution path: `pix`

Executable: `a.out`

For this example, `a.out` produces `frame2.out` from `frame2`.

```
#PBS -W stagein=pix/in/frame^array_index^@store:/film/frame^array_index^
#PBS- W stageout=pix/out/frame^array_index^.out @store:/film/frame^array_index^.out
#PBS -J 1-3 a.out frame$PBS_ARRAY_INDEX ./in ./out
```

Note that the stageout statement is all one line.

The result is that your directory named "`film`" contains the original files `frame1`, `frame2`, `frame3`, plus the new files `frame1.out`, `frame2.out`, and `frame3.out`.

Example 8-6: In this example, we have a script named ArrayScript which calls `scriptlet1` and `scriptlet2`.

All three scripts are located in `/homedir/testdir`.

```
#!/bin/sh
#PBS -N ArrayExample
#PBS -J 1-2
echo "Main script: index " $PBS_ARRAY_INDEX
/homedir/testdir/scriptlet$PBS_ARRAY_INDEX
```

In our example, scriptlet1 and scriptlet2 simply echo their names. We run ArrayScript using the qsub command:

```
qsub ArrayScript
```

Example 8-7: In this example, we have a script called StageScript. It takes two input files, dataX and extraX, and makes an output file, newdataX, as well as echoing which iteration it is on. The dataX and extraX files will be staged from inputs to work, then newdataX will be staged from work to outputs.

```
#!/bin/sh
#PBS -N StagingExample
#PBS -J 1-2
#PBS -W stagein="/homedir/work/data^array_index^@host1:/homedir/inputs/data^array_index^, \
    /homedir/work/extra^array_index^ @host1:/homedir/inputs/extra^array_index^"
#PBS -W stageout=/homedir/work/newdata^array_index^@host1:/homedir/outputs/newdata^array_index^
echo "Main script: index " $PBS_ARRAY_INDEX
cd /homedir/work
cat data$PBS_ARRAY_INDEX extra$PBS_ARRAY_INDEX >> newdata$PBS_ARRAY_INDEX
```

Execution path:

```
/homedir/work
```

Storage host:

```
host1
```

Storage path for inputs (original data files dataX and extraX):

```
/homedir/inputs
```

Storage path for results (output of computation newdataX):

```
/homedir/outputs
```

StageScript resides in /homedir/testdir. In that directory, we can run it by typing:

```
qsub StageScript
```

It will run in /homedir, our home directory, which is why the line

```
"cd /homedir/work"
```

is in the script.

Example 8-8: In this example, we have the same script as before, but we will run it in a staging and execution directory created by PBS. StageScript takes two input files, dataX and extraX, and makes an output file, newdataX, as well as echoing which iteration it is on. The dataX and extraX files will be staged from inputs to the staging and execution directory, then newdataX will be staged from the staging and execution directory to outputs.

```
#!/bin/sh
#PBS -N StagingExample
#PBS -J 1-2
#PBS -W stagein="data^array_index^@host1:/homedir/inputs/data^array_index^, \
    extra^array_index^@host1:/homedir/inputs/extra^array_index^"
#PBS -W stageout=newdata^array_index^@host1:/homedir/outputs/newdata^array_index^
echo "Main script: index " $PBS_ARRAY_INDEX
cat data$PBS_ARRAY_INDEX extra$PBS_ARRAY_INDEX >> newdata$PBS_ARRAY_INDEX
```

Execution path (directory): created by PBS; we don't know the name

Storage host:

```
host1
```

Storage path for inputs (original data files dataX and extraX):

`/homedir/inputs`

Storage path for results (output of computation newdataX):

`/homedir/outputs`

StageScript resides in /homedir/testdir. In that directory, we can run it by typing:

`qsub StageScript`

It will run in the staging and execution directory created by PBS. See section 3.2, “Input/Output File Staging”, on page 33.

8.4.4 Filenames for Standard Output and Standard Error

The name for `stdout` for a subjob defaults to *<job name>.o<sequence number>.<index>*, and the name for `stderr` for a subjob defaults to *<job name>.e<sequence number>.<index>*.

Example 8-9: The job is named "fixgamma" and the sequence number is "1234".

The subjob with index 7 is 1234[7].<server name>. For this subjob, `stdout` and `stderr` are named `fixgamma.o1234.7` and `fixgamma.e1234.7`.

8.4.5 Job Array Dependencies

Job dependencies are supported for the following relationships:

- Between job arrays and job arrays
- Between job arrays and jobs
- Between jobs and job arrays

8.4.5.1 Caveats for Job Array Dependencies

Job dependencies are not supported for subjobs or ranges of subjobs.

8.4.6 Job Array Exit Status

The exit status of a job array is determined by the status of each of the completed subjobs. It is only available when all valid subjobs have completed. The individual exit status of a completed subjob is passed to the epilogue, and is available in the 'E' accounting log record of that subjob.

Table 8-3: Job Array Exit Status

Exit Status	Meaning
0	All subjobs of the job array returned an exit status of 0. No PBS error occurred. Deleted subjobs are not considered
1	At least 1 subjob returned a non-zero exit status. No PBS error occurred.
2	A PBS error occurred.

8.4.6.1 Making `qsub` Wait Until Job Array Finishes

Blocking `qsub` waits until the entire job array is complete, then returns the exit status of the job array.

8.4.6.2 Caveats for Job Array Exit Status

Subjob exit status is available only as long as the subjob is in job history. When a subjob is not in job history, a failed or terminated subjob will show an exit status of *Finished*, instead of failed or terminated.

8.4.7 Caveats for Submitting Job Arrays

8.4.7.1 No Interactive Job Submission of Job Arrays

Interactive submission of job arrays is not allowed.

8.5 Viewing Status of a Job Array

You can use the `qstat` command to query the status of a job array. The default output is to list the job array in a single line, showing the job array identifier. You can combine options.

You can use the `-f` option to the `qstat` command to see all of a subjob's attributes.

To show the state of all running subjobs, use `-t -r`. To show the state of subjobs only, not job arrays, use `-t -J`.

Table 8-4: Job Array and Subjob Options to `qstat`

Option	Result
-t	Shows state of job array object and subjobs. Also shows state of jobs.
-J	Shows state only of job arrays.
-p	Prints the default display, with column for Percentage Completed. For a job array, this is the number of subjobs completed or deleted divided by the total number of subjobs. For a job, it is time used divided by time requested.

8.5.1 Example of Viewing Job Array Status

We run an example job and an example job array, on a machine with 2 processors:

`demoscript`:

```
#!/bin/sh
#PBS -N JobExample
sleep 60
```

`arrayscript`:

```
#!/bin/sh
#PBS -N ArrayExample
#PBS -J 1-5
sleep 60
```

We run these scripts using `qsub`:

```
qsub arrayscript
1235[].host
qsub demoscript
1236.host
```

We query using various options to `qstat`:

```
qstat
Job id      Name         User        Time Use S Queue
----------- ------------ ----------  -------- - -----
1235[].host ArrayExample user1              0 B workq
1236.host   JobExample   user1              0 Q workq

qstat -J
Job id      Name         User        Time Use S Queue
----------- ------------ ----------  -------- - -----
1235[].host ArrayExample user1              0 B workq

qstat -p
Job id      Name         User        % done  S Queue
----------- ------------ ----------  ------- - -----
1235[].host ArrayExample user1            0  B workq
1236.host   JobExample   user1           --  Q workq

qstat -t
Job id       Name         User        Time Use S Queue
-----------  ------------ ----------  -------- - -----
1235[].host  ArrayExample user1              0 B workq
1235[1].host ArrayExample user1       00:00:00 R workq
1235[2].host ArrayExample user1       00:00:00 R workq
1235[3].host ArrayExample user1              0 Q workq
1235[4].host ArrayExample user1              0 Q workq
1235[5].host ArrayExample user1              0 Q workq
1236.host    JobExample   user1              0 Q workq

qstat -Jt
Job id       Name         User   Time Use S Queue
------------ ------------ -----  -------- - -----
1235[1].host ArrayExample user1  00:00:00 R workq
1235[2].host ArrayExample user1  00:00:00 R workq
1235[3].host ArrayExample user1         0 Q workq
1235[4].host ArrayExample user1         0 Q workq
1235[5].host ArrayExample user1         0 Q workq
```

After the first two subjobs finish:

```
qstat -Jtp
Job id       Name         User   % done S Queue
------------ ------------ -----  ------ - -----
1235[1].host ArrayExample user1     100 X workq
1235[2].host ArrayExample user1     100 X workq
1235[3].host ArrayExample user1      -- R workq
1235[4].host ArrayExample user1      -- R workq
1235[5].host ArrayExample user1      -- Q workq

qstat -pt
Job id       Name         User   % done S Queue
------------ ------------ -----  ------ - -----
1235[].host  ArrayExample user1      40 B workq
1235[1].host ArrayExample user1     100 X workq
1235[2].host ArrayExample user1     100 X workq
1235[3].host ArrayExample user1      -- R workq
1235[4].host ArrayExample user1      -- R workq
1235[5].host ArrayExample user1      -- Q workq
1236.host    JobExample   user1      -- Q workq
```

Now if we wait until only the last subjob is still running:

```
qstat -rt
                                                    Req'd  Req'd  Elap
Job ID     Username Queue Jobname   SessID NDS TSK Memory Time S Time
---------- ------  ----- ---------  ---- --- --- ------ ---- - -----
1235[5].host user1  workq ArrayExamp 3048  --   1    --    --  R 00:00
1236.host    user1  workq JobExample 3042  --   1    --    --  R 00:00

qstat -Jrt
                                                    Req'd  Req'd  Elap
Job ID      Username Queue Jobname  SessID NDS TSK Memory Time S Time
----------- -------- ----- --------- ---- --- --- ------ ---- - -----
1235[5].host   user1 workq ArrayExamp 048 --   1    --    --  R 00:01
```

8.6 Using PBS Commands with Job Arrays

The following table shows how you can or cannot use PBS commands with job arrays, subjobs or ranges:

Table 8-5: Using PBS Commands with Job Arrays

	Argument to Command		
Command	**Array[]: Array Object**	**Array[Range]: Specified Range of Subjobs**	**Array[Index]: Specified Subjob**
`qalter`	Array object	erroneous	erroneous
`qdel`	Array object & Running subjobs	Running subjobs in specified range	Specified subjob
`qhold`	Array object & Queued subjobs	erroneous	erroneous
`qmove`	Array object & Queued subjobs	erroneous	erroneous
`qmsg`	erroneous	erroneous	erroneous
`qorder`	Array object	erroneous	erroneous
`qrerun`	Running and finished subjobs	Running subjobs in specified range	Specified subjob
`qrls`	Array object & Queued subjobs	erroneous	erroneous
`qsig`	Running subjobs	Running subjobs in specified range	Specified subjob
`qstat`	Array object	Specified range of subjobs	Specified subjob
`tracejob`	erroneous	erroneous	Specified subjob

8.6.1 Deleting a Job Array

The `qdel` command will take a job array identifier, subjob identifier or job array range. The indicated object(s) are deleted, including any currently running subjobs. Running subjobs are treated like running jobs. Subjobs not running are deleted and never run.

By default, one email is sent per deleted subjob, so deleting a job array of 5000 subjobs results in 5000 emails being sent, unless you are suppressing the number of emails sent. See "-Wsuppress_email=<N>" on page 144 of the PBS Professional Reference Guide.

8.6.2 Altering a Job Array

The `qalter` command can only be used on a job array object, not on subjobs or ranges. Job array attributes are the same as for jobs.

To modify the max_run_subjobs attribute, use `qalter -Wmax_run_subjobs=<new value> <job ID>`.

8.6.3 Moving a Job Array

The `qmove` command can only be used with job array objects, not with subjobs or ranges. Job arrays can only be moved from one server to another if they are in the '*Q*', '*H*', or '*W*' states, and only if there are no running subjobs. The state of the job array object is preserved in the move. The job array will run to completion on the new server.

As with jobs, a `qstat` on the server from which the job array was moved does not show the job array. A `qstat` on the job array object is redirected to the new server.

8.6.4 Holding a Job Array

The `qhold` command can only be used with job array objects, not with subjobs or ranges. A hold can be applied to a job array only from the '*Q*', '*B*' or '*W*' states. This puts the job array in the '*H*', held, state. If any subjobs are running, they will run to completion. No queued subjobs are started while in the '*H*' state.

If a job array has subjobs that have a System hold, the job array also gets a System hold.

8.6.5 Releasing a Job Array

The `qrls` command can be used directly only with job array objects, not with subjobs or ranges. If the job array was in the '*Q*' or '*B*' state, it is returned to that state. If it was in the '*W*' state, it is returned to that state, unless its waiting time was reached, in which case it goes to the '*Q*' state.

You can use `qrls` indirectly on subjobs. If you use `qrls` on a job array, and that job array has a System hold because it has subjobs(s) with a System hold, the subjobs that were held with a System hold are released, then the System hold on the job array is released (you'll need Manager, root, or PBS Administrator privilege for this).

8.6.6 Selecting Job Arrays

The default behavior of `qselect` is to return the job array identifier, without returning subjob identifiers.

The `qselect` command does not return any job arrays when the state selection (`-s`) option restricts the set to '*R*', '*S*', '*T*' or '*U*', because a job array will never be in any of these states. However, you can use `qselect` to return a list of subjobs by using the `-t` option.

You can combine options to `qselect`. For example, to restrict the selection to subjobs, use both the `-J` and the `-T` options. To select only running subjobs, use `-J -T -sR`.

Table 8-6: Options to qselect for Job Arrays

Option	Selects	Result
(none)	jobs, job arrays	Shows job and job array identifiers
-J	job arrays	Shows only job array identifiers
-T	jobs, subjobs	Shows job and subjob identifiers

8.6.7 Ordering Job Arrays in the Queue

The `qorder` command can only be used with job array objects, not on subjobs or ranges. This changes the queue order of the job array in association with other jobs or job arrays in the queue.

8.6.8 Requeueing a Job Array

The `qrerun` command will take a job array identifier, subjob identifier or job array range. If a job array identifier is given as an argument, it is returned to its initial state at submission time, or to its altered state if it has been qaltered. All of that job array's subjobs are requeued, which includes those that are currently running, and those that are completed and deleted. If a subjob or range is given, those subjobs are requeued as jobs would be.

8.6.9 Signaling a Job Array

If a job array object, subjob or job array range is given to `qsig`, all currently running subjobs within the specified set are sent the signal.

8.6.10 Sending Messages to Job Arrays

The `qmsg` command is not supported for job arrays.

8.6.11 Getting Log Data on Job Arrays

The `tracejob` command can be run on job arrays and individual subjobs. When `tracejob` is run on a job array or a subjob, the same information is displayed as for a job, with additional information for a job array. Note that subjobs do not exist until they are running, so `tracejob` will not show any information until they are. When `tracejob` is run on a job array, the information displayed is only that for the job array object, not the subjobs. Job arrays themselves do not produce any MoM log information. Running `tracejob` on a job array gives information about why a subjob did not start.

8.6.12 Caveats for Using PBS Commands with Job Arrays

8.6.12.1 Shells and PBS Commands with Job Arrays

Some shells such as `csh` and `tcsh` use the square bracket ("[", "]") as a metacharacter. When using one of these shells, and a PBS command taking subjobs, job arrays or job array ranges as arguments, the subjob, job array or job array range must be enclosed in double quotes.

8.7 Job Array Caveats

8.7.1 Job Arrays Required to be Rerunnable

Job arrays are required to be rerunnable, and are rerunnable by default.

8.7.2 Resources Same for All Subjobs

You cannot combine jobs into an array that have different hardware requirements, i.e. different select statements.

8.7.3 Checkpointing Not Supported for Job Arrays

Checkpointing is not supported for job arrays. On systems that support checkpointing, subjobs are not checkpointed, instead they run to completion.

8.7.4 Caveats for Job Array Exit Status

Subjob exit status is available only as long as the subjob is in job history. When a subjob is not in job history, a failed or terminated subjob will show an exit status of *Finished*, instead of failed or terminated.

9 Working with PBS Jobs

9.1 Using Job History

PBS Professional can provide job history information, including what the submission parameters were, whether the job started execution, whether execution succeeded, whether staging out of results succeeded, and which resources were used.

PBS can keep job history for jobs which have finished execution, were deleted, or were moved to another server.

9.1.1 Definitions

Moved jobs

Jobs which were moved to another server

Finished jobs

Jobs whose execution is done, for any reason:

- Jobs which finished execution successfully and exited
- Jobs terminated by PBS while running
- Jobs whose execution failed because of system or network failure
- Jobs which were deleted before they could start execution

9.1.2 Job History Information

PBS can keep all job attribute information, including the following:

- Submission parameters
- Whether the job started execution
- Whether execution succeeded
- Whether staging out of results succeeded
- Which resources were used

PBS keeps job history for the following jobs:

- Jobs that are running at another server
- Jobs that have finished execution
- Jobs that were deleted
- Jobs that were moved to another server

While a job is running, you can see information about it. After a job has finished or been deleted, its history information is preserved for the specified duration. The administrator chooses a duration for preservation of job history information after each job has finished or been deleted. PBS periodically checks each finished job, and deletes job history for those whose history has been preserved for longer than the specified duration.

Subjobs are not considered finished jobs until the parent array job is finished, which happens when all of its subjobs have terminated execution.

9.1.2.1 Working With Moved Jobs

You can use the following commands with moved jobs. They will function as they do with normal jobs.

```
qalter
qhold
qmove
qmsg
qorder
qrerun
qrls
qrun
qsig
```

While a moved job is running, its state is *M*. When a moved job finishes, its substate becomes *92*. See "Job States" on page 361 of the PBS Professional Reference Guide.

9.1.2.2 PBS Commands and Finished Jobs

The commands listed above cannot be used with finished jobs, whether they finished at the local server or a remote server. These jobs are no longer running; PBS is storing their information, and this information cannot be altered. Trying to use one of the above commands with a finished job results in the following error message:

```
<command name>: Job <job ID> has finished
```

9.2 Modifying Job Attributes

Most attributes can be changed by the owner of the job (or a manager or operator) while the job is still queued. However, once a job begins execution, the only values that can be modified are cputime, walltime, and run_count. You can decrease walltime, and you can increase run_count.

When the `qalter -l` option is used to alter the resource list of a queued job, it is important to understand the interactions between altering the select directive and job limits.

If the job was submitted with an explicit "`-l select=`", then vnode-level resources must be qaltered using the "`-l select=`" form. In this case a vnode level resource RES cannot be qaltered with the "`-l <resource>`" form.

For example:

Submit the job:

```
% qsub -l select=1:ncpus=2:mem=512mb jobscript
```

Job's ID is 230

`qalter` the job using "-l RES" form:

```
% qalter -l ncpus=4 230
```

Error reported by `qalter`:

```
qalter: Resource must only appear in "select"
```

specification when select is used: ncpus 230

qalter the job using the "-l select=" form:

```
% qalter -l select=1:ncpus=4:mem=512mb 230
```

No error reported by qalter:

```
%
```

9.2.1 Changing the Selection Directive

If the selection directive is altered, the job limits for any consumable resource in the directive are also modified.

For example, if a job is queued with the following resource list:

```
select=2:ncpus=1:mem=5gb
```

job limits are set to ncpus=2, mem=10gb.

If the select statement is altered to request:

```
select=3:ncpus=2:mem=6gb
```

then the job limits are reset to ncpus=6 and mem=18gb

9.2.2 Changing the Job-wide Limit

If the job-wide limit is modified, the corresponding resources in the selection directive are not modified. It would be impossible to determine where to apply the changes in a compound directive.

Reducing a job-wide limit to a new value less than the sum of the resource in the directive is strongly discouraged. This may produce a situation where the job is aborted during execution for exceeding its limits. The actual effect of such a modification is not specified.

A job's walltime may be altered at any time, except when the job is in the *Exiting* state, regardless of the initial value.

If a job is queued, requested modifications must still fit within the queue's and server's job resource limits. If a requested modification to a resource would exceed the queue's or server's job resource limits, the resource request will be rejected.

Resources are modified by using the -l option, either in chunks inside of selection statements, or in job-wide modifications using resource_name=value pairs. The selection statement is of the form:

-l select=[N:]chunk[+[N:]chunk ...]

where N specifies how many of that chunk, and a chunk is of the form:

<resource name>=<value>[:<resource name>=<value> ...]

Job-wide *<resource name>=<value>* modifications are of the form:

-l <resource name>=<value>[,<resource name>=<value> ...]

Placement of jobs on vnodes is changed using the place statement:

-l place=<modifier>[:<modifier>]

where *modifier* is any combination of *group*, *excl*, *exclhost*, and/or one of *free*|*pack*|*scatter*|*vscatter*.

The usage syntax for qalter is:

qalter <job resources> <job list>

The following examples illustrate how to use the `qalter` command. First we list all the jobs of a particular user. Then we modify two attributes as shown (increasing the wall-clock time from 20 to 25 minutes, and changing the job name from "airfoil" to "engine"):

```
qstat -u barry
                                                  Req'd  Elap
Job ID   User   Queue Jobname Sess NDS TSK Mem Time S Time
-------- ------ ----- ------- ---- --- --- --- ---- - ----
51.south barry  workq airfoil  930  --   1  -- 0:16 R 0:01
54.south barry  workq airfoil  --   --   1  -- 0:20 Q  --

qalter -l walltime=20:00 -N engine 54
qstat -a 54
                                                  Req'd  Elap
Job ID   User   Queue Jobname Sess NDS TSK Mem Time S Time
-------- ------ ----- ------- ---- --- --- --- ---- - ----
54.south barry  workq engine   --   --   1  -- 0:25 Q  --
```

The `qalter` command can be used on job arrays, but not on subjobs or ranges of subjobs. When used with job arrays, any job array identifiers must be enclosed in double quotes, e.g.:

```
qalter -l walltime=25:00 "1234[].south"
```

You cannot use the `qalter` command (or any other command) to alter a custom resource which has been created to be invisible or unrequestable. See section 4.3.8, “Caveats and Restrictions on Requesting Resources”, on page 59.

For more information, see “qalter” on page 130 of the PBS Professional Reference Guide.

9.2.2.1 Caveats

Be careful when using a Boolean resource as a job-wide limit.

9.3 Deleting Jobs

PBS provides the `qdel` command for deleting jobs. The `qdel` command deletes jobs in the order in which their job identifiers are presented to the command. A batch job may be deleted by its owner, a PBS operator, or a PBS administrator. Unless you are an administrator or an operator, you can delete only your own jobs.

To delete a queued, held, running, or suspended job:

qdel <job ID>

Example:

```
qdel 51
qdel 1234[].server
```

Job array identifiers must be enclosed in double quotes.

9.3.1 Deleting Jobs with Force

You can delete a job whether or not its execution host is reachable, and whether or not it is in the process of provisioning:

qdel -W force <job ID>

9.3.2 Deleting Finished Jobs

By default, the qdel command does not affect finished jobs. You can use the qdel -x option to delete job histories. This option also deletes any specified jobs that are queued, running, held, suspended, finished, or moved. When you use this, you are deleting the job and its history in one step. If you use the qdel command without the -x option, you delete the job, but not the job history, and you cannot delete a finished job.

To delete a finished job, whether or not it was moved:

qdel -x <job ID>

If you try to delete a finished job without the -x option, you will get the following error:

```
qdel: Job <job ID> has finished
```

9.3.3 Deleting Moved Jobs

You can use the qdel -x option to delete jobs that are queued, running, held, suspended, finished, or moved.

To delete a job that was moved:

qdel <job ID sequence number>.<original server>

To delete a job that was moved, and then finished:

qdel -x <job ID>

9.3.4 Restricting Number of Emails

By default, mail is sent for each job or subjob you delete. Use the following option to qdel to specify a limit on emails sent:

qdel -Wsuppress_email=<N>

See section 2.5.1.3, “Restricting Number of Job Deletion Emails”, on page 27.

9.4 Sending Messages to Jobs

To send a message to a job is to write a message string into one or more output files of the job. Typically this is done to leave an informative message in the output of the job. Such messages can be written using the qmsg command.

You can send messages to running jobs only.

The usage syntax of the qmsg command is:

qmsg [-E][-O] <message string> <job ID>

Example:

```
qmsg -O "output file message" 54
qmsg -O "output file message" "1234[].server"
```

Job array identifiers must be enclosed in double quotes.

The -E option writes the message into the error file of the specified job(s). The -O option writes the message into the output file of the specified job(s). If neither option is specified, the message will be written to the error file of the job.

The first operand, *message_string*, is the message to be written. If the string contains blanks, the string must be quoted. If the final character of the string is not a newline, a newline character will be added when written to the job's file. All remaining operands are job IDs which specify the jobs to receive the message string. For example:

```
qmsg -E "hello to my error (.e) file" 55
qmsg -O "hello to my output (.o) file" 55
qmsg "this too will go to my error (.e) file" 55
```

9.5 Sending Signals to Jobs

You can use the `qsig` command to send a signal to your job. The signal is sent to all of the job's processes.

Usage syntax of the `qsig` command is:

qsig [-s <signal>] <job ID>

Job array *job IDs* must be enclosed in double quotes.

If the `-s` option is not specified, SIGTERM is sent. If the `-s` option is specified, it declares which *signal* is sent to the job. The *signal* argument is either a signal name, e.g. SIGKILL, the signal name without the *SIG* prefix, e.g. *KILL*, or an unsigned signal number, e.g. *9*. The signal name SIGNULL is allowed; the server will send the signal 0 to the job which will have no effect. Not all signal names will be recognized by `qsig`. If it doesn't recognize the signal name, try issuing the signal number instead. The request to signal a batch job will be rejected if:

- You are not authorized to signal the job
- The job is not in the running state
- The requested signal is not supported by the execution host
- The job is exiting
- The job is provisioning

Two special signal names, "suspend" and "resume", (note, all lower case), are used to suspend and resume jobs. When suspended, a job continues to occupy system resources but is not executing and is not charged for walltime. Manager or operator privilege is required to suspend or resume a job.

The signal TERM is useful, because it is ignored by shells, but you can trap it and do useful things such as write out status.

The three examples below all send a signal 9 (SIGKILL) to job 34:

```
qsig -s SIGKILL 34
qsig -s KILL 34
```

If you want to trap the signal in your job script, the signal must be trapped by all of the job's shells.

On most Linux systems the command "`kill -l`" (that's 'minus ell') will list all the available signals.

9.6 Changing Order of Jobs

PBS provides the `qorder` command to change the order of two jobs, within or across queues. To order two jobs is to exchange the jobs' positions in the queue or queues in which the jobs reside. If job1 is at position 3 in queue A and job2 is at position 4 in queue B, qordering them will result in job1 being in position 4 in queue B and job2 being in position 3 in queue A.

No attribute of the job (such as Priority) is changed. The impact of changing the order within the queue(s) is dependent on local job scheduling policy; contact your systems administrator for details.

Usage of the `qorder` command is:

qorder <job ID>1 <job ID2>

Job array identifiers must be enclosed in double quotes.

Both operands are *job IDs* which specify the jobs to be exchanged.

```
qstat -u bob
                                                  Req'd  Elap
Job ID   User   Queue Jobname Sess NDS TSK Mem Time S Time
-------- ------ ----- ------- ---- --- --- --- ---- - ----
54.south bob    workq twinkie  --   --   1  -- 0:20 Q  --
63[].south bob  workq airfoil  --   --   1  -- 0:13 Q  --

qorder 54 "63[]"
qstat -u bob
                                               Req'd     Elap
Job ID   User   Queue Jobname Sess NDS TSK Mem Time S Time
-------- ------ ----- ------- ---- --- --- --- ---- - ----
63[].south bob  workq airfoil  --   --   1  -- 0:13 Q  --
54.south bob    workq twinkie  --   --   1  -- 0:20 Q  --
```

9.6.1 Restrictions

- The two jobs must be located at the same server, and both jobs must be owned by you. However, a PBS Manager or Operator can exchange any jobs.
- A job in the running state cannot be reordered.
- The `qorder` command can be used with entire job arrays, but not on subjobs or ranges. Reordering a job array changes the queue order of the job array in relation to other jobs or job arrays in the queue.

9.7 Moving Jobs Between Queues

PBS provides the `qmove` command to move jobs between different queues (even queues on different servers). To move a job is to remove the job from the queue in which it resides and instantiate the job in another queue.

A job in the running state cannot be moved.

The usage syntax of the `qmove` command is:

qmove <destination> <job ID(s)>

Job array *<job ID>s* must be enclosed in double quotes.

The first operand is the new destination for

```
<queue>
@<server>
<queue>@<server>
```

If the *destination* operand describes only a queue, then `qmove` will move jobs into the queue of the specified name at the job's current server. If the *destination* operand describes only a server, then `qmove` will move jobs into the default queue at that server. If the *destination* operand describes both a queue and a server, then `qmove` will move the jobs into the specified queue at the specified server. All following operands are *job IDs* which specify the jobs to be moved to the new *destination*.

The `qmove` command can only be used with job array objects, not with subjobs or ranges. Job arrays can only be moved from one server to another if they are in the '*Q*', '*H*', or '*W*' states, and only if there are no running subjobs. The state of the job array object is preserved in the move. The job array will run to completion on the new server.

As with jobs, a `qstat` on the server from which the job array was moved will not show the job array. A `qstat` on the job array object will be redirected to the new server.

The subjob accounting records will be split between the two servers.

10 Checking Job & System Status

10.1 Selecting Jobs to Examine

When you want to examine jobs, you can see them all at once, or you can select a subset. You can perform this selection via the following:

- Use the qsig command to select jobs according to your criteria and return a list of job IDs, which becomes the input to the `qstat` command; see section 10.1.1, “Selecting Jobs via qselect”, on page 175
- Use options to the qstat command to filter the jobs it will display; see section 10.1.2, “Filtering Jobs via qstat”, on page 177

10.1.1 Selecting Jobs via qselect

Use the qsig command to list the job identifiers of the jobs, job arrays or subjobs that meet your selection criteria. The command prints a list of selected jobs to standard output. You can select jobs according to name, priority, project, state, etc. In this section, we describe a few ways to select jobs.

10.1.1.1 Selecting Jobs by Resource and Attribute Value

You can select jobs where attribute and/or resource values are equal to, not equal to, greater than, greater than or equal to, less than, or less than or equal to a particular value. The default relation is "equal to", specified by ".eq.".

For example, you can list the jobs owned by barry that requested more than 16 CPUs, and discover that there are three at the default server (named "south"):

```
qselect -u barry -l ncpus.gt.16
121.south
133.south
154.south
```

10.1.1.2 Selecting Jobs by Time Criteria

You can use the `qselect -t` option to list queued, running, finished and moved jobs, job arrays, and subjobs, according to values of their time attributes. You can use the `-t` option twice to bracket a time period.

Example 10-1: Select jobs with end times between noon and 3PM:

```
qselect -te.gt.09251200 -te.lt.09251500
```

Example 10-2: Select finished and moved jobs with start times between noon and 3PM:

```
qselect -x -s "MF" -ts.gt.09251200 -ts.lt.09251500
```

Example 10-3: Select all jobs with creation times between noon and 3PM:

```
qselect -x -tc.gt.09251200 -tc.lt.09251500
```

Example 10-4: Select all jobs including finished and moved jobs with qtime of 2.30PM. Here we use the default relation of ".eq". by omitting any specification for a relation:

```
qselect -x -tq09251430
```

10.1.1.3 Selecting Finished and Moved Jobs

You can list identifiers of finished and moved jobs in the same way as for queued and running jobs, as long as the job history is still being preserved. The PBS administrator sets job history preservation duration.

The -x option to the qselect command allows you to list job identifiers for all jobs, whether they are running, queued, finished or moved. The -H option to the qselect command allows you to list job identifiers for finished or moved jobs only.

To see a list of job IDs for finished and moved jobs:

```
qselect -H
```

10.1.1.4 Passing List of Selected Jobs to qstat

To see information about a selected list of job IDs, use the output of the qselect command as input to the qstat command. Syntax:

qstat [qstat options] `qselect [qselect options]`

For example, to see all queued and running jobs belonging to barry that requested more than 16 CPUs (in alternate format; see section 10.2.1.2, “Extended Job List: Job Status in Alternate Format”, on page 182):

- Linux:

```
qstat -a  `qselect -u barry -l ncpus.gt.16 `
                                                  Req'd Req'd  Elap
Job ID    User  Queue Jobname Sess NDS TSK Mem   Time S Time
--------  ----- ----- ------- ---- --- --- ---   ---- - ----
54.south  barry workq airfoil  --   --   1  --   0:13 Q   --
121.south barry workq airfoil  --   --  32  --   0:01 H   --
133.south barry workq trialx   --   --  20  --   0:01 W   --
154.south barry workq airfoil 930   --  32  --   1:30 R 0:32
```

- Windows (type the following at the cmd prompt, all on one line):

```
for /F "usebackq" %j in (`qselect -u barry -l ncpus.gt.16`) do ( qstat -a %j )
54.south
121.south
133.south
154.south
```

10.1.1.5 Passing List of Finished and Moved jobs to qstat

To use qstat to examine a list of finished or moved (history) jobs, make sure you tell both qstat via its -x option, and qselect via its -H option:

```
qstat -x  `qselect -H [qselect options] `
```

10.1.1.6 Restrictions and Caveats for Selecting Jobs via qselect

- Each time you call the qselect command, you can select jobs from just one server.
- You must use the backtick syntax to use the output of qselect as the input for qstat. You cannot use the pipe symbol to pipe output from qselect to qstat.

10.1.2 Filtering Jobs via qstat

By default, qstat displays information for queued or running jobs, not finished or moved jobs, and not job arrays or subjobs. However, you can tell `qstat` to display information for all jobs, whether they are running, queued, finished, or moved. Job history for finished and moved jobs is kept for a period defined by your administrator.

You can specify to `qstat` that you want information for a job identifier, a list of job identifiers, or all of the jobs at a destination, for example all jobs at a specified queue or server. You can get job information in three main formats:

- *Default format*: a basic table that lists each job ID on one line along with the username of the job owner, the state of the job, its queue, etc. See section 10.2.1.1, "Basic Job List: Job Status in Default Format", on page 181
- *Alternate format*: a more detailed table that lists each job ID on one line which also includes session ID, requested time, elapsed time, etc. See section 10.2.1.2, "Extended Job List: Job Status in Alternate Format", on page 182
- *Long format*: jobs are listed one at a time, and each job attribute and resource is listed on its own line. See section 10.2.1.3, "Complete Job Information: Job Status in Long Format", on page 183

10.1.2.1 Expanding and Filtering Job ID List

In addition to using `qselect` to select job IDs, you can use the following criteria:

- To see job arrays (not subjobs): `-J`
- To see job arrays and subjobs: `-t`
- To see only subjobs: `-Jt`
- To see finished and moved jobs in alternate format: `-H` ; see section 10.1.2.6.iii, "Restricting to Finished and Moved Jobs", on page 180
- To see finished and moved jobs in addition to running and queued jobs: `-x`; see section 10.1.2.6.ii, "Including Finished and Moved Jobs", on page 179

Formats for job IDs:

- Job ID:

  <sequence number>[.<server name>][@<server name>]
- Job array ID:

  <sequence number>[][.<server name>][@<server name>]
- Subjob ID:

  <sequence number>[<index>][.<server name>][@<server name>]
- Range of subjobs:

  <sequence number>[<index start>-<index end>][.<server name>][@<server name>]

  Note that some shells require that you enclose a job array identifier in double quotes.

10.1.2.2 Specifying Destination

If you don't specify a destination, you get jobs at all queues at the default server. You can specify queue and/or server. Formats for destinations:

- To display status for all jobs in the specified queue at the default server:

  <queue name>
- To display status for all jobs in the specified queue at the specified server:

  <queue name>@<server name>
- To display status for all jobs at all queues at the specified server:

  @<server name>

10.1.2.3 Filtering Jobs by User

Use the "-u" option to qstat to display jobs owned by any of a list of usernames you specify. Syntax:

qstat -u <username>[@<host>][,<username>[@<host>],...]

Host names are not required, and may be wildcarded on the left end, e.g. "**.mydomain.com*". Entering "*<username>*" without a "@*<host>*" is equivalent to "*<username>*@*".

```
qstat -u user1
                                                  Req'd  Elap
Job ID   User   Queue Jobname Sess NDS TSK Mem Time S Time
-------- ------ ----- ------- ---- --- --- --- ---- - ----
16.south user1  workq aims14   --   --   1  -- 0:01 H  --
18.south user1  workq aims14   --   --   1  -- 0:01 W  --
52.south user1  workq my_job   --   --   1  -- 0:10 Q  --

qstat -u user1,barry
                                                  Req'd  Elap
Job ID   User   Queue Jobname Sess NDS TSK Mem Time S Time
-------- ------ ----- ------- ---- --- --- --- ---- - ----
16.south user1  workq aims14   --   --   1  -- 0:01 H  --
18.south user1  workq aims14   --   --   1  -- 0:01 W  --
51.south barry  workq airfoil  930  --   1  -- 0:13 R 0:01
52.south user1  workq my_job   --   --   1  -- 0:10 Q  --
54.south barry  workq airfoil  --   --   1  -- 0:13 Q  --
```

10.1.2.4 Looking for Running and Suspended Jobs

Use the "-r" option to qstat to display the status of all running and suspended jobs in alternate format. For example:

```
qstat -r
host1:
                                        Req'd  Req'd     Elap
Job ID   User  Queue Jobname Sess NDS TSK Mem    Time  S  Time
-------- ----- ----- ------- ---- --- --- -----  ----- -  -----
43.host1 user1 workq STDIN   4693   1   1   --     --  R  00:00
```

10.1.2.5 Looking for Non-Running Jobs

Use the "-i" option to qstat to display the status of all non-running jobs (queued, held, and waiting) in alternate format. For example:

```
qstat -i
host1:
                                           Req'd  Req'd     Elap
Job ID      User  Queue Jobname Sess NDS TSK  Mem    Time   S  Time
----------  ----- ----- ------- ---- --- ---  -----  -----  -  -----
44[].host1  user1 workq STDIN     --   1   1     --     --  Q     --
```

10.1.2.6 Looking for Finished and Moved Jobs (History Jobs)

You can view information for finished and moved jobs in the same way as for queued and running jobs, as long as the job history is still being stored by PBS.

10.1.2.6.i Looking for Jobs Moved to Another Server

If your job is running at another server, you can examine it. If your site is using peer scheduling, your job may be moved to a server that is not your default server. For example, you submit a job to ServerA, and it returns the job ID as "123.ServerA". Then 123.ServerA is moved to ServerB.

- To see information about all jobs, whether running, queued, finished, or moved:

  ```
  qstat -x
  ```

- To see specific jobs, give the job ID as an argument to `qstat`:

  ```
  qstat 123
  ```

  or

  ```
  qstat 123.ServerA
  ```

- To list all jobs at ServerB:

  ```
  qstat @ServerB
  ```

Example 10-5: Viewing moved job:

- There are three servers with hostnames ServerA, ServerB, and ServerC
- barry submits job 123 to ServerA
- After some time, barry moves the job to ServerB
- After more time, the administrator moves the job to QueueC at ServerC
- barry runs "qstat 123"

```
Job id            Name         User    Time Use  S   Queue
----------------  -----------  -----   -------  ---  ------
123.ServerA       STDIN        barry   00:00:00  M   QueueC@ServerC
```

10.1.2.6.ii Including Finished and Moved Jobs

You can use the `-x` option to the `qstat` command to examine finished, moved, queued, and running jobs, in default format.

- To display information for queued, running, finished, and moved jobs, in default format:

  qstat -x

- To display information for a job, regardless of its state, in default format:

  qstat -x <job ID>

- To see status for jobs, job arrays and subjobs that are queued, running, finished, and moved:

  qstat -xt

- To see status for job arrays that are queued, running, finished, or moved

  qstat -xJ

When information for a moved job is displayed, the destination queue and server are shown as <queue>@<server>.

Example 10-6: Showing finished and moved jobs with queued and running jobs, and showing that job 102 was moved to destq at server2:

```
qstat -x
Job id            Name         User    Time Use  S   Queue
------------      -----------  ------  -------  ---  ------
101.server1       STDIN        user1   00:00:00  F   workq
102.server1       STDIN        user1   00:00:00  M   destq@server2
103.server1       STDIN        user1   00:00:00  R   workq
104.server1       STDIN        user1   00:00:00  Q   workq
```

10.1.2.6.iii Restricting to Finished and Moved Jobs

You can use the -H option to the `qstat` command to see job history for finished or moved jobs in alternate format. This does not display running or queued jobs.

- To display information for finished or moved jobs, in alternate format:

  qstat -H
- To display information for a specific job in alternate format, whether or not it is finished or moved:

  qstat -H <job ID>
- To display information for finished or moved jobs at a specific destination:

  qstat -H <destination>
- To see alternate-format status for jobs, job arrays and subjobs that are finished and moved:

  qstat -Ht
- To see alternate-format status for job arrays that are finished or moved:

  qstat -HJ

Example 10-7: Job history in alternate format:

```
qstat -H
                                                  Req'd  Req'd   Elap
Job ID  Username  Queue Jobname  SessID  NDS TSK Memory Time  S Time
------  --------  ----  -------  ------  --- --- ------ ----- -- -----
101.S1  user1     workq STDIN   5168     1  1   --     --    F  00:00
102.S1  user1     Q1@S2 STDIN    --      1  2   --     --    M   --
```

The -H option is incompatible with the `-a`, `-i`, `-f`, and `-r` options.

10.1.2.7 Grouping Jobs and Sorting by ID

You can use the -E option to sort and group jobs in the output of qstat. The -E option groups jobs by server and displays each group by ascending ID. This option also improves qstat performance. This option is useful when you have an unordered list of job IDs and you want to see ordered results grouped by server. The following table shows how the -E option affects the behavior of qstat:

Table 10-1: How -E Option Affects qstat Output

How qstat is Used	Result Without -E	Result With -E
qstat (no job ID specified)	Queries the default server and displays result	No change in behavior; same as without -E option
qstat <list of job IDs from single server>	Displays results in the order they are specified	Displays results in ascending ID order
qstat <job IDs at multiple servers>	Displays results in the order they are specified	Groups jobs by server. Displays each group in ascending order

10.2 Examining Jobs

10.2.1 How to See Job Information (Output Formats)

You can get job information in three main formats:

- *Default format*: a basic table that lists each job ID on one line along with the username of the job owner, the state of the job, its queue, etc. See section 10.2.1.1, "Basic Job List: Job Status in Default Format", on page 181
- *Alternate format*: a more detailed table that lists each job ID on one line which also includes session ID, requested time, elapsed time, etc. See section 10.2.1.2, "Extended Job List: Job Status in Alternate Format", on page 182
- *Long format*: jobs are listed one at a time, and each job attribute and resource is listed on its own line. See section 10.2.1.3, "Complete Job Information: Job Status in Long Format", on page 183

10.2.1.1 Basic Job List: Job Status in Default Format

The default qstat output format shows you a list of jobs, one to a line. Syntax:

qstat
qstat [-E] [-J] [-p] [-t] [-w] [-x] [[<job ID> | <destination>] ...]

The default display shows the following information:

- The job identifier assigned by PBS
- The job name given by the submitter
- The job owner
- The CPU time used
- The job state; see "Job States" on page 361 of the PBS Professional Reference Guide.
- The queue in which the job resides

The following example illustrates the default output format of `qstat`.

```
qstat
Job id    Name         User         Time Use S Queue
--------- ---------- ---------- -------- - -----
16.south  aims14      user1              0 H workq
18.south  aims14      user1              0 W workq
26.south  airfoil     barry       00:21:03 R workq
27.south  airfoil     barry       21:09:12 R workq
28.south  myjob       user1              0 Q workq
29.south  tns3d       susan              0 Q workq
30.south  airfoil     barry              0 Q workq
31.south  seq_35_3    donald             0 Q workq
```

10.2.1.2 Extended Job List: Job Status in Alternate Format

The alternate `qstat` output format shows you a list of jobs, one to a line, with more detail than the basic job information. Syntax:

qstat -a

qstat [-a | -H | -i | -r] [-E] [-G | -M] [-J] [-n [-1]] [-s [-1]] [-t] [-T] [-u <user list>] [-w] [[<job ID> | <destination>] ...]

The alternate format shows the following fields:

- Job ID
- Job owner
- Queue in which job resides
- Job name
- Session ID (only appears when job is running)
- Number of chunks or vnodes requested
- Number of CPUs requested
- Amount of memory requested
- Amount of CPU time requested, if CPU time requested; if not, amount of wall clock time requested
- State of job
- Amount of CPU time elapsed, if CPU time requested; if not, amount of wall clock time elapsed

```
qstat -a
                                                  Req'd  Elap
Job ID   User   Queue Jobname Ses NDS TSK Mem Time S Time
-------- ------ ----- ------- --- --- --- --- ---- - ----
16.south user1  workq aims14  --  --   1  --  0:01 H  --
18.south user1  workq aims14  --  --   1  --  0:01 W  --
51.south barry  workq airfoil 930 --   1  --  0:13 R 0:01
52.south user1  workq myjob   --  --   1  --  0:10 Q  --
53.south susan  workq tns3d   --  --   1  --  0:20 Q  --
54.south barry  workq airfoil --  --   1  --  0:13 Q  --
55.south donald workq seq_35_ --  --   1  --  2:00 Q  --
```

You can use the `-1` option to reformat `qstat` output to a single line. This option can only be used in conjunction with the `-n` and/or `-s` options.

10.2.1.3 Complete Job Information: Job Status in Long Format

The long format output of `qstat` shows you complete information about a job, including values for its attributes and resources. Syntax and example:

qstat -f
qstat -f [-F json|dsv [-D <delimiter>]] [-E] [-J] [-p] [-t] [-w] [-x] [[<job ID> | <destination>] ...]

```
qstat -f 13
Job Id: 13.host1
    Job_Name = STDIN
    Job_Owner = user1@host2
    resources_used.cpupercent = 0
    resources_used.cput = 00:00:00
    resources_used.mem = 2408kb
    resources_used.ncpus = 1
    resources_used.vmem = 12392kb
    resources_used.walltime = 00:01:31
    job_state = R
    queue = workq
    server = host1
    Checkpoint = u
    ctime = Thu Apr  2 12:07:05 2010
    Error_Path = host2:/home/user1/STDIN.e13
    exec_host = host2/0
    exec_vnode = (host3:ncpus=1)
    Hold_Types = n
    Join_Path = n
    Keep_Files = n
    Mail_Points = a
    mtime = Thu Apr  2 12:07:07 2010
    Output_Path = host2:/home/user1/STDIN.o13
    Priority = 0
    qtime = Thu Apr  2 12:07:05 2010
    Rerunable = True
    Resource_List.ncpus = 1
    Resource_List.nodect = 1
    Resource_List.place = free
    Resource_List.select = host=host3
    stime = Thu Apr  2 12:07:08 2010
    session_id = 32704
    jobdir = /home/user1
    substate = 42
    Variable_List = PBS_O_HOME=/home/user1,PBS_O_LANG=en_US.UTF-8,
        PBS_O_LOGNAME=user1,
        PBS_O_PATH=/opt/gnome/sbin:/root/bin:/usr/local/bin:/usr/bin:/usr/X11R
        6/bin:/bin:/usr/games:/opt/gnome/bin:/opt/kde3/bin:/usr/lib/mit/bin:/us
```

```
        r/lib/mit/sbin,PBS_O_MAIL=/var/mail/root,PBS_O_SHELL=/bin/bash,
        PBS_O_HOST=host2,PBS_O_WORKDIR=/home/user1,PBS_O_SYSTEM=Linux,
        PBS_O_QUEUE=workq
    comment = Job run at Thu Apr 02 at 12:07 on (host3:ncpus=1)
    alt_id = <dom0:job ID xmlns:dom0="http://schemas.microsoft.com/HPCS2008/hpcb
        p">149</dom0:Job ID>
    etime = Thu Apr  2 12:07:05 2010
    Submit_arguments = -lselect=host=host3 -- ping -n 100 127.0.0.1
    executable = <jsdl-hpcpa:Executable>ping</jsdl-hpcpa:Executable>
    argument_list = <jsdl-hpcpa:Argument>-n</jsdl-hpcpa:Argument><jsdl-hpcpa:Ar
        gument>100</jsdl-hpcpa:Argument><jsdl-hpcpa:Argument>127.0.0.1</jsdl-hp
        cpa:Argument>
```

See "Job Attributes" on page 327 of the PBS Professional Reference Guide for a description of each job attribute.

10.2.1.4 Showing Additional Job Information for Default and Alternate Formats

The long format shows everything about a job, but if you want to see your jobs in a more compact format (default or alternate), you can use the following options.

10.2.1.4.i Listing Hosts Assigned to Jobs

Use the "-n" option to qstat to display the hosts allocated to any running job, in alternate format. This shows the exec_host information immediately below the job. A text string of "--" is printed for non-running jobs. Notice the differences between the queued and running jobs in the example below:

```
qstat -n
                                                  Req'd  Elap
Job ID   User   Queue Jobname Sess NDS TSK Mem Time S Time
-------- ------ ----- ------- ---- --- --- --- ---- - ----
16.south user1  workq aims14   --   --   1  -- 0:01 H  --
 --
18.south user1  workq aims14   --   --   1  -- 0:01 W  --
 --
51.south barry  workq airfoil  930  --   1  -- 0:13 R  0:01
 south/0
52.south user1  workq my_job   --   --   1  -- 0:10 Q  --
 --
```

10.2.1.4.ii Displaying Job Comments

The "-s" option to qstat displays the job comments, in addition to the other information presented in the alternate display. The job comment is printed immediately below the job. By default the job comment is updated by the scheduler with the reason why a given job is not running, or when the job began executing. A text string of "--" is printed for jobs whose comment has not yet been set. The example below illustrates the different type of messages that may be displayed:

```
qstat -s
                                                  Req'd  Elap
Job ID   User  Queue Jobname Sess NDS TSK Mem Time S Time
-------- ----- ----- ------- ---- --- --- --- ---- - ----
16.south user1 workq aims14   --   --   1  -- 0:01 H  --
    Job held by user1 on Wed Aug 22 13:06:11 2004
18.south user1 workq aims14   --   --   1  -- 0:01 W  --
    Waiting on user requested start time
51.south barry workq airfoil  930  --   1  -- 0:13 R 0:01
    Job run on host south - started Thu Aug 23 at 10:56
52.south user1 workq my_job   --   --   1  -- 0:10 Q  --
    Not Running: No available resources on nodes
57.south susan workq solver   --   --   2  -- 0:20 Q  --
    --
```

10.2.1.4.iii Printing Job Array Percentage Completed

The "-p" option to qstat prints the default display, with a column for Percentage Completed. For a job array, this is the number of subjobs completed and deleted, divided by the total number of subjobs. For example:

```
qstat -p
Job ID           Name      User           % done  S  Queue
-------------    --------  -----------  --------  -  -----
44[].host1       STDIN     user1              40  B  workq
```

10.2.1.4.iv Viewing Job Start Time

There are two ways you can find the job's start time. If the job is still running, you can do a qstat -f and look for the stime attribute. If the job has finished, you look in the accounting log for the *S* record for the job. For an array job, only the *S* record is available; array jobs do not have a value for the stime attribute.

10.2.1.4.v Viewing Estimated Start Times For Jobs

You can view the estimated start times and vnodes of jobs using the qstat command. If you use the -T option to qstat when viewing job information, the *Elap Time* field is replaced with the *Est Start Time* field. Running jobs are shown above queued jobs. Running jobs are sorted by their stime attribute (start time).

Queued jobs whose estimated start times are unset (estimated.start_time = *unset*) are displayed after those with estimated start times, with estimated start time shown as a double dash ("--"). Queued jobs with estimated start times in the past are treated as if their estimated start times are unset.

Time displayed is local to the qstat command. Current week begins on Sunday.

If the estimated start time or vnode information is invisible to unprivileged users, no estimated start time or vnode information is available via qstat.

Example output:

```
qstat -T
                                                                  Est
                                                  Req'd  Req'd   Start
Job ID   Username Queue Jobname SessID NDS TSK Memory Time  S Time
-------  -------- ----- -------- ----- --- --- ------ ----- - -----
5.host1   user1   workq  foojob  12345  1   1  128mb 00:10  R   --
9.host1   user1   workq  foojob   --    1   1  128mb 00:10  Q  11:30
10.host1  user1   workq  foojob   --    1   1  128mb 00:10  Q  Tu 15
7.host1   user1   workq  foojob   --    1   1  128mb 00:10  Q  Jul
8.host1   user1   workq  foojob   --    1   1  128mb 00:10  Q  2010
11.host1  user1   workq  foojob   --    1   1  128mb 00:10  Q  >5yrs
13.host1  user1   workq  foojob   --    1   1  128mb 00:10  Q   --
```

If the start time for a job cannot be estimated, the start time is shown as a question mark ("?").

10.2.1.4.vi Why Does Estimated Start Time Change?

The estimated start time for your job may change for the following reasons:

- Changes to the system, such as vnodes going down, or the administrator offlining vnodes
- A higher priority job coming into the system, or a shift in priority of the existing jobs

10.2.1.5 Changing Output Format Characteristics

10.2.1.5.i Displaying Size in Gigabytes or Megawords

By default qstat displays size in the smallest displayable units. You can use the `-G` or `-M` options to `qstat` to display sizes in gigabytes or megawords, respectively. Both of these options trigger display in alternate format. If you specify `-G` and the actual size is less than 1GB, the output is rounded up to 1GB. A word is considered to be 8 bytes.

For example:

```
qstat -G
host1:
                                                Req'd  Req'd     Elap
Job ID     User  Queue Jobname Sess NDS TSK  Mem    Time   S  Time
---------  ----- ----- ------- ---- --- ---  -----  -----  -  -----
43.host1   user1 workq STDIN   4693   1   1     --     --  R  00:05
44[].host1 user1 workq STDIN     --   1   1     --     --  Q    --
45.host1   user1 workq STDIN     --   1   1    1gb     --  Q    --
```

For example:

```
qstat -M
host1:
                                                Req'd  Req'd     Elap
Job ID     User  Queue Jobname Sess NDS TSK  Mem    Time   S  Time
---------- ----- ----- ------- ---- --- ---  -----  -----  -  -----
43.host1   user1 workq STDIN   4693   1   1     --     --  R  00:05
44[].host1 user1 workq STDIN     --   1   1     --     --  Q    --
45.host1   user1 workq STDIN     --   1   1   25mw     --  Q    --
```

10.2.1.5.ii Viewing Job Status in Wider Columns

You can use the `-w qstat` option to display job status in wider columns with the default and alternate formats. The total width of the display is extended from 80 characters to 120 characters. The Job ID column can be up to 30 characters wide, while the Username, Queue, and Jobname column can be up to 15 characters wide. The SessID column can be up to eight characters wide, and the NDS column can be up to four characters wide.

You can use this option only with the `-a`, `-n`, or `-s qstat` options.

This option is different from the `-w` option used with `-f`.

10.2.1.5.iii Path Display under Windows

When you view a job in long format that was submitted from a mapped drive, PBS displays the UNC path for the job's Output_Path, Error_Path attributes, and the value for PBS_O_WORKDIR in the job's Variable_List attribute.

When you view a job in long format that was submitted using UNC paths for output and error files, PBS displays the UNC path for the job's Output_Path and Error_Path attributes.

10.2.2 Examining Job Resource Usage

10.2.2.1 Examining Resource Usage by Running and Queued Jobs

You can see resource usage by running jobs, job arrays, and subjobs, by displaying the job in long format:

```
qstat -f <job ID>
```

10.2.2.2 Examining Resources Used by Finished and Moved Jobs

You can see the resources that finished and moved jobs and job arrays have used, but not finished or moved subjobs.

10.2.2.2.i Examining Resource Usage by Finished and Moved Jobs and Job Arrays

You can see resource usage via the long format `-f` output option to `qstat`. To see the resources used by finished and moved jobs and job arrays, use the output of the `qselect` command to filter the jobs that you list via `qstat`. Tell `qstat` to look at all jobs and give you the full output showing resources in long format:

Linux:

```
qstat -fx `qselect -H`
```

Windows:

```
for /F "usebackq" %%j in (`"\Program Files\ PBSPro\ exec\ bin\qselect" -H`)
    do ("\Program Files\PBS\exec\bin\qstat" -fx %%j)
```

10.2.2.2.ii Examining Resource Usage by Finished and Moved Subjobs

Resource usage by finished and moved subjobs is available only via the accounting logs, which are available only to root and the PBS administrator.

10.2.3 Caveats for Job Information

- MoM periodically polls jobs for usage by the jobs running on her host, collects the results, and reports this to the server. When a job exits, she polls again to get the final tally of usage for that job.

  For example, MoM polls the running jobs at times T1, T2, T4, T8, T16, T24, and so on.

  The output shown by a `qstat` during the window of time between T8 and T16 shows the resource usage up to T8.

If the qstat is done at T17, the output shows usage up through T16. If the job ends at T20, the accounting log (and the final log message, and the email to you if "qsub -me" was used in job submission) contains usage through T20.

- The final report does not include the epilogue. The time required for the epilogue is treated as system overhead.
- The order in which jobs are displayed is undefined.

10.3 Checking Server Status

To see server information in default format:

qstat -B [<server> ...]

To see server information in long format:

qstat -B -f [-F json|dsv [-D <delimiter>]] [-w] [<server> ...]

10.3.0.1 Specifying Destination

If you don't specify a destination, you get the default server. You can specify a server. Format:

<server name>

Example 10-8: Getting status of non-default server S1:

```
qstat -B S1
Server      Max  Tot  Que  Run  Hld  Wat  Trn  Ext Status
----------- --- ---- ---- ---- ---- ---- ---- ---- ------
S1.example   0   14   13    1    0    0    0    0 Active
```

10.3.1 Viewing Server Information in Default Format

The "-B" option to qstat displays the status of the specified PBS server. One line of output is generated for each server queried. The three letter abbreviations correspond to the following: Maximum, Total, Queued, Running, Held, Waiting, Transiting, and Exiting. The last column gives the status of the server itself: active, idle, or scheduling.

```
qstat -B
Server      Max  Tot  Que  Run  Hld  Wat  Trn  Ext Status
----------- --- ---- ---- ---- ---- ---- ---- ---- ------
fast.domain  0   14   13    1    0    0    0    0 Active
```

10.3.2 Viewing Server Information in Long Format

You can see server status in JSON or delimiter-separated value formats; see "Job, Queue, and Server Status Options" on page 210 of the PBS Professional Reference Guide.

When querying jobs, servers, or queues, you can add the "-f" option to qstat to change the display to the *full* or *long* display. For example, the server status shown above can be expanded using "-f" as shown below:

```
qstat -Bf
Server: fast.mydomain.com
    server_state = Active
    scheduling = True
    total_jobs = 14
    state_count = Transit:0 Queued:13 Held:0 Waiting:0
        Running:1 Exiting:0
    managers = user1@fast.mydomain.com
    default_queue = workq
    log_events = 511
    mail_from = adm
    query_other_jobs = True
    resources_available.mem = 64mb
    resources_available.ncpus = 2
    resources_default.ncpus = 1
    resources_assigned.ncpus = 1
    resources_assigned.nodect = 1
    scheduler_iteration = 600
    pbs_version = PBSPro_2022.1.41640
```

10.4 Checking Queue Status

To view queue information in default format:

qstat -Q [<destination> ...]

To view queue information in alternate format:

qstat -q [-G | -M] [<destination> ...]

To view queue information in long format:

qstat -Q -f [-F json|dsv [-D <delimiter>]] [-w] [<destination> ...]

10.4.1 Specifying Destination

If you don't specify a destination, you get jobs at all queues at the default server. You can specify queue and/or server.

- To display status for the specified queue at the default server:
  <queue name>
- To display status for the specified queue at the specified server:
  <queue name>@<server name>
- To display status for all queues at the specified server:
  @<server name>

10.4.2 Viewing Queue Information in Default Format

The "-Q" option to qstat displays the status of specified queues. One line of output is generated for each queue queried.

```
qstat -Q
Queue Max Tot Ena Str Que Run Hld Wat Trn Ext Type
----- --- --- --- --- --- --- --- --- --- --- ---------
workq   0  10 yes yes   7   1   1   1   0   0 Execution
```

The columns show the following for each queue:

- Queue Queue name
- Max Maximum number of jobs allowed to run concurrently in the queue
- Tot Total number of jobs in the queue
- Ena Whether the queue is enabled or disabled
- Str Whether the queue is started or stopped
- Que Number of queued jobs
- Run Number of running jobs
- Hld Number of held jobs
- Wat Number of waiting jobs
- Trn Number of jobs being moved (transiting)
- Ext Number of exiting jobs
- Type Type of queue: execution or routing

10.4.3 Displaying Queue Limits in Alternate Format

The "-q" option to qstat displays any limits set on the requested (or default) queues. Since PBS is shipped with no queue limits set, any visible limits will be site-specific. The limits are listed in the format shown below.

```
qstat -q
server: south

Queue  Memory CPU Time Walltime Node Run Que Lm  State
------ ------ -------- -------- ---- --- --- --  -----
workq    --      --       --     --    1   8 --   E R
```

10.4.4 Viewing Queue Information in Long Format

You can see queue information in JSON or delimiter-separated value formats; see "Job, Queue, and Server Status Options" on page 210 of the PBS Professional Reference Guide.

Use the long format to see the value for each queue attribute:

```
qstat -Qf
Queue: workq
    queue_type = Execution
    total_jobs = 10
    state_count = Transit:0 Queued:7 Held:1 Waiting:1
        Running:1 Exiting:0
    resources_assigned.ncpus = 1
    hasnodes = False
    enabled = True
    started = True
```

10.4.5 Caveats for the `qstat` Command

When you use the `-f` option to `qstat` to display attributes of jobs, queues, or servers, attributes that are unset may not be displayed. If you do not see an attribute, it is unset.

10.5 Checking License Availability

You can check to see where licenses are available. You can do either of the following:

- Display license information for the current host:
  ```
  qstat -Bf
  ```
- Display resources available (including licenses) on all hosts:
  ```
  qmgr
  Qmgr: print node @default
  ```

If your site is using floating licenses, when looking at the server's license_count attribute, use the sum of the *Avail_Global* and *Avail_Local* values.

11 Running Jobs in the Cloud

11.1 Introduction

You run a job in the cloud by putting that job in a cloud queue. You can submit the job to the queue, or move it there from another queue. Each cloud queue gives its jobs access to a specific scenario; that scenario offers specific instance types, OS images, and application licenses. Each scenario has a default instance type and OS image. Each job can request any instance type, OS image, or application license offered by the scenario. A job cannot request an instance type, OS image, or application license that is not offered by the scenario.

11.2 Running Your Job in the Cloud

Each cloud scenario is associated with a specific cloud queue and vice versa. Each scenario offers specific instance types, OS images, and application licenses. Submit your job to the cloud queue that offers the right combination. You specify the queue via the `-q <queue name>` option to `qsub`. You can override the default instance type and OS image by requesting them at job submission.

To submit a job that can run in the cloud, submit it to the configured cloud queue. Syntax:

qsub -q <name of cloud queue> -l <resource request> <job script>

For example:

```
qsub -q cloudq -- /bin/sleep 100
```

11.2.1 Requesting Instance Type

Each scenario has a default instance type, specified in the cloud_instance_type queue resource. You can choose any of the instance types offered by the queue scenario. To request an instance type, specify the instance via the cloud_node_instance_type chunk resource:

qsub -lselect=...:cloud_node_instance_type=<instance type>:... -q <queue name> <job script>

For example:

```
qsub -lselect=1:ncpus=2:mem=1gb:cloud_node_instance_type=e2-highmem-8
```

Make sure that the instance type you request matches the offered instance type exactly. Each chunk can request or default to a different instance type.

11.2.1.1 Requesting Preemptable and Spot Instances

If the scenario includes them, you can request preemptable instances, including spot instances. When requesting cloud nodes, the request should be for either non-preemptable instances or preemptable instances, but not both. Do not request some cloud nodes that are on-demand and some that are preemptable or spot.

11.2.2 Requesting OS Image

Each scenario has a default OS image, specified in the cloud_default_image scenario parameter. You can use the default, or choose any of the OS images offered by the queue scenario. To request an OS image, specify the image via the cloud_node_image chunk resource in the select statement.

qsub -lselect=...:cloud_node_image=<OS image>:... -q <queue name> <job script>

For example:

```
qsub -lselect=1:ncpus=2:mem=1gb:cloud_node_image="myimages/image-1" myscript
```

Each chunk can use a different OS image.

11.2.3 Running Your Job on Cloud Nodes Connected by a High Speed Network

You may want to run jobs on cloud nodes where all job nodes are on the same high speed network. Cloud providers can allow PBS Cloud to burst groups of nodes where each group is connected by a high speed switch. For example, Azure provides InfiniBand *scale sets*, and Oracle provides InfiniBand *instance pools*. To simplify the discussion, we call a group of nodes on a high speed network a *proximate node group*.

When PBS Cloud bursts a group of nodes on a high speed network, it labels all of the nodes in that proximate node group with the same network name. You do not need to request the actual network name; you only need to request that your job is on such a node group via the `cloud_network=ib` chunk request. See our example below.

11.2.3.1 Running Your Job on Cloud Instances Connected by a High Speed Network and Burst on Bare Metal

Additionally, PBS lets you run jobs on cloud nodes connected by a high speed network where the instances are burst on bare metal. There is no difference between running a job on a high speed network with or without using bare metal. To burst instances on bare metal, make sure that you choose the correct instance type and matching OS (but this is true for any job using a high speed network).

In this version, Oracle is the only provider that allows you to burst instances on bare metal.

11.2.3.2 Caveats and Restrictions for Jobs on High Speed Networks

You can run your job using a high speed network only where the network is offered by the cloud provider and supported by PBS Cloud. Currently PBS Cloud supports high speed networks on Oracle and Azure.

The current default limit for the number of Azure nodes with InfiniBand is *100*.

11.2.3.3 How to Run a Job on Cloud Nodes on a High Speed Network

To run on a group of cloud nodes connected by a high speed network (a proximate node group), request `cloud_network=ib` for each job chunk. O

Make sure that each chunk in your job gets the following, and make sure they are the same across all chunks of the job:

- Instance type with high speed network enabled

  via the cloud_node_instance_type resource
- OS image enabled with a high speed network

  via the cloud_node_image resource

You can submit your job to the queue that is associated with the bursting scenario you want that has the instance type and OS image you want (for example, an Azure scenario with InfiniBand enabled). You can also request the instance type and OS image.

Here is the syntax for running your job in a proximate node group and requesting instance type and OS image:

qsub -q <cloud queue> -lselect=...:cloud_network=ib:cloud_node_instance=<instance type w/high speed network>:cloud_node_image=<OS image w/high speed network> <job script>

For example:

```
qsub -q cloudq -lselect=1:ncpus=2:mem=1gb:cloud_network=ib:cloud_node_instance_type= e2-high-mem-8:cloud_node_image="projects/images/myimage" -- /bin/sleep 60
```

Do not request the cloud_scenario resource.

11.2.4 Running Jobs Requiring Application Licenses

To run a job that needs an application license:

- Choose a scenario that offers that application license
- Request the application license

  Each application license is represented by two PBS resources; one is static, and one is dynamic. If your job requires an application license, your job script must include requests for both resources. For example, if your job requires an App1 license, represented by the resources app1_static and app1_dynamic, your job script should contain the following:

```
#PBS -l app1_static=1
#PBS -l app1_dynamic=1
```

11.3 Sample Job Scripts for Cloud Jobs

11.3.1 Example of Simple Sleep Job Script

Example 11-1: Simple job requesting 10 minutes of walltime that will sleep for 1 minute (or tune $sleeptime as appropriate) and then exit. It requests *cloudq*; adjust the name depending on your site configuration. You can save the following job script as `sleep.sh`. Then you can submit it to PBS:

```
qsub sleep.sh
```

Script:

```
#!/bin/bash
#PBS -N testjob
#PBS -j oe
#PBS -m n
#PBS -q cloudq
#PBS -l select=1:ncpus=2:mem=16mb
#PBS -l walltime=0:10:00
sleeptime=60
cmd="sleep $sleeptime"
echo $cmd
$cmd
exit
```

11.3.2 Example of Radioss Cloud Job Script

Example 11-2: Job script for cloud job that uses 25 Radioss licenses. This script uses Intel MPI. The static resource is named "Rad_stat" and the dynamic resource is named "Rad_dyn":

```
#!/bin/bash
#PBS -N RunRad
#PBS -j oe
#PBS -m n
#PBS -q CloudRadq
#PBS -P project1
#PBS -l select=1:ncpus=16:mem=16gb
#PBS -l walltime=2:00:00
#PBS -l Rad_stat=25
#PBS -l Rad_dyn=25
/usr/local/altair/scripts/radioss -mpi i -nt $NCPUS -np 1 -hostfile $PBS_NODEFILE -both
   SEAT_DYREL_0000.rad
```

11.3.3 Viewing Job Output

When the job completes you should see the job's output. This will appear where the job was submitted.

12 Using Budgets

12.1 Budgets Commands

12.1.1 Command Path

To run Budgets commands, export the path of the am binaries to the PATH environment variable by using the command:

```
export PATH=$PATH:/opt/am/python/bin/
```

12.1.2 Using Budgets Commands

All Budgets commands are prefixed with "amgr ".

To see a list of Budgets subcommands with a single-line description for each command:

```
amgr <enter>
```

To get usage information for a command or subcommand:

<*command*> *--help*

<*command*> <*subcommand*> *--help*

For example:

`amgr add --help` provides information on how to use the main `amgr add` command

`amgr add period --help` provides information on how to use the `period` subcommand.

If you enter a command without the required arguments, Budgets will prompt you to enter them.

See "Budgets Commands" on page 77 in the PBS Professional Budgets Guide.

12.2 Submitting Jobs with Budgets

Before you submit a job, you can ask Budgets to give you an estimate for the cost of the job.

Any job that is submitted must be validated by Budgets in order to be queued. Make sure that you are charging the job to a valid user or project account.

You can run project jobs on the PBS complexes associated with the project. You can run your own jobs on the complexes associated with your account. You can run jobs only when your account is active.

Job submitters do not need to log into Budgets.

12.2.1 Getting Job Cost Estimate from Budgets

You can get Budgets to give you a quote for the cost of your job before you submit that job. It can tell you how much of each currency the job would require if you were to submit the job. You request an estimate, then PBS prints the estimated costs associated with the job. You can get cost estimates for cloud or on premise jobs.

Estimated cost may be different from actual cost because Budgets estimates the cost of each job based on the job's requested resources, but computes the final cost for a job that has run based on resources actually used.

If your administrator has configured Budgets with the `quote` command, you can use that to get a job quote. Otherwise you use the `qsub` command to get a job quote. When you use the `qsub` command to get a quote, you use normal job submission language, but the job does not actually run.

12.2.1.1 Requesting Cost Estimate via quote Command

To use the `quote` command to get an estimate for the cost of a job, you use the same job script or resource request as you would to submit the job, but you pass it to the `quote` command:

quote <job script>

quote -l <resource>=<value> -lselect=...

For example:

```
quote my_job_script.sh
quote -l walltime=1:00 -lselect=2:ncpus=4:mem=8GB --/bin/sleep 30
```

12.2.1.1.i Examples of Requesting Estimate of Costs via quote Command

Example 12-1: You submit a sleep job requesting 30 seconds of walltime and your sleep command calls for 30 seconds, and the charge rate is a penny for every CPU-second:

```
quote -l walltime=30 --/bin/sleep 30
qsub: Budgets estimate for job cost: {"cpu_sec": 30.0, "dollar": 0.30}
```

If you run the job, you are charged 30 cents (one penny for each CPU-second).

Example 12-2: You submit a sleep job requesting 30 seconds of walltime but your sleep command calls for 20 seconds, and the charge rate is a penny for every CPU-second:

```
quote -l walltime=30 --/bin/sleep 20
qsub: Budgets estimate for job cost: {"cpu_sec": 30.0, "dollar": 0.30}
```

If you run the job, you are charged 20 cents (one penny for each CPU-second).

12.2.1.2 Requesting Cost Estimate via qsub Command

To use the `qsub` command to get an estimate for the cost of a job, you use the same `qsub` command to submit the job, but you include "`-l am_job_quote=true`":

```
qsub ... -l am_job_quote=true
```

When you include this option, the job is not actually submitted, only evaluated.

12.2.1.3 Estimate Format

Budgets prints an estimate for the amount of each currency your job would require. Format:

qsub: Budgets estimate for job cost: {"<currency name>": <value>, "<currency name>": <value>, ...}

12.2.1.3.i Examples of Requesting Estimate of Costs via qsub Command

Example 12-3: You submit a sleep job requesting 30 seconds of walltime and your sleep command calls for 30 seconds, and the charge rate is a penny for every CPU-second:

```
qsub -l walltime=30 -l am_job_quote=t --/bin/sleep 30
qsub: Budgets estimate for job cost: {"cpu_sec": 30.0, "dollar": 0.30}
```

If you run the job, you are charged 30 cents (one penny for each CPU-second).

Example 12-4: You submit a sleep job requesting 30 seconds of walltime but your sleep command calls for 20 seconds, and the charge rate is a penny for every CPU-second:

```
qsub -l walltime=30 -l am_job_quote=t --/bin/sleep 20
qsub: Budgets estimate for job cost: {"cpu_sec": 30.0, "dollar": 0.30}
```

If you run the job, you are charged 20 cents (one penny for each CPU-second).

12.2.1.4 Caveats and Restrictions for Getting Job Cost Estimate

Some nodes may have special costs associated with those nodes. Budgets does not know where the job will run, so it does not know about costs associated with specific nodes. The estimate you get from Budgets will not include those costs, if any.

12.2.2 Checking Whether You Have Enough Credit to Run Job

You can query Budgets to find out whether you have sufficient credit to run a specific job or jobs. Note that you can give the command a list of jobs to check; the command examines each job individually, without considering the other jobs in the list. So for example if you have 10 credits, and you check two jobs each requiring 10 credits, the command will tell you that you can run both. To query Budgets about jobs, use `amgr precheck jobs`. See "Prechecking Jobs" on page 126 in the PBS Professional Budgets Guide.

12.2.3 Charging Jobs to User or Project Account

When you submit a job, the job is charged to an account.

- To charge a job to a project account, use `qsub -P <project name>` to specify the project. For example, to run a job using ProjectScript for one hour and charge it to the project named "Project1":

  ```
  qsub -P Project1 -l select=1:ncpus=1:mem=1gb -l walltime=1:00:00 ProjectScript
  ```

- To charge a job to your own account, do not specify a project. For example, to run a job using MyScript for one hour and charge it to your own account:

  ```
  qsub  -l select=1:ncpus=1:mem=1gb -l walltime=1:00:00 MyScript
  ```

12.2.4 Credit

Each project has its own credit balance, and each job submitter has their own credit balance. Credit is measured in standard service units. A service unit represents usage of a PBS-tracked resource, such as CPU hours or GPU hours. A service unit can be treated like a currency. Group managers are responsible for depositing service units into user and project accounts.

12.2.5 Submitting Jobs in Postpaid Mode

In postpaid mode, you do not need credit to run a job. Running jobs in postpaid mode is like using a credit card, except that the amount you can charge is not limited by Budgets and you don't have to pay off the bill.

If you are in postpaid mode, you can charge jobs to your own account or any project accounts to which you belong.

When a job finishes, Budgets debits the amount of credit that was consumed by the job.

You can optionally pay down the bill, and the administrator can optionally refund you for a job.

12.2.6 Submitting Jobs in Prepaid Mode

In prepaid mode, you need credit in order to run a job.

If you are in prepaid mode, you can charge jobs to your own account as long as you have sufficient credit. If you are part of a project, you can charge project jobs to that project's account, as long as the project has sufficient credit.

You can start a job only if the credit account it will use has sufficient credit. When the job starts, the requested credit is put into escrow. When the job finishes, any unused credit is returned to the account. Budgets does not allow your credit balance to become negative.

If you do not have sufficient credit to run a job, the job is held with a *user* hold. To allow the job to run, first acquire enough credit to run the job, then use qrls to release the hold on the job.

12.2.7 Resource Requirements for Jobs

Each job must request the compute resources that are used in the billing formula used at that complex. For the default formula, this means walltime and ncpus. Make sure that every PBS job requests ncpus and walltime when it runs. Each job can have these set at submission by the job submitter or later via `qalter`, can inherit a value from the server or queue, or can be assigned a value by a hook. For ncpus, the server attribute default_chunk.ncpus may take care of the requirement.

12.2.8 Accounting Policy

Jobs are charged to the periods in which they run. A project job is charged according to the project's accounting policy. Your jobs are charged according to your accounting policy. An accounting policy is one of the following:

begin_period
: The user or project account is charged when the job begins.

end_period
: The user or project account is charged when the job ends.

proportionate
: The user or project account is charged during all periods when the job runs, and each period is charged in proportion to the usage during that period.

12.2.9 Allocation Periods

Your credit balance is allocated in specific time periods. Each period has a defined start and end date.

To see what periods have been defined:

```
amgr ls period
```

See "Listing Periods" on page 88 in the PBS Professional Budgets Guide.

In prepaid mode, credit in a period cannot be used when the period is over, although a group manager or administrator can transfer credit from one period to another.

12.2.10 Checking Your Credit Balance

When you check your credit balance, specify the period:

amgr checkbalance -n <your username> -p <period>

For example, if your username is MyUsername and the period in question is Q4:

```
amgr checkbalance -n MyUsername -p Q4
```

See "Checking Service Unit Balance for User" on page 122 in the PBS Professional Budgets Guide.

12.2.11 Listing Clusters

You can list the clusters that represent PBS complexes associated with Budgets:

amgr ls cluster [-n <PBS server>] [-a <active>] [-f] [-l | -j]

For example:

```
amgr ls cluster -n Cluster1 -f
```

See "Listing Clusters" on page 87 in the PBS Professional Budgets Guide.

12.2.12 Quotas on External Resources

There may be quotas set on externally-managed resources such as storage. A quota is a limit on a dynamic service unit. To see quotas, list all service units:

```
amgr ls serviceunit
```

See "Listing Service Units" on page 88 in the PBS Professional Budgets Guide.

12.2.13 Getting Reports on Usage and Transactions

You can get reports on your own usage:

amgr report user -n <username> [-s <service unit name> | -t <service unit type>] -h <group names> -p <period> -S <start date> -E <end date> [-l] [-o <output file>] [-r]

For example, to get a report on MyUsername for the period Q4:

```
amgr report user -n MyUsername -p Q4
```

See "Getting User Reports" on page 104 in the PBS Professional Budgets Guide.

You can get reports on your transactions

amgr report transaction -i <transaction ID> [-l] -N <count> [-o <output-file>] [-r]

12.3 Tutorials

12.3.1 Tutorial on Using Budgets in Prepaid Mode

12.3.1.1 Prerequisites

A working installation of PBS Professional, with at least two accounts that can submit and run jobs at the complex. In our example, the cluster is named Cluster1, and the users are User1 and User2. User1 is associated with a cluster named Cluster1 and a project named P1. User1 has credit of 1200 cpu_hrs, and P1 has credit of 1000 cpu_hrs.

Substitute in your own names for the cluster, project, and users when going through the tutorial.

12.3.1.2 Tutorial Steps to Use Budgets

12.3.1.2.i Run User Job

1. Log in as User1.
2. Run a sleep job for 10 seconds with a walltime of 2 minutes, and charge it to user User1:

   ```
   qsub -lwalltime=00:02:00 -- /bin/sleep 10
   ```

3. Check the credit balance for user User1. It will have decreased:

   ```
   amgr checkbalance user -n User1 -p 2022.Q2
   ```

4. After the job is finished, check the balance again. You should see that the unused amount has been returned:

   ```
   amgr checkbalance user -n User1 -p 2022.Q2
   ```

12.3.1.2.ii Run Project Job

5. Run a sleep job for 36 seconds with a walltime of 1 hour, and charge it to project P1:

   ```
   qsub -P P1 -lwalltime=01:00:00 -- /bin/sleep 36
   ```

6. To see the job running:

   ```
   qstat -sw
   ```

7. Log in as Manager1.
8. Check the credit balance for project P1. It will have decreased:

   ```
   amgr checkbalance project -n P1 -p 2022.Q2
   ```

9. After the job is finished, check the balance again. You should see that the unused amount has been returned:

   ```
   amgr checkbalance project -n P1 -p 2022.Q2
   ```

12.3.1.2.iii Non-project User Tries to Run Project Job

10. Log in as User2.
11. Run a sleep job for 10 seconds with a walltime of 2 minutes, and charge it to user User2:

    ```
    qsub -lwalltime=00:02:00 --/bin/sleep 10
    ```

12. Check the credit balance for user User2. It will have decreased:

    ```
    amgr checkbalance user -n User2 -p 2022.Q2
    ```

13. After the job is finished, check the balance again. You should see that the unused amount has been returned:

    ```
    amgr checkbalance user -n User2 -p 2022.Q2
    ```

14. Run a sleep job for 10 seconds with a walltime of 2 minutes, and charge it to project P1:

    ```
    qsub -P P1 -lwalltime=00:02:00 -- /bin/sleep 10
    ```

    This job cannot run, because User2 is not part of project P1.

Example 12-5: Report for all standard service units and current lowest period:

```
amgr report project -n p1
```

12.3.1.2.iv Manager Runs Report on Project

15. Log in as Manager1:

    amgr login

16. Get report on project P1:

    amgr report project -n P1

    Command output:

```
--------------------------------------------------------------------------
name | period   | serviceunit | opening_balance | total_credits
--------------------------------------------------------------------------
P1   | 2022     | cpu_hrs     | 0.0             | 1000.0

--------------------------------------------------------------------------
| total_debits | total_debits_reconciled | total_debits_authorized
--------------------------------------------------------------------------
| 0.01         | 1.99                    | 0.0

-------------------------
| net_balance | metadata
-------------------------
| 999.99      | {}
```

12.3.2 Tutorial on Using Budgets in Postpaid Mode

12.3.2.1 Prerequisites

A working installation of PBS Professional, with at least two accounts that can submit and run jobs at the complex. In our example, the cluster is named Cluster1, and the users are User1 and User2. User1 is associated with a cluster named Cluster1 and a project named P1.

Substitute in your own names for the cluster, project, and users when going through the tutorial.

12.3.2.2 Tutorial Steps to Use Budgets

12.3.2.2.i Run User Job

17. Log in as User1.

18. Run a sleep job for 10 seconds with a walltime of 2 minutes, and charge it to user User1:

    qsub -lwalltime=00:02:00 -- /bin/sleep 10

19. After the job is finished, check the credit used by user User1. It will have increased:

    amgr checkbalance user -n User1 -p 2022

12.3.2.2.ii Run Project Job

20. Run a sleep job for 36 seconds with a walltime of 1 hour, and charge it to project P1:

```
qsub -P P1 -lwalltime=01:00:00 -- /bin/sleep 36
```

21. To see the job running:

```
qstat -sw
```

22. Log in as Manager1.
23. After the job is finished, check the credit used by project P1. It will have increased:

```
amgr checkbalance project -n P1 -p 2022
```

12.3.2.2.iii Non-project User Tries to Run Project Job

24. Log in as User2.
25. Run a sleep job for 10 seconds with a walltime of 2 minutes, and charge it to user User2:

```
qsub -lwalltime=00:02:00 --/bin/sleep 10
```

26. After the job is finished, check the credit used by user User2. It will have increased:

```
amgr checkbalance user -n User2 -p 2022
```

27. Run a sleep job for 10 seconds with a walltime of 2 minutes, and charge it to project P1:

```
qsub -P P1 -lwalltime=00:02:00 -- /bin/sleep 10
```

This job cannot run, because User2 is not part of project P1.

12.3.2.2.iv Manager Runs Report on Project

28. Log in as Manager1:

```
amgr login
```

29. Get report on project P1:

```
amgr report project -n P1
```

Command output:

```
-------------------------------------------------------------------------
name    | period   | serviceunit   | total_outstanding   | metadata
-------------------------------------------------------------------------
P1      | 2022     | cpu_hrs       | 000.01              | {}
```

13 Submitting Jobs to NEC SX-Aurora TSUBASA

13.1 Vnodes for NEC SX-Aurora TSUBASA

The basic hardware unit for NEC SX-Aurora TSUBASA is a *vector host* (a standard x86 server) connected to a set of accelerators called *vector engines* (VEs) via optional PCIe. The unit can consist of one or more NUMA nodes. Each unit uses one or more host channel adapters to communicate with other units and with the rest of the world.

The increasing order of communication overhead is first within a vector engine, then between vector engines via a shared PCIe, then between vector engines via PCIes on a common vector host, and finally between vector engines on separate vector hosts.

PBS creates topology-aware vnodes by grouping each PCIe with its associated vector host and vector engines together into one vnode. If there is no PCIe, PBS groups the vector host and its VEs into a vnode. A NUMA node without its own PCIe is in its own vnode. The topology-based vnode creation is handled by an exechost_startup event in the built-in hook named PBS_sx_aurora.

PBS tries to do topology-aware scheduling by grouping job processes on vector engines in a way that produces the lowest communication overhead. When a job requests vector engines, PBS tries to assign vector engines from a single vnode to minimize communication overhead between vector engines.

13.2 Terminology

HCA

Host channel adapter. Network interconnect used by vnode. Each vector host can have one or more HCAs.

Vector engine, VE

Accelerator associated with vector host. Executes parallel and/or vectorized numeric operations.

Vector host, VH

Standard x86 server. Performs tasks such as I/O.

VE offloading

Main operations that take place on the vector host offload parallel and/or vectorized numeric operations to vector engines. In offloading, NEC MPI launches processes on the VH, and those processes then launch other job processes on VEs assigned to the job. See section 13.4.3.4, “Using VE Offloading”, on page 210.

13.3 Resources for SX-Aurora TSUBASA

nves

Host-level consumable integer. Allows you to specify the number of vector engines per chunk. PBS sets the available VEs on a vnode in resources_available.nves. The default for resources_available.nves is number of VEs attached to the PCIe. The out-of-the-box default value for a job request is zero; PBS assigns a value of zero unless the administrator has set the value otherwise.

nhcas

Chunk-level non-consumable integer. When requested in a job chunk, PBS sets _NEC_HCA_LIST_IO and _NEC_HCA_LIST_MPI environment variables accordingly for that chunk. When not requested for a chunk, PBS sets _NEC_HCA_LIST_IO and _NEC_HCA_LIST_MPI to include all HCAs on a host.

ve_mem

Job-wide string. Used for reporting the maximum memory on vector engines used by job.

ve_cput

Job-wide string. Used for reporting the total CPU time, in seconds, on vector engines used by job.

ncpus

PBS sets the value of resources_available.ncpus on each vnode to (#CPUs on whole host / #vnodes on host) - #VEs on vnode. One CPU per VE is reserved for the VEOS daemon.

mem

PBS sets the value of resources_available.mem on each vnode by dividing the memory of the whole host equally among the vnodes on the host.

13.4 Running Your Job on NEC SX-Aurora TSUBASA

13.4.1 Requesting Resources on NEC SX-Aurora TSUBASA

You can request CPUs on the VH using the ncpus resource. If you do not request ncpus for the processes that will run on the VH, PBS will assign your job the default number of CPUs, which is generally 1 (one).

You request VEs for each chunk using the nves resource.

You request HCAs for each chunk using the nhcas resource. PBS will always try to assign the HCA closest to the job's VEs to the job.

13.4.1.1 Restrictions for Requesting HCAs

If you request chunks with different numbers of HCAs, for example a one-HCA chunk and a two-HCA chunk, add `-l place=scatter` to your request, otherwise performance may be reduced. If you do not specify `-l place=scatter`, the value of nhcas for all chunks on each vector host is set to the value given for the first chunk.

13.4.2 Default Process Distribution

On NEC SX-Aurora TSUBASA, use the mpirun command and optionally specify process distribution via the NEC_PROCESS_DIST environment variable. NEC MPI launches processes directly on VHs and/or VEs and orders process ranks according to the mpirun command line. Here are some example mpirun commands that use default process distribution:

Example 13-1: To run 32 ve.out processes on VEs:

```
mpirun -np 32 ve.out
```

Example 13-2: To run 1 vh.out process on the VH and 12 ve.out processes on VEs:

```
mpirun -vh -np 1 vh.out : -np 12 ve.out
```

The process with rank 0 executes vh.out on a VH, and processes with ranks 1 through 12 execute ve.out on VEs.

Example 13-3: We have 1 chunk with 4 VEs running 4 processes, and 1 chunk with 4 VEs running 13 processes:

```
qsub -lselect=1:nves=4:mpiprocs=4+1:nves=4:mpiprocs=13
```

In job script:

```
mpirun -np 17 ve.out
```

13.4.2.1 Letting PBS Distribute VE Processes in a Chunk

Without NEC_PROCESS_DIST, PBS distributes processes in a chunk as described in this section, depending on whether or not the number of processes in the chunk is an integer multiple of the number of VEs in the chunk. Processes are directly launched by NEC MPI. When it is an integer multiple, we call it "perfect distribution".

13.4.2.1.i Perfect Distribution

Within a chunk, if the number of processes is an integer multiple of the number of VEs, PBS puts the same number of processes on each VE. For example if you have 12 processes and 4 VEs, PBS puts 3 processes on each VE.

To let PBS distribute VE processes as evenly as possible across the VEs in a chunk, request the chunk, and specify the number of VEs and the number of processes via the mpiprocs resource.

Example 13-4: We have 1 chunk with 6 processes and 2 VEs, and we want 3 VE processes to run on each VE:

In the job script:

```
mpirun -np 6 ve.out
```

Submit the job:

```
qsub -l select=ncpus=2:nves=2:mpiprocs=6 ...
```

13.4.2.1.ii Imperfect Distribution

If the number of processes is not an integer multiple of the number of VEs, PBS gives more processes to the VEs earlier in topological order as recognized by PBS. PBS gives those VEs the smallest integer greater than (#processes / #VEs), and puts the remainder on the next VE. For example if you have 10 processes and 4 VEs, PBS may put 3 processes on the first 3 VEs, and one process on the last VE. However, if you have 5 processes and 4 VEs, PBS puts 2 processes on the first 2 VEs, 1 process on the next VE, and no processes on the last VE.

Example 13-5: We request 2 CPUs, 3 VEs, and 8 mpiprocs. In this example, the first VE gets 3 VE processes, the second VE gets 3 VE processes, and the third VE gets 2 processes. In the job script:

```
mpirun -np 8 ve.out
```

Submit the job:

```
qsub -l select=ncpus=2:mpiprocs=8:nves=3 ...
```

Distribution of processes on VEs:

```
ve=0
ve=0
ve=0
ve=1
ve=1
ve=1
ve=2
ve=2
```

13.4.3 Specifying Process Distribution

You can optionally use the NEC_PROCESS_DIST environment variable to specify where processes should run. You specify process distribution chunk by chunk. You can either launch processes directly via NEC MPI, or you can have the process(es) that run on the VH launch any processes that run on VEs.

In each chunk, you can do the following:

- Specify the number of processes for each VE in the chunk, using one of these methods:
  - Specify different numbers of processes for direct launch on each VE, as in Section 13.4.3.1, "Specifying Process Placement for All VEs in a Chunk"
  - Distribute processes for direct launch evenly by specifying the number of processes for just the first VE and implying the rest, as in Section 13.4.3.2, "Replicating Process Distribution Across VEs in a Chunk"
  - Let PBS distribute the processes for direct launch as evenly as possible, as in Section 13.4.2.1, "Letting PBS Distribute VE Processes in a Chunk"
  - Use VE offloading to indirectly launch processes on VEs, as in Section 13.4.3.4, "Using VE Offloading"
- Specify which processes should run on the vector host, as in Section 13.4.3.3, "Placing Processes on VHs"

Additionally, if you have a group of identical chunks, you can specify the process placement for the first of these chunks, and PBS can replicate the placement for the remaining identical chunks. If you have more than one such group, where each group is different, you can specify the placement for just the first chunk for each group. See Section 13.4.3.5, "Replicating the Same Process Distribution Across Multiple Chunks".

We describe the syntax for process distribution in detail in each of the following sections, but here is a summary. Syntax for process distribution for multiple chunks:

NEC_PROCESS_DIST = <chunk1 distribution>+<chunk2 distribution> +... + <chunkN distribution>

where *<chunk distribution>* is

[<number of processes on vector host>]:[<number of processes on first VE>][:<numbers of processes on subsequent VEs>]

Separate each chunk specification using a plus sign ("+").

13.4.3.1 Specifying Process Placement for All VEs in a Chunk

Within each chunk, you can optionally specify how many VE processes should be directly launched by NEC MPI on each VE. Separate the number of VE processes you want on each VE with a colon.

Syntax for distribution of processes on VEs in a single chunk:

NEC_PROCESS_DIST=<process count for first VE>:<process count for second VE> :...: <process count for nth VE>

Example 13-6: We have 6 processes, and 3 VEs, and we want 1 process to run on the first VE, 3 on the second, and 2 on the third:

```
qsub -lselect=1:ncpus=2:nves=3:mpiprocs=6 -v NEC_PROCESS_DIST=1:3:2
```

13.4.3.1.i Restrictions and Caveats for Process Placement for All VEs in Chunk

For a chunk, when you specify the process count for more than one VE, you must specify the process count for all VEs.

13.4.3.2 Replicating Process Distribution Across VEs in a Chunk

If you specify how many VE processes should be directly launched by NEC MPI on just the first VE in a chunk, PBS can replicate that distribution for the rest of the VEs in the chunk. Distribution depends on whether or not the number of processes in the chunk is an integer multiple of the number of VEs in the chunk. When it is an integer multiple, we call it "perfect distribution". We say that when you specify only for the first VE in a chunk, you are *implying* what should happen for the others in that chunk.

Syntax for replicating process distribution across VEs in a single chunk:

NEC_PROCESS_DIST=<process count for first VE>

13.4.3.2.i Implying Perfect Distribution

You can use implied specification for perfect distribution via direct launch by NEC MPI over VEs.

Example 13-7: We have 1 chunk with 6 processes and 2 VEs, and we want 3 VE processes to run on each VE:

```
-l select=ncpus=2:nves=2:mpiprocs=6 -v NEC_PROCESS_DIST=3
```

13.4.3.2.ii Implying Imperfect Distribution

You can imply imperfect distribution (when the number of processes is not an integer multiple of the number of VEs) via direct launch by NEC MPI, by following the same formula PBS uses. Specify the larger number of processes (the smallest integer greater than #processes/#VEs) for the first VE. For example, if you have 7 processes and 3 VEs, specify 3 processes for the first VE, not 1 or 2.

Example 13-8: We have 1 chunk with 11 processes and 3 VEs, and we want 4 VE processes to run on the first and second VEs, and 3 processes on the third VE:

```
-l select=ncpus=2:nves=3:mpiprocs=11 -v NEC_PROCESS_DIST=4
```

13.4.3.3 Placing Processes on VHs

For each chunk in a job, you can place one or more of the processes on the VH by specifying the number of VH processes. Use the letter "S" before the number of VH processes. You can combine this with the methods for launching processes on VEs (direct launch or VE offloading).

Syntax for distribution of processes on VH:

*NEC_PROCESS_DIST=**S**<VH process count>*

Syntax for distribution of processes for a single chunk on VH and on VEs (the specification for VH process count can appear in any position in the chunk distribution; we show it here in the first position):

*NEC_PROCESS_DIST=**S**<VH process count>:<process count for first VE>[:<process count for second VE> :...: <process count for nth VE>]*

Separate chunks with a plus sign:

*NEC_PROCESS_DIST=**S**<VH process count>:<process count for first VE>[:<process count for second VE> :...: <process count for nth VE>]+**S**<VH process count>:<process count for first VE>[:<process count for second VE> :...: <process count for nth VE>]*

Example 13-9: We have 5 processes and 1 VE. The first 2 processes will run on the VH, and the last 3 will run on the VE:

```
qsub -lselect=1:ncpus=2:nves=1:mpiprocs=5 -v NEC_PROCESS_DIST=S2:3
```

13.4.3.3.i Restrictions and Caveats for Placing Processes on VHs

- When you specify process placement on a VH, you must request the ncpus resource to reserve CPUs for those processes.
- You can specify VH process distribution only once per chunk.
- If you specify VH processes, you must specify at least one VH process; you cannot specify zero VH processes.

13.4.3.4 Using VE Offloading

In offloading, NEC MPI launches main processes on the vector host, and those processes then launch (offload) parallel and/or vectorized numeric operations on vector engines that are attached to the vector host and assigned to the job. A process that has been offloaded to a VE is not directly started by NEC MPI.

A VE process that has not been offloaded is directly started by NEC MPI on the VE.

VE offloading is applied chunk by chunk; you specify which chunks should use it. In any chunk, you can either use VE offloading or not; you cannot mix offloading and direct launch on VEs by NEC MPI in the same chunk.

To offload processes to VEs:

- Use the nves resource to specify the number of VEs you need for offloading
- Use the NEC_PROCESS_DIST environment variable to specify that one or more processes should start on the VH
- Specify that no processes should be started directly by NEC MPI on VEs
- Make sure that the number of processes in the `mpirun` command and the total number of mpiprocs is the same, because NEC MPI launches only the processes on the VH; it does not launch processes that are offloaded.

We use a specific syntax to indicate offloading, regardless of the number of VEs. While it may seem that logically equivalent syntax should also work, it will not. Specify zero for the first VE only, and nothing else for other VEs. Syntax for VE offloading:

NEC_PROCESS_DIST=S<number of VH processes>:0

Example 13-10: We will run 2 processes on the VH, and offload 3 processes to the VEs. Process `vh.out` launches `ve.out` on attached VEs:

```
qsub -l select=ncpus=2:mpiprocs=2:nves=2 -v NEC_PROCESS_DIST=S2:0
```

In job script:

```
mpirun -vh -np 2 vh.out
```

13.4.3.4.i Restrictions and Caveats for VE Offloading

The syntax for VE offloading is ***S<VH process count>:0***, not S<VH process count>:0:0:0 or S<VH process count>, despite the fact that the last two look logically equivalent.

13.4.3.5 Replicating the Same Process Distribution Across Multiple Chunks

If you have a group of identical chunks, you can specify the process placement for the first of these chunks, and PBS can replicate the placement for the remaining identical chunks. (You can repeat the specification for each identical chunk if you want, but you don't need to.) Syntax for process distribution for one group of identical chunks:

NEC_PROCESS_DIST = <distribution for all chunks in group>

Example 13-11: We have 2 identical chunks, each with 6 processes and 3 VEs, and for each chunk we want 1 process to run on the first VE, 3 on the second, and 2 on the third. We specify the distribution for the first chunk, and PBS replicates it for the remaining identical chunk:

```
qsub -lselect=2:ncpus=2:nves=3:mpiprocs=6 -v NEC_PROCESS_DIST=1:3:2
```

If you have more than one group of identical chunks, where each group is different, you can specify just the first chunk for each group. Syntax for process distribution for multiple groups of identical chunks:

NEC_PROCESS_DIST = <group1 chunk distribution>+<group2 chunk distribution> +... + <group N chunk distribution>

Example 13-12: We have 2 groups of chunks:

The first group is 2 chunks that have 6 processes and 3 VEs and we want 1 process to run on the first VE, 3 on the second, and 2 on the third.

For the second group of 2 chunks, we have 6 processes evenly distributed across 2 VEs.

We specify the distribution for the first chunk in each group, and PBS replicates it for the remaining identical chunk in each group:

```
qsub -lselect=2:ncpus=2:nves=3:mpiprocs=6+2:nves=2:mpiprocs=6 -v NEC_PROCESS_DIST=1:3:2+3
```

13.4.3.6 Examples of Specifying Process Distribution

In the following examples, we'll use `vh.out` as the name of a process that runs on VHs, and `ve.out` as the name of the process that runs on VEs.

Example 13-13: We have 6 processes, and 3 VEs, and we want 1 process to run on the first VE, 3 on the second, and 2 on the third:

```
qsub -lselect=1:ncpus=2:nves=3:mpiprocs=6 -v NEC_PROCESS_DIST=1:3:2
```

In job script:

```
mpirun -np 6 ve.out
```

Example 13-14: We have 1 chunk with 6 processes and 2 VEs, and we want 3 VE processes to run on each VE:

```
qsub -l select=ncpus=2:nves=2:mpiprocs=6 -v NEC_PROCESS_DIST=3
```

In job script:

```
mpirun -np 6 ve.out
```

Example 13-15: We have 2 chunks:

In the first chunk, we have 6 processes, and 3 VEs, and we want 1 process to run on the first VE, 3 on the second, and 2 on the third.

In the second chunk, we have 6 processes and 2 VEs, and we want 3 VE processes to run on each VE (combining examples 13-13 and 13-14):

```
qsub -lselect=1:ncpus=2:nves=3:mpiprocs=6+1:ncpus=2:nves=2:mpiprocs=6 -v NEC_PROCESS_DIST=1:3:2+3
```

In job script:

```
mpirun -np 12 ve.out
```

Example 13-16: We have 3 chunks:

In the first chunk, we have 5 processes and 1 VE. The first 2 processes will run on the VH, and the last 3 will run on the VE.

In the second chunk, we have 6 processes and 3 VEs; 1 process will run on the VH and 5 will run on the VEs.

In the third chunk, we'll run 4 processes on a VE:

```
qsub -l
    select=1:ncpus=2:nves=1:mpiprocs=5+1:ncpus=2:nves=3:mpiprocs=6+1:ncpus=2:nves=1:mpiprocs=4 -v
    NEC_PROCESS_DIST=S2:3+2:1:S1:2+4
```

In job script:

```
mpirun -vh -np 2 vh.out : -np 6 ve.out : -vh -np 1 vh.out : -np 6 ve.out
```

Example 13-17: We have 2 chunks:

In the first chunk, process `vh.out` launches 3 processes `ve.out` on attached VEs.

In the second chunk, we run 4 processes on 2 VEs:

```
qsub -l select=ncpus=2:mpiprocs=2:nves=2+1:ncpus=2:nves=2:mpiprocs=4 -v NEC_PROCESS_DIST=S2:0+2
```

In job script:

```
mpirun -vh -np 2 vh.out : -np 4 ve.out
```

Example 13-18: We have 3 groups of chunks:

The first group is 2 chunks that have 6 processes and 3 VEs and we want 1 process to run on the first VE, 3 on the second, and 2 on the third.

For the second group of 2 chunks, we have 6 processes evenly distributed across 2 VEs.

For the third group, we have 3 chunks, and we run 1 process on the VH and 2 processes on a VE.

We specify the distribution for the first chunk in each group, and PBS replicates it for the remaining identical chunk in each group:

```
qsub -lselect=2:ncpus=2:nves=3:mpiprocs=6+2:nves=2:mpiprocs=6+3:ncpus=2:nves=1:mpiprocs=3  -v
    NEC_PROCESS_DIST=1:3:2+3+S1:2
```

In the job script:

```
mpirun -np 24 ve.out : -vh -np 1 vh.out : -np 2 ve.out : -vh -np 1 vh.out : -np 2 ve.out : -vh -np
    1 vh.out : -np 2 ve.out
```

Example 13-19: We have 3 chunks:

In the first chunk, we have 5 processes and 1 VE. The first 2 processes will run on the VH, and the last 3 will run on the VE.

In the second chunk, we have 3 processes, all of which will run on the VH.

In the third chunk, we'll run 4 processes on a VE:

```
qsub -l select=1:ncpus=2:nves=1:mpiprocs=5+1:ncpus=3:mpiprocs=3+1:ncpus=2:nves=1:mpiprocs=4 -v
    NEC_PROCESS_DIST=S2:3+S3+4
```

In job script:

```
mpirun -vh -np 2 vh.out : -np 3 ve.out : -vh -np 3 vh.out : -np 4 ve.out
```

13.4.3.7 Restrictions and Caveats for Specifying Process Distribution

- If you use the NEC_PROCESS_DIST environment variable for a job, you must request the mpiprocs resource for all chunks in the job.
- For each job, make sure that the number of chunks in your select specification is the same as the number in NEC_PROCESS_DIST.
- For each chunk, the sum of the specified VE processes and VH processes must be equal to the sum of mpiprocs. You can imply even distribution, as in section 13.4.3.2.i, “Implying Perfect Distribution”, on page 209.
- If you specify distribution for any VEs in a job, you must specify distribution for all VEs in all chunks of the job. You can imply even distribution, as in section 13.4.3.2.i, “Implying Perfect Distribution”, on page 209.
- When you are not using VE offloading, you cannot specify a count of zero processes on any VEs.

13.5 Job Accounting on NEC SX-Aurora TSUBASA

When PBS writes accounting records, PBS records nves in both Resource_List.nves and resources_assigned.nves. PBS also writes ve_mem and ve_cput as part of the value of the job's resources_used attribute.

13.6 Environment Variables for NEC MPI

Before launching a job requesting vector engines, PBS sets the following environment variables on each execution host:

_VENODELIST

List of VE numbers assigned to this job on a VH.

For example, PBS assigns VE numbers 0-3 to a job on a VH via `export _VENODELIST="0 1 2 3";` if no VEs are assigned to a job on a VH, you get `export _VENODELIST=""`

VE_NODE_NUMBER

The lowest VE number assigned to this job on a VH.

For example, PBS assigns VE numbers 0-3 on a VH via `export VE_NODE_NUMBER="0";` if no VEs are assigned to a job on a VH, you get `export VE_NODE_NUMBER=-1`

_NECMPI_VE_NUM_NODES

Number of vector engines assigned to this job which are directly used by NEC MPI and not used for VE off-loading.

For example, PBS assigns VE numbers 0-3 to a job on a VH via `export _NECMPI_VE_NUM_NODES=4`

_NECMPI_VE_NODELIST

Space-separated list of VE numbers assigned to this job which are directly used by NEC MPI and not used for VE offloading.

For example, PBS assigns VE numbers 0-3 to a job on a VH via `export _NECMPI_VE_NODELIST="0 1 2 3"`

_NEC_HCA_LIST_IO

Space-separated list of HCA-lists assigned to this job on this vector host.

An HCA-list is a comma-separated list of HCAs assigned to this job on each VE.

When a job requests nhcas for a job chunk, PBS sets _NEC_HCA_LIST_IO accordingly for that chunk. When nhcas is not requested for a chunk, PBS sets _NEC_HCA_LIST_IO to include all HCAs on a host.

For example, if there are two VEs and two HCAs (labeled mlx5_0:1 and mlx5_1:1) attached to the VH, and each VE uses both HCAs, _NEC_HCA_LIST_IO=mlx5_0:1,mlx5_1:1 mlx5_0:1,mlx5_1:1

_NEC_HCA_LIST_MPI

Space-separated list of HCA-lists for each VE used by this job, and not used for offloading. See the environment variable _NEC_HCA_LIST_IO

When a job requests nhcas for a job chunk, PBS sets _NEC_HCA_LIST_MPI accordingly for that chunk. When nhcas is not requested for a chunk, PBS sets _NEC_HCA_LIST_MPI to include all HCAs on a host.

For example, if there are two VEs and two HCAs (labeled mlx5_0:1 and mlx5_1:1) attached to the VH, and each VE uses both HCAs, but one of the VEs is used for offloading,
_NEC_HCA_LIST_IO=mlx5_0:1,mlx5_1:1

14 Using MLS with PBS Professional

14.1 About SELinux PBS Professional

With this version of PBS Professional, we offer a separate software package that supports SELinux enforcement mode used with one or more MLS policies on RHEL 7. In this chapter, we describe how to use SELinux PBS only.

14.2 Requirement for Submitting Jobs

When you submit a job to PBS, you must do so from a machine running this version of the PBS commands. This version of PBS includes the security_context job attribute, and if it is missing, an error occurs, a server message is logged, and the job is rejected.

14.3 Viewing and Operating on Jobs

When a user queries or operates on his or her own job, PBS requires that the security_context attribute of the job match the security context of the requester. It is not sufficient that the credential of the requester dominate that of the job.

14.3.1 Checking Security Context

PBS writes the security context for a job in its security_context attribute. For example, if you need to compare the security context of jobs and users:

Find job security context:

```
bash-4.2$ qstat -f | grep security
security_context = user_u:user_r:user_t:s3:c1,c2
```

Find user security context:

```
bash-4.2$ id -Z
user_u:user_r:user_t:s3:c1,c2
```

14.4 Credentials of Deleted Jobs

When a job is deleted via `qdel` or `qdel -x`, the job's credentials are handled the same way they would be if PBS were not being used.

14.5 Caveats

If your site is using polyinstantiation and MoM (the execution service process) dies or is told to exit while there are running jobs, you may need to manually clean up directories and/or files created for those jobs after the jobs have exited.

14.6 Errors and Logging

14.6.1 Logging

PBS may log the following messages in the server and/or MoM logs:

Table 14-1: Log Messages

Message	Log Level
no security context found	Error (0x0001)
failed to read credential file	Error (0x0001)
job credential <context>	Debug (0x0080)
unable to create the job directory	Error (0x0001)
the staging and execution directory <dir> already exists	Debug3 (0x0400)
could not set security context for <dir>	Error (0x0001)
unable to change permissions on staging and execution directory <dir>	Debug (0x0080)
unable to open user session	Debug4 (0x0800)
unable to start job, no security context found or not able to set security context	Error (0x0001)
cannot get current socket context	Error (0x0001)
cannot set socket context for <jobid>	Error (0x0001)
cannot restore socket context	Error (0x0001)
failed to set file context for <dir>	Error (0x0001)
could not save security context	Debug (0x0080)
saved security context	Debug (0x0080)
client connection no security context information present	Security (0x0020)
client connection security context information present, but no job security context information present	Security (0x0020)
client connection security context information not present, but job security context information present	Security (0x0020)
client connection security context information job security context information do not match	Security (0x0020)

14.6.2 Errors

PBS may write the following error messages to the job submitter's standard error:

```
"pbs_iff:  fgetfilecon(1) returned -1"
"pbs_iff:  filecon overflow"
"pbs_iff:  malloc extendarg failed"
```

15 Using Provisioning

PBS provides automatic provisioning of an OS or application on vnodes that are configured to be provisioned. When a job requires an OS that is available but not running, or an application that is not installed, PBS provisions the vnode with that OS or application.

15.1 Definitions

AOE

The environment on a vnode. This may be one that results from provisioning that vnode, or one that is already in place

Provision

To install an OS or application, or to run a script which performs installation and/or setup

Provisioned Vnode

A vnode which, through the process of provisioning, has an OS or application that was installed, or which has had a script run on it

15.2 How Provisioning Works

Provisioning can be performed only on vnodes that have provisioning enabled, shown in the vnode's provision_enable attribute.

Provisioning can be the following:

- Directly installing an OS or application
- Running a script which may perform setup or installation

Each vnode is individually configured for provisioning with a list of available AOEs, in the vnode's resources_available.aoe attribute.

Each vnode's current_aoe attribute shows that vnode's current AOE. The scheduler queries each vnode's aoe resource and current_aoe attribute in order to determine which vnodes to provision for each job.

Provisioning can be used for interactive jobs.

A job's walltime clock starts when provisioning for the job has finished.

15.2.1 Causing Vnodes To Be Provisioned

An AOE can be requested for a job or a reservation. When a job requests an AOE, that means that the job will be run on vnodes running that AOE. When a reservation requests an AOE, that means that the reservation reserves vnodes that have that AOE available. The AOE is instantiated on reserved vnodes only when a job requesting that AOE runs.

When the scheduler runs each job that requests an AOE, it either finds the vnodes that satisfy the job's requirements, or provisions the required vnodes. For example, if SLES is available on a set of vnodes that otherwise suit your job, you can request SLES for your job, and regardless of the OS running on those vnodes before your job starts, SLES will be running at the time the job begins execution.

15.2.2 Using an AOE

When you request an AOE for a job, the requested AOE must be one of the AOEs that has been configured at your site. For example, if the AOEs available on vnodes are "*rhel*" and "*sles*", you can request only those; you cannot request "*suse*".

Your job can run where its requested AOE can be supplied both by provisioning and where the AOE already matches the request. Some of your job chunks can run on the non-provisionable vnodes that already match the requested AOE, and some chunks can run on vnodes that can be provisioned to match the requested AOE.

You can request a reservation for vnodes that have a specific AOE available. This way, jobs needing that AOE can be submitted to that reservation. This means that jobs needing that AOE are guaranteed to be running on vnodes that have that AOE available.

Each reservation can have at most one AOE specified for it. Any jobs that run in that reservation must not request a different AOE from the one requested for the reservation. That is, the job can run in the reservation if it either requests no AOE, or requests the same AOE as the reservation.

15.2.3 Job Substates and Provisioning

When a job is in the process of provisioning, its substate is *provisioning*. This is the description of the substate:

provisioning

The job is waiting for vnode(s) to be provisioned with its requested AOE. Integer value is *71*. See "Job Substates" on page 361 of the PBS Professional Reference Guide for a list of job substates.

The following table shows how provisioning events affect job states and substates:

Table 15-1: Provisioning Events and Job States/Substates

Event	Initial Job State, Substate	Resulting Job State, Substate
Job submitted		*Queued and ready for selection*
Provisioning starts	*Queued, Queued*	*Running, Provisioning*
Provisioning fails to start	*Queued, Queued*	*Held, Held*
Provisioning fails	*Running, Provisioning*	*Queued, Queued*
Provisioning succeeds and job runs	*Running, Provisioning*	*Running, Running*
Internal error occurs	*Running, Provisioning*	*Held, Held*

15.3 Requirements and Restrictions

15.3.1 Host Restrictions

15.3.1.1 Single-vnode Hosts Only

PBS will provision only single-vnode hosts. Do not attempt to use provisioning on hosts that have more than one vnode.

15.3.1.2 Server Host Cannot Be Provisioned

The server host cannot be provisioned: a MoM can run on the server host, but that MoM's vnode cannot be provisioned. The provision_enable vnode attribute, resources_available.aoe, and current_aoe cannot be set on the server host.

15.3.2 AOE Restrictions

Only one AOE can be instantiated at a time on a vnode.

Only one kind of aoe resource can be requested in a job. For example, an acceptable job could make the following request:

```
-l select=1:ncpus=1:aoe=suse+1:ncpus=2:aoe=suse
```

15.3.2.1 Vnode Job Restrictions

A vnode with any of the following jobs will not be selected for provisioning:

- One or more running jobs
- A suspended job
- A job being backfilled around

15.3.2.2 Provisioning Job Restrictions

A job that requests an AOE will not be backfilled around.

15.3.2.3 Vnode Reservation Restrictions

A vnode will not be selected for provisioning for job MyJob if the vnode has a confirmed reservation, and the start time of the reservation is before job MyJob will end.

A vnode will not be selected for provisioning for a job in reservation R1 if the vnode has a confirmed reservation R2, and an occurrence of R1 and an occurrence of R2 overlap in time and share a vnode for which different AOEs are requested by the two occurrences.

15.3.3 Requirements for Jobs

15.3.3.1 If AOE is Requested, All Chunks Must Use Same AOE

If any chunk of a job requests an AOE, all chunks must use that AOE, even if they do not explicitly request an AOE. For example, if your job requests

```
-l select=2:ncpus=1:aoe=suse+4:ncpus=2
```

all chunks must use the *suse* AOE.

If a job requesting an AOE is submitted to a reservation, that reservation must also request the same AOE.

15.4 Using Provisioning

15.4.1 Requesting Provisioning

You request a reservation with an AOE in order to reserve the resources and AOE required to run a job. You request an AOE for a job if that job requires that AOE. You request provisioning for a job or reservation using the same syntax.

You can request an AOE for the entire job/reservation:

-l aoe = <AOE>

Example:

```
-l aoe = suse
```

The *-l <AOE>* form cannot be used with *-l select.*

You can request an AOE for a single-chunk job/reservation:

-l select=<chunk request>:aoe=<AOE>

Example:

```
-ls select=1:ncpus=2:aoe=rhel
```

You can request the same AOE for each chunk of a job/reservation:

-l select=<chunk request>:aoe=<AOE> + <chunk request>:aoe=<AOE>

Example:

```
-l select=1:ncpus=1:aoe=suse + 2:ncpus=2:aoe=suse
```

You can request the an AOE for some, but not all, chunks of a job/reservation:

-l select=<chunk request>:aoe=<AOE> + <chunk request>

Example:

```
-l select=1:ncpus=1:aoe=suse + 2:ncpus=2
```

15.4.2 Commands and Provisioning

If you try to use PBS commands on a job that is in the *provisioning* substate, the commands behave differently. The provisioning of vnodes is not affected by the commands; if provisioning has already started, it will continue. The following table lists the affected commands:

Table 15-2: Effect of Commands on Jobs in Provisioning Substate

Command	Behavior While in Provisioning Substate
`qdel`	(Without force) Job is not deleted
	(With force) Job is deleted
`qsig -s suspend`	Job is not suspended
`qhold`	Job is not held
`qrerun`	Job is not requeued

Table 15-2: Effect of Commands on Jobs in Provisioning Substate

Command	Behavior While in Provisioning Substate
qmove	Cannot be used on a job that is provisioning
qalter	Cannot be used on a job that is provisioning
qrun	Cannot be used on a job that is provisioning

15.4.3 How Provisioning Affects Jobs

A job that has requested an AOE will not preempt another job. Therefore no job will be terminated in order to run a job with a requested AOE.

A job that has requested an AOE will not be backfilled around.

15.5 Caveats and Errors

15.5.1 Requested Job AOE and Reservation AOE Should Match

Do not submit jobs that request an AOE to a reservation that does not request the same AOE. Reserved vnodes may not supply that AOE; your job will not run.

15.5.2 Allow Enough Time in Reservations

If a job is submitted to a reservation with a duration close to the walltime of the job, provisioning could cause the job to be terminated before it finishes running, or to be prevented from starting. If a reservation is designed to take jobs requesting an AOE, leave enough extra time in the reservation for provisioning.

15.5.3 Requesting Multiple AOEs For a Job or Reservation

Do not request more than one AOE per job or reservation. The job will not run, or the reservation will remain unconfirmed.

15.5.4 Held and Requeued Jobs

The job is held with a system hold for the following reasons:

- Provisioning fails due to invalid provisioning request or to internal system error
- After provisioning, the AOE reported by the vnode does not match the AOE requested by the job

The hold can be released by the PBS Administrator after investigating what went wrong and correcting the mistake.

The job is requeued for the following reasons:

- The provisioning hook fails due to timeout
- The vnode is not reported back up

15.5.5 Conflicting Resource Requests

The values of the resources arch and vnode may be changed by provisioning. Do not request an AOE and either arch or vnode for the same job.

15.5.6 Job Submission and Alteration Have Same Requirements

Whether you use the `qsub` command to submit a job, or the `qalter` command to alter a job, the job must eventually meet the same requirements. You cannot submit a job that meets the requirements, then alter it so that it does not.

16 Using Accounting

16.1 Using Accounting

16.1.1 Specifying Accounting String

You can associate an accounting string with your job by setting the value of the Account_Name job attribute. This attribute has no default value. You can set the value of Account_Name at the command line or in a PBS directive:

```
qsub -A <accounting string>
#PBS Account_Name=<accounting string>
```

The <*accounting string*> can be any string of characters; PBS does not attempt to interpret it.

You can use the `qalter` command to change the value of the Account_Name job attribute while the job is queued, but not while the job is running.

16.1.2 Using Comprehensive System Accounting

You can use CSA on Cray systems running CLE 5.2. PBS support for CSA on HPE systems is no longer available. The CSA functionality for HPE systems has been **removed** from PBS.

CSA provides accounting information about user jobs, called user job accounting.

CSA works the same with and without PBS. To run user job accounting, either you must specify the file to which raw accounting information will be written, or an environment variable must be set. The environment variable is ACCT_TMPDIR. This is the directory where a temporary file of raw accounting data is written.

To run user job accounting, you issue the CSA command "`ja <filename>`" or, if the environment variable ACCT_TMPDIR is set, "`ja`". In order to have an accounting report produced, you issue the command "`ja -<options>`" where the options specify that a report should be written and what kind to write. To end user job accounting, you issue the command "`ja -t`"; the `-t` option can be included in the previous set of options. See the man page on `ja` for details.

The starting and ending `ja` commands must be used before and after any other commands you wish to monitor. Here are examples of a command line and a script:

On the command line:

```
qsub -N myjobname -l ncpus=1
    ja myrawfile
    sleep 50
    ja -c > myreport
    ja -t myrawfile
ctrl-D
```

Accounting data for your job (sleep 50) is written to `myreport`.

If you create a job script foo with these commands:

```
#PBS -N myjobname
#PBS -l ncpus=1
ja myrawfile
sleep 50
ja -c > myreport
ja -t myrawfile
```

Then you can run your job script via qsub, to do the same thing as in the previous example:

```
qsub foo
```

16.1.3 Using Dependencies with Accounting

If you need to run end-of-day accounting, you can use dependencies; see section 6.2, “Using Job Dependencies”, on page 109

16.1.4 Advice and Caveats for Using Accounting

16.1.4.1 Use an Integrated MPI

Many MPIs are integrated with PBS. PBS provides tools to integrate most of them; a few MPIs supply the integration. When a job is run under an integrated MPI, PBS can track resource usage, signal job processes, and perform accounting for all processes of the job.

When a job is run under an MPI that is not integrated with PBS, PBS is limited to managing the job only on the primary vnode, so resource tracking, job signaling, and accounting happen only for the processes on the primary vnode.

Under Windows, some MPIs such as MPICH are not integrated with PBS.

See section 5.2.1, “Using an Integrated MPI”, on page 83.

Contents

List of APIs

21 PBS Architecture

PBS is a distributed workload management system which manages and monitors the computational workload on a set of one or more computers.

21.1 PBS Components

You can manage one or more machines using PBS. PBS consists of commands, a data service, and the following daemons:

- Server daemon for central management; this daemon runs on Linux only.
- One or more scheduler daemons to schedule jobs; schedulers run on Linux only.
- Communication daemon to manage communication; this daemon also runs only on Linux.
- Job management daemon called MoM to manage each execution host; this daemon can run on Linux or Windows.

The data service runs on Linux only. Commands can run on Linux or Windows.

21.1.1 Single Execution System

If PBS is to manage a single system, all components are installed on that same system. For installation instructions, see the *PBS Professional Installation & Upgrade Guide*.

The following illustration shows how communication works when PBS is on a single host in TPP mode. For more on TPP mode, see "Communication" on page 45 in the PBS Professional Installation & Upgrade Guide.

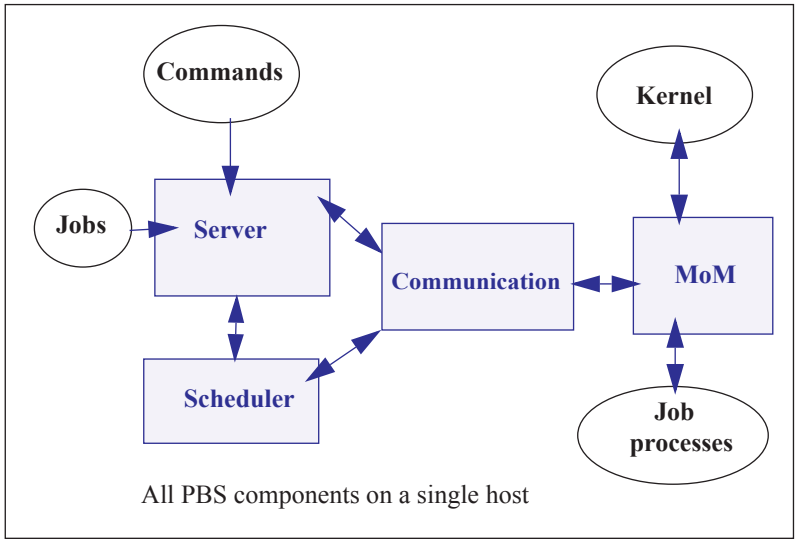

Figure 21-1:PBS daemons on a single execution host

21.1.2 Single Execution System with Front End

The PBS server and default scheduler (`pbs_server` and `pbs_sched`) can run on one system and jobs can execute on another. Job execution is managed by the MoM daemon. The following illustration shows how communication works when the PBS server and scheduler are on a front-end system and MoM is on a separate host, in TPP mode. For more on TPP mode, see "Communication" on page 45 in the PBS Professional Installation & Upgrade Guide.

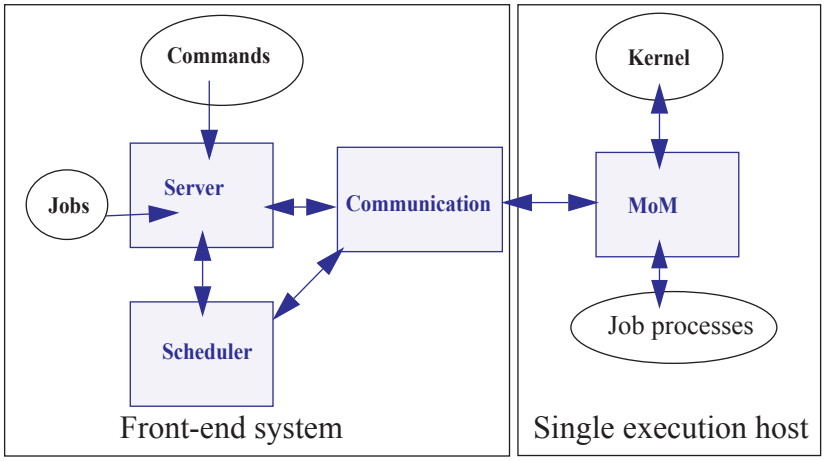

Figure 21-2:PBS daemons on single execution system with front end

21.1.3 Multiple Execution Systems

When you run PBS on several systems, the server (`pbs_server`), the scheduler (`pbs_sched`), and the communication daemon (`pbs_comm`) are installed on a "front end" system, and a MoM (`pbs_mom`) is installed and run on each execution host. The following diagram illustrates this for an eight-host complex in TPP mode.

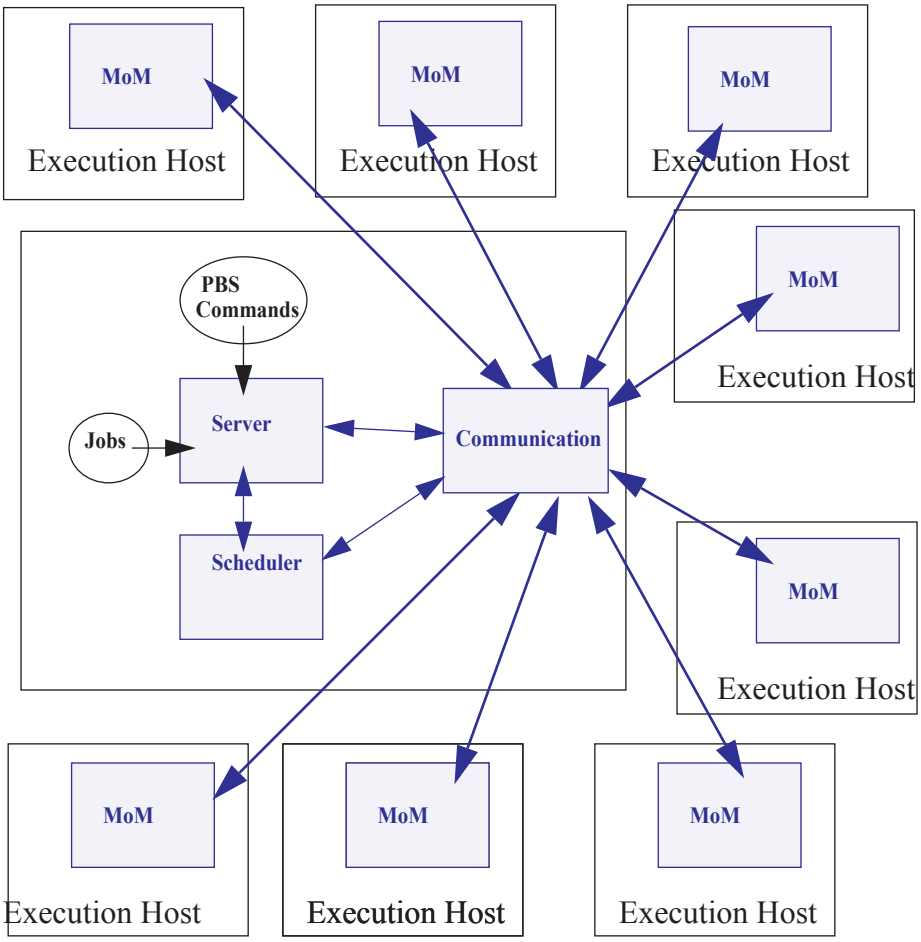

Figure 21-3:Typical PBS daemon locations for multiple execution hosts

21.1.4 Server

The *server* process is the central focus for PBS. In our documentation, it is generally referred to as *the server, the PBS server,* or by the execution name *pbs_server.* All commands and communication with the server are via an *Internet Protocol* (IP) network. The server provides core batch services such as receiving batch job requests, creating batch jobs, modifying jobs, protecting jobs against system crashes, and sending jobs to MoM for execution. One server manages each PBS complex.

21.1.5 Job Executor (MoM)

The *Job Executor* is the component that actually places the job into execution. This daemon, *pbs_mom,* is informally called *MoM* as it is the mother of all executing jobs on that host. MoM places a job into execution when it receives a copy of the job from the server. MoM creates a new session that is as identical to a user login session as is possible. For example, if the user's login shell is `csh`, then MoM creates a session in which `.login` is run as well as `.cshrc`. MoM also returns the job's output to the user. One MoM runs on each execution host (a host where PBS jobs execute).

21.1.6 Schedulers

PBS has a default scheduler; if you want to schedule individual partitions separately, you can add any number of additional schedulers, called *multischeds*. Each PBS scheduler follows its own scheduling policy.

Each scheduler daemon implements a policy that you define that controls when each job is run and on which resources. See "About Schedulers" on page 91 in the PBS Professional Administrator's Guide.

Each scheduler makes a persistent connection to the server via `pbs_connect()`. If the scheduler does not have a connection to the server, it continues trying every 2 seconds until it gets a connection.

21.1.7 Communication Daemon

The *communication daemon*, `pbs_comm`, handles communication between the other PBS daemons. For a complete description, see section 4.5, "Inter-daemon Communication Using TPP", on page 49.

21.1.8 Privilege

PBS recognizes separate roles and levels of privilege: Manager role is required for sensitive operations, Operator role can perform various less-sensitive functions, and User role allows access to only the user's own jobs. Root privilege is required for some of the Manager operations; the combination of root privilege and Manager role is called PBS Administrator. See "Security" on page 489 in the PBS Professional Administrator's Guide.

21.1.9 Commands

PBS provides a set of commands for submitting and managing jobs, and for managing PBS. PBS commands are described in "PBS Commands" on page 21 of the PBS Professional Reference Guide.

22 Server Functions

22.1 Roles and Required Privilege

PBS recognizes specific roles and levels of privilege, and these are required for some operations on PBS. For details, see "User Roles and Required Privilege" on page 489 in the PBS Professional Administrator's Guide.

22.2 Batch Server Functions

A batch server provides services in the following ways:

- The server provides a service at the request of a client. Clients are processes that make requests of a batch server. The requests may ask for an action to be performed on one or more jobs, one or more queues, the server itself, etc. Any requests that cannot be successfully completed are rejected. The reason for the rejection is returned in the reply to the client.
- The server provides a deferred service when it detects a change in conditions that it monitors. The server may, depending on conditions being monitored, defer a client service request until a later time. Deferred services include file staging, sending jobs for execution, etc. See section 22.8, "Deferred Services", on page 12.

The server also performs a number of internal bookkeeping functions.

22.3 Server Management

The following sections describe the services provided by a batch server in response to a request from a client. The requests are grouped in the following subsections by the type of object affected by the request: server, queue, job, reservation, vnode, hook, or resource. The batch requests described in this section control the functioning of the batch server. The control is either direct as in the *Shut Down* request, or indirect as when server attributes are modified. For a list of batch request codes, see "Request Codes" on page 393 of the PBS Professional Reference Guide.

22.3.1 Manage Request

The *Manage* request supports `qmgr` and other commands. For more information, see "qmgr" on page 152 of the PBS Professional Reference Guide.

22.3.2 Server Status Request

The status of the server may be requested with a server *Status* request. The batch server will reject the request if the user of the client is not authorized to query the status of the server. If the request is accepted, the server will return a server *Status Reply*. See "qstat" on page 200 of the PBS Professional Reference Guide details of which server attributes are returned to the client.

22.3.3 Starting the PBS Server

A batch request to start a server cannot be sent to a server since the server is not running. Therefore a batch server must be started by a process local to the host on which the server is to run. For how to start the server, see "Server: Starting, Stopping, Restarting" on page 145 in the PBS Professional Installation & Upgrade Guide.

The server recovers the state of managed objects, such as queues and jobs, from the information last recorded by the server. The.treatment of jobs which were in the running state when the server previously shut down is dictated by the start up mode; see "pbs_server" on page 107 of the PBS Professional Reference Guide.

22.3.4 Stopping the PBS Server

The batch server is "shut down" when it no longer responds to requests from clients and does not perform deferred services. The batch server is requested to shut down by sending it a server *Shutdown* request. The server will reject the request from a client not authorized to shut down the server. When the server accepts a shut down request, it will terminate in the manner described in "qterm" on page 236 of the PBS Professional Reference Guide. When shutting down, the server must record the state of all managed objects (jobs, queues, etc.) in non-volatile memory. Jobs which were running will be marked in the secondary state field for possible special treatment when the server is restarted. If checkpoint is supported, any job running at the time of the shut down request whose Checkpoint attribute is not *n*, will be checkpointed. This includes jobs whose Checkpoint attribute value is "unspecified", a value of *u*. If the server receives either a SIGTERM or a SIGSHUTDN signal, the server will act as if it had received a shut down immediate request.

22.4 Queue Management

The following client requests operate on the queues managed by the server.

22.4.1 Queue Status Request

The status of a queue at the server may be requested with a *Queue Status* request. The batch server requires that the following conditions are true:

- The user of the client is authorized to query the status of the designated queue
- The specified queue exists on the server

If the request does not specify a queue, status of all the queues at the server will be returned. When the request is accepted, the server will return a *Queue Status Reply*. See"qstat" on page 200 of the PBS Professional Reference Guide for details of which queue attributes are returned to the client.

22.5 Vnode Management

22.5.1 Modify Vnode Request

The *ModifyVnode* request tells the server to modify a vnode. Modifications include state changes.

22.6 Job Management

The following client requests operate on jobs managed by the server. These requests do not require any special privilege except when the job for which the request is issued is not owned by the user making the request.

22.6.1 Queue Job Request

A *Queue Job* request consists of several subrequests: Initiate *Job Transfer*, *Job Data*, *Job Script*, and *Commit*. The end result of a successful *Queue Job* request is an additional job being managed by the server. The job may have been created by the request or it may have been moved from another server. After the successful request, the job resides in a queue managed by the server. When a queue is not specified in the request, the job is placed in the default queue. The administrator can specify the default queue. We call the queue where the job ends up the *target queue*. The batch server requires that the following conditions are true:

- The client is authorized to create a job in the target queue
- The target queue exists at the server.
- The target queue is enabled.
- If the target queue is an execution queue, no resource requirement of the job exceeds the limits set for the queue
- If the target queue is an execution queue, all resources requested by the job are recognized
- The job requires access to a user identifier that the client is authorized to access

When a job is placed in an execution queue, it is put in the queued state unless one of the following conditions applies:

- The job has an Execution_Time attribute that specifies a time in the future and the Hold_Types attribute has value of *no hold*, in which case the job is placed in the waiting state
- The job has a Hold_Types attribute with a value other than *no hold*, in which case the job is placed in the held state.

When a job is placed in a routing queue, its state may change based on the conditions described in section 22.8.4, “Job Routing”, on page 16.

A server that accepts a *Queue Job* request for a new job will do the following:

- Add the PBS_O_QUEUE variable to the Variable_List attribute of the job and set the value to the name of the target queue
- Add the PBS_JOBID variable to the Variable_List attribute of the job and set the value to the job identifier assigned to the job
- Add the PBS_JOBNAME variable to the Variable_List attribute of the job and set the value to the value of the Job_Name attribute of the job

When the server accepts a *Queue Job* request for an existing job, the server will send a *Track Job* request to the server which created the job.

22.6.2 Job Credential Request

The *Job Credential* sub-request is part of the *Queue Job* request. This sub-request transfers a copy of the credential provided by the authentication facility explained below.

22.6.3 Job Script Request

The *Job Script* sub-request is part of the *Queue Job* request. This sub-request passes a block of the job script file to the receiving server. The script is broken into blocks to prevent having to hold the entire script in memory. Multiple *Job Script* sub-requests may be required to transfer the script file.

22.6.4 Commit Request

The *Commit* sub-request is part of the *Queue Job* request. The *Commit* notifies the receiving server that all parts of the job have been transferred and the receiving server should now assume ownership of the job. Prior to sending the *Commit*, the sending client, command, or another server, is the owner.

22.6.5 Message Job Request

A batch server can be requested to write a string of characters to one or both output streams of an executing job. This request is primarily used by an operator to record a message for the user. The batch server will accept a *Message Job* request if all of the following conditions are true:

- The specified job is in the running state
- The user of the client is authorized to post a message to the designated job
- The specified job is owned by the server

When the server accepts the *Message Job* request, it will forward the request to the primary MoM for the job. Upon receiving the *Message Job* request from the server, the MoM will append the message string, followed by a newline character, to the file or files indicated. If no file is indicated, the message will be written to the standard error of the job.

22.6.6 Locate Job Request

A client may ask a server to return the location of a job that was created by or is owned by the server. When the server accepts the *Locate Job* request, it returns a *Locate Reply*. The request will be accepted if all of the following conditions are true:

- The server owns (manages) the job
- The server created the job
- The server is maintaining a record of the current location of the job

22.6.7 Delete Job Request

A *Delete Job* request asks a server to remove a job from the queue in which it exists and not place it elsewhere. The batch server will accept a *Delete Job* request if all of the following conditions are true:

- The user of the client is authorized to delete the designated job.
- The designated job is owned by the server.
- The designated job is in an eligible state. Eligible states are *queued*, *held*, *waiting*, *running*, and *transiting*.

If the job is in the running state, the server will forward the *Delete Job* request to the primary MoM responsible for the job. The MoM daemon will first send a SIGTERM signal to the job process group. After a delay specified by the delete request, or if not specified, the kill_delay queue attribute, the MoM will send a SIGKILL signal to the job process group. The job is then placed into the *exiting* state. Option arguments exist to specify the delay in seconds between the SIGTERM and SIGKILL signals, as well as to force the deletion of the job even if the node it is running on is not responding.

22.6.8 Modify Job Request

A batch client makes a *Modify Job* request to the server to alter the attributes of a job. The batch server will accept a *Modify Job* request if all of the following conditions are true:

- The user of the client is authorized to make the requested modification to the job.
- The designated job is owned by the server.
- The requested modification is consistent with the state of the job.
- A requested resource change would not exceed the limits of the queue or server.
- An recognized resource is requested for a job in an execution queue.

When the batch server accepts a *Modify Job* request, it will modify all the specified attributes of the job. When the batch server rejects a *Modify Job* request, it will modify none of the attributes of the job.

22.6.9 Run Job Request

The *Run Job* request directs the server to place the specified job into immediate execution. The request is issued by a `qrun` command or by the PBS job scheduler.

22.6.10 Rerun Job Request

To rerun a job is to kill the members of the session (process) group of the job and leave the job in the execution queue. If the Hold_Types attribute is not *NONE* , the job is eligible to be re-scheduled for execution. The server will accept the *Rerun Job* request if all of the following conditions are true:

- The user of the client is authorized to rerun the designated job
- The Rerunable attribute of the job is set to *True*
- The job is in the running state
- The server owns the job

When the server accepts the *Rerun Job* request, the request will be forwarded to the primary MoM responsible for the job, who will then perform the following actions:

1. Send a SIGKILL signal to the session (process) group of the job
2. Send an OBIT notice to the server with resource usage information
3. The server will then requeue the job in the execution queue in which it was executing

If the Hold_Types attribute is not *NONE*, the job will be placed in the *held* state. If the execution_time attribute is a future time, the job will be placed in the *waiting* state. Otherwise, the job is.placed in the *queued* state.

22.6.11 Hold Job Request

A client can request that one or more holds be applied to a job. The batch server will accept a *Hold Job* request if all of the following conditions are true:

- The user of the client is authorized to add any of the specified holds
- The batch server manages the specified job

When the server accepts the *Hold Job* request, it will add each specified hold which is not already present to the value of the Hold_Types attribute of the job. If the job is in the *queued* or *waiting* state, it is placed in the *held* state.

If the job is in *running* state:

If checkpoint / restart is supported by the host system, placing a hold on a running job will cause:

a. The job is checkpointed

b. The resources assigned to the job will be released

c. The job is placed in the held state in the execution queue.

If checkpoint / restart is not supported, the server will only set the requested hold type(s). This will have no effect unless the job is rerun or restarted.

22.6.12 Release Job Request

A client can request that one or more holds be removed from a job. A batch server accepts a *Release Job* request if all of the following conditions are true:

- The user of the client is authorized to add (remove) any of the specified holds.
- The batch server manages the specified job.

When the server accepts the *Release Job* request, it will remove each specified type of hold from the value of the Hold_Types attribute of the job. Normally, the job will then be placed in the queued state, unless another hold type is remaining on the job. However, if all holds have been removed, but the Execution_Time attribute specifies a time in the future, the job is placed in the *waiting* state.

22.6.13 Move Job Request

A client can request a server to move a job to a new destination. The batch server will accept a *Move Job* request if all of the following conditions are true:

- The user of the client is authorized to remove the designated job from the queue in which the job resides
- The user of the client is authorized to submit a job to the new destination
- The designated job is owned by the server
- The designated job is in the *queued*, *held*, or *waiting* state
- The new destination is enabled
- The new destination is accessible. When the server accepts a *Move Job* request, it will
  - Queue the designated job at the new destination.
  - Remove the job from the current queue.

If the destination exists at a different server, the current server will transfer the job to the new server by sending a *Queue Job* request sequence to the target server. The server will ensure that a job is neither lost nor duplicated.

22.6.14 Select Jobs Request

A client is able to request from the server a list of jobs owned by that server that match a list of selection criteria. The request is a *Select Jobs* request. All the jobs owned by the server and which the user is authorized to query are initially eligible for selection. Job attribute and resource relationships listed in the request restrict the selection of jobs. Only jobs which have attributes and resources that meet the specified criteria will be selected. The server will reject the request if the queue portion of a specified destination does not exist on the server. When the request is accepted, the server will return a *Select Reply* containing a list of zero or more jobs that met the selection criteria.

22.6.15 Signal Job Request

A batch client is able to request that the server signal the session (process) group of a job. Such a request is called a *Signal Job* request. The batch server will accept a *Signal Job* request if all of the following conditions are true:

- The user of the client is authorized to signal the job
- The job is in the *running* state, except for the special signal "resume" when the job must be in the *Suspended* state
- The server owns the designated job
- The requested signal is supported by the host operating system. (The kill system call returns [EINVAL].)

When the server accepts a request to signal a job, it will forward the request to the primary MoM daemon responsible for the job, who will then send the signal requested by the client to the all processes in the job's session.

22.6.16 Status Job Request

The status of a job or set of jobs at a destination may be requested with a *Status Job* request. The batch server will accept a *Status Job* request if all of the following conditions are true:

- The user of the client is authorized to query the status of the designated job
- The designated job is owned by the server

When the server accepts the request, it will return a *Job Status* message to the client. See the `qstat` command for details of which job attributes are returned to the client. If the request specifies a job identifier, status will be returned only for that job. If the request specifies a destination identifier, status will be returned for all jobs residing within the specified queue that the user is authorized to query.

22.7 Server to Server Requests

Server to server requests are a special category of client requests. They are only issued to a server by another server.

22.7.1 Track Job Request

A client that wishes to request an action be performed on a job must send a batch request to the server that currently manages the job.

As jobs are routed or moved through the batch network, finding the location of the job can be difficult without a tracking service. The Track Job request forms the basis for this service.

A server that queues a job sends a track job request to the server which created the job.

Additional backup location servers may be defined.

A server that receives a track job request records the information contained therein.

This information is made available in response to a Locate Job request.

22.7.2 Job Dependency

PBS supports job dependencies. A job, the "child", can be declared to be dependent on one or more jobs, the "parents". A parent may have any number of children. The dependency is specified as an attribute via the `qsub` command with the `-W depend=<dependency list>` option.

See "qsub" on page 216 of the PBS Professional Reference Guide for the complete specification of the dependency list, and "Using Job Dependencies", on page 109 of the PBS Professional User's Guide for how to use them.

When a server queues a job with a dependency type of *after*, *afterok*, *afternotok*, or *afterany* in an execution queue, the server will send a *Register Dependent Job* request to the server managing the job specified by the associated job identifier. The request will specify that the server is to register the dependency. This actually creates a corresponding *before* type dependency attribute entry on the parent (e.g. run job X *before* job Y). If the request is rejected because the parent job does not exist, the child job is aborted. If the request is accepted, a *system* hold is placed on the child job. When a parent job with any of the *before...* types of dependency reaches the required state, starts, or terminates, the server executing the parent job sends a *Register Dependent Job* request to the server managing the child job directing it to release the child job. If there are no other dependencies on other jobs, the system hold on the child job is removed. When a child job is submitted with an *on* dependency and the parent is submitted with any of the *before...* types of dependencies, the parent will register with the child. This causes the *on* dependency count to be reduced and a corre-

sponding *after...* dependency to be created for the child job. The result is a pairing between corresponding *before...* and *after...* dependency types. If the parent job terminates so that the child is not released, it is up to the user to correct the situation by either deleting the child job or by correcting the problem with the parent job and resubmitting it. If the parent job is resubmitted, it must have a dependency type of *before*, *beforeok*, *beforenotok*, or *beforeany* specified to connect it to the waiting child job.

22.8 Deferred Services

The PBS server uses an internal mechanism of deferred services to handle some work asynchronously.

Servers use deferred services for these job-related tasks:

- File staging
- Job selection
- Job initiation
- Job routing
- Job exit
- Job abort
- Rerunning jobs after a server restart

The following rules apply to deferred services used for jobs:

- If the server cannot complete a deferred service for a reason which is permanent, the job is aborted
- If the service cannot be completed at the current time but may be completed later, the service is retried a finite number of times

22.8.1 Job Scheduling

PBS has a default scheduler; if you want to schedule individual partitions separately, you can add any number of additional schedulers, called *multischeds*. Each PBS scheduler follows its own scheduling policy.

Each scheduler daemon implements a policy that you define that controls when each job is run and on which resources. See "About Schedulers" on page 91 in the PBS Professional Administrator's Guide.

22.8.1.1 Connection Between Scheduler and Server

Each scheduler is persistently connected to the server via `pbs_connect()`. If the scheduler does not have a connection to the server, it continues trying every 2 seconds until it succeeds.

Each scheduler registers itself as a client with the server by sending a PBS_BATCH_RegisterSched batch request. The scheduler passes its name to the server along with this batch request. The administrator must set the scheduler hostname in the sched_host scheduler attribute when creating the scheduler object so that the server can verify that the incoming client request is from the specified scheduler host. The server authenticates the scheduler, and marks this authenticated client as a scheduler.

The scheduler uses `pbs_connect()` to make two connections to the server. After each call to `pbs_connect()`, the scheduler sends a PBS_BATCH_RegisterSched batch request along with its name, and waits for an ACK from the server. The scheduler first establishes a primary connection to the server, and uses it for data and IFL calls. The scheduler then establishes a secondary connection to the server, and uses it to get scheduling commands from the server and to send end-of-cycle notifications to the server. After the scheduler receives an ACK for both connections, it waits for scheduling commands from the server. The server waits for each end-of-cycle notification before sending the next scheduling command.

22.8.1.1.i Process for Server to Accept Scheduler Connection Request

1. When the server receives a request to register a scheduler, the server verifies that the connection is authenticated and that the connection is coming from a daemon.
2. Next, the server validates the scheduler name via find_sched(); if no scheduler is found with the specified name, the request is rejected.
3. If the scheduler is already connected, the server rejects the request.
4. If a scheduler with the specified name is found, temporarily store the current connection file descriptor in the scheduler object; later this will become the primary connection and be used to accept the current request.
5. When the second register scheduler batch request is received for same scheduler object, the server again authenticates the connection and validates the scheduler name and user.
6. The server checks for a temporary stored connection; if there is no temporary stored connection found, the server rejects the request.
7. The server validates that the second connection is not the same as the first connection; if both are the same connection, the server rejects the request.
8. The server validates that both connections come from the same host; if connections are not from the same host, the server rejects the request.
9. The server checks that the connection host is identical to the value of sched_host set by the administrator on the scheduler object; if they are not identical, the server rejects the request.
10. If all tests are passed, the server accepts the request, promotes the client as a scheduler, and assigns the first connection as primary connection and the second connection as secondary connection to the scheduler object.

22.8.1.2 Scheduling Cycle

If a scheduler's scheduling attribute is *True*, the server sends scheduling commands to that scheduler.

A scheduler runs in a loop. Inside each loop, it starts up, performs all of its work, and then stops. The scheduling cycle is triggered by a timer and by several possible events.

When there are no events to trigger the scheduling cycle, it is started by a timer. The time between starts is set in each scheduler's scheduler_iteration server attribute. The default value is 10 minutes.

The maximum duration of the cycle is set in each scheduler's sched_cycle_length attribute. A scheduler will terminate its cycle if the duration of the cycle exceeds the value of the attribute. The default value for the length of the scheduling cycle is 20 minutes. A scheduler does not include the time it takes to query dynamic resources in its cycle measurement.

22.8.1.3 Triggers for Scheduling Cycle

A scheduler starts when the following happen:

- The specified amount of time has passed since the previous start
- A job is submitted
- A job finishes execution.
- A new reservation is created
- A reservation starts
- Scheduling is enabled
- The server comes up
- A job is qrun
- A queue is started
- A job is moved to a local queue
- Eligible wait time for jobs is enabled
- A reservation is re-confirmed after being degraded
- A hook restarts the scheduling cycle

22.8.2 File Staging

PBS provides staging in before execution and staging out after execution. These services are requested via the `-W` option, which sets the stagein and stageout job attributes. The attributes specify the files to be staged:

-W stagein=<execution path>@<input file storage host>:<input file storage path>[,...]

-W stageout=<execution path>@<output file storage host>:<output file storage path>[,...]

The name *execution path* is the name of the file in the job's staging and execution directory (on the execution host). The *execution path* can be relative to the job's staging and execution directory, or it can be an absolute path.

The '@' character separates the execution specification from the storage specification.

The name *storage path* is the file name on the host specified by *storage host*. For stagein, this is the location where the input files come from. For stageout, this is where the output files end up when the job is done. The user must specify a hostname. The name can be absolute, or it can be relative to your home directory on the machine named *storage host*.

For stagein, the direction of travel is **from** *storage path* **to** *execution path*.

For stageout, the direction of travel is **from** *execution path* **to** *storage path*.

A request to stage in a file tells the server to direct MoM to copy a file from the storage location to the execution location. The user must have authority to access the file under the same username under which the job will be run. The storage file is not modified or destroyed. The file will be available before the job is initiated. If a file cannot be staged in for any reason, any files which were staged in are deleted and the job is placed in the wait state and mail is sent to the job owner.

A request to stage out a file tells the server to direct MoM to move a file from the execution location to the storage location. This service is performed after the job has completed execution and regardless of job exit status. If a file cannot be moved, mail is sent to the job owner. If a file is successfully staged out, the local file is deleted.

For file copy mechanism information, see "Setting File Transfer Mechanism" on page 441 in the PBS Professional Administrator's Guide.

22.8.3 Job Start

The server receives *Run Job* requests from a PBS scheduler and the `qrun` command. If a request is authenticated, the server forwards the *Run Job* request to the primary MoM for the job; the primary MoM is chosen by the scheduler or specified in the *Run Job* request.

See the sequence of events in "Sequence of Events for Start of Job" on page 477 in the PBS Professional Administrator's Guide.

The primary MoM creates a session leader that runs the shell program specified in the job's Shell_Path_List attribute.

The pathname of the script and any script arguments are passed as parameters to the shell. If the pathname of the shell is relative, the MoM searches its execution path, $PATH, for the shell. If the pathname of the shell is omitted or is the null string, the MoM uses the login shell for the job owner.

The MoM determines the job owner using the following rules:

1. Choose the username in the User_List job attribute whose hostname matches the execution host.
2. Choose the username in the User_List job attribute which has no associated hostname.
3. Use the username from the Job_Owner job attribute.

The MoM creates and sets the following environment variables in the environment of the session leader of the job:

- PBS_ENVIRONMENT; value set to the string "PBS_BATCH"
- PBS_QUEUE; value set to the name of the execution queue

PBS provides each job with environment variables where the job runs. PBS takes some from the submission environment, and creates others. Job submitters can create environment variables for their jobs. The environment variables created by PBS begin with "PBS_". The environment variables that PBS takes from the job submission environment begin with "PBS_O_".

For example, here are a few of the environment variables that accompany a job submitted by user1, with typical values:

```
PBS_O_HOME=/u/user1
PBS_O_LOGNAME=user1
PBS_O_PATH=/usr/bin:/usr/local/bin:/bin
PBS_O_SHELL=/bin/tcsh
PBS_O_HOST=host1
PBS_O_WORKDIR=/u/user1
PBS_JOBID=16386.server1
```

For a complete list of PBS environment variables, "PBS Environment Variables" on page 397 of the PBS Professional Reference Guide.

The MoM puts all of the variables found in the job's Variable_List attribute, with their corresponding values, into the environment of the job's session leader.

The MoM places the specified limits on host-level resources.

If the job has been run before and is now being rerun, the MoM will ensure that the standard output and standard error streams of the job are appended to the prior streams, if any.

If the MoM and host system support accounting, the MoM will use the value of the Account_Name job attribute as required by the host system.

If the MoM and host system support checkpoint, the MoM will set up checkpointing of the job according to the value of the Checkpoint job attribute. If checkpoint is supported and the Checkpoint attribute requests checkpointing at the minimum interval or at an interval less than the minimum interval for the queue, then checkpoint will be set for an interval given by the queue attribute checkpoint_min.

The MoM will set up the standard output stream and the standard error stream of the job according to the table labeled "How k, sandbox, o, and e Options to qsub Affect stdout and stderr", on page 43 of the PBS Professional User's Guide.

22.8.4 Job Routing

The PBS server performs all job routing tasks. Job routing is described in "Routing Queues" on page 27 in the PBS Professional Administrator's Guide.

If the routing destination is at another server, the current server uses a *Queue Job* request to move the job to the new destination.

22.8.5 Job Exit

When the session leader of a batch job exits, the MoM will perform the following actions in the order listed:

- Place the job in the exiting state.
- Manage the output and error streams of the job, according to "How k, sandbox, o, and e Options to qsub Affect stdout and stderr", on page 43 of the PBS Professional User's Guide.
- If the Mail_Points job attribute contains the value e (*EXIT)*, the server will send mail to the users listed in the Mail_Users job attribute.
- Files are staged out
- Frees the resources allocated to the job. The actual releasing of resources assigned to the processes of the job is performed by the kernel. PBS will free the resources which it reserved for the job by decrementing the resources_used generic data item for the queue and server.
- The job will be removed from the execution queue.

22.8.6 Aborting Job

If the server aborts a job and the Mail_Points job attribute contains the value *a (ABORT)*, the server will send mail to the users listed in the Mail_Users job attribute. The mail message will contain the reason the job was aborted.

22.8.7 Timed Events

The server performs certain events at a specified time or after a specified time delay. Examples:

- A job may have its Execution_Time attribute set to a time in the future. When that time is reached, the job state is updated.
- If the server is unable to make connection with another server, it is to retry after a time specified by the routing queue attribute route_retry_time.

22.8.8 Event Logging

The PBS server maintains an event logfile, the format and contents of which are documented in "Event Logging" on page 428 in the PBS Professional Administrator's Guide.

22.8.9 Accounting

The PBS server maintains an accounting file, the format and contents of which are documented in "Accounting" on page 529 in the PBS Professional Administrator's Guide.

22.9 Resource Management

PBS performs resource allocation at job initiation in two ways depending on the support provided by the host system. Resources are either reservable or non reservable.

22.9.1 Resource Limits

A job submitter can specify limits for resources used by their job, by requesting those amounts. If the job exceeds those limits, it is aborted. The administrator can specify default limits for resource use by jobs. Defaults are specified at the server and at queues. Defaults are applied when limits are not specified by the submitter. The administrator can also use hooks to set resource requests, and thereby limits, in whatever way is useful. See "Allocating Default Resources to Jobs" on page 244 in the PBS Professional Administrator's Guide and the *PBS Professional Plugins (Hooks) Guide*.

If the submitter does not specify a limit for a resource and there is no default, the job can use an unlimited amount of the resource.

22.9.2 Resource Names

For additional information, see "List of Built-in Resources" on page 259 of the PBS Professional Reference Guide where all resource names are documented.

22.10 Network Protocol

The PBS system fits into a client - server model, with a batch client making a request of a batch server and the server replying. This client - server communication necessitates an interprocess communication method and a data exchange (data encoding) format. Since the client and server may reside on different systems, the interprocess communication must be supportable over a network.

While the basic PBS system fits nicely into the client - server model, it also has aspects of a transaction system. When jobs are being moved between servers, it is critical that the jobs are not lost or replicated. Updates to a batch job must be applied once and only once. Thus the operation must be atomic. Most of the client to server requests consist of a single message. Treating these requests as an atomic operation is simple. One request, "Queue Job", is more complex and involves several messages, or subrequests, between the client and the server. Any of these subrequests might be rejected by the server. It is important that either side of the connection be able to abort the request (transaction) without losing or replicating the job. The network connection also might be lost during the request. Recovery from a partially transmitted request sequence is critical. The sequence of recovery from lost connections is discussed in the Queue Job Request description.

The batch system data exchange protocol must be built on top of a reliable stream connection protocol. PBS uses TCP/IP and the socket interface to the network. Either the Simple Network Interface, SNI, or the Detailed Network Interface, DNI, as specified by POSIX.12, Protocol Independent Interfaces, could be used as a replacement.

22.10.1 General DIS Data Encoding

The purpose of the "Data is Strings" encoding is to provide a simple, fast, small, machine-independent form for encoding data to a character string and back again. Because data can be decoded directly into the final internal data structures, the number of data copy operations are reduced. Data items are represented as people think of them, but preceded with a count of the length of each data item.

For small positive integers, it is impossible to tell from the encoded data whether they came from signed or unsigned chars, shorts, ints, or longs. Similarly, for small negative numbers, the only thing that can be determined from the encoded data is that the source datum was not unsigned. It is impossible to tell the word size of the encoding machine, or whether it uses 2's complement, one's complement or sign - magnitude representation, or.even if it uses binary arithmetic. All of the basic C data types are handled. Signed and unsigned chars, shorts, ints, longs produce integers. NULL-terminated and counted strings produce counted strings (with the terminating NULL removed). Floats, doubles, and long doubles produce real numbers. Complex data must be built up from the basic types. Note that there is no type tagging, so the type and sequence of data to be decoded must be known in advance.

23 Developer Headers and Libraries

23.1 Location of API Libraries

All of the libraries containing the PBS API are installed by default in *$PBS_EXEC/lib/*.

23.2 Location of Header Files

Header files used by your code are found in `$PBS_EXEC/include`.

23.3 Developer Package

We provide a development package as an RPM package. The files in this package are useful only for developing and compiling software that interfaces with PBS. They are not required to run PBS.

The development package is named `pbspro-devel` and contains the following headers and libraries:

```
/opt/pbs/include/pbs_error.h
/opt/pbs/include/pbs_ifl.h
/opt/pbs/include/rm.h
/opt/pbs/include/tm.h
/opt/pbs/include/tm_.h
/opt/pbs/lib/libattr.a
/opt/pbs/lib/liblog.a
/opt/pbs/lib/libnet.a
/opt/pbs/lib/libpbs.a
/opt/pbs/lib/libpbs_sched.a
/opt/pbs/lib/libsite.a
```

These files were previously in the `pbspro-server`, `pbspro-client` and `pbspro-execution` packages.

The `pbspro-devel` package also contains the `README` file, like the other PBS Professional RPM packages:

```
/usr/share/doc/pbspro-devel-19.0.0/README.md
```

You can install the `pbspro-devel` package separately from the other PBS packages. This package does not conflict with other PBS packages.

23.4 Batch Interface Library

The primary external application programming interface to PBS is the Batch Interface Library, or IFL. This library provides all of the batch service requests used for PBS. The IFL provides a user-callable function corresponding to each batch client command in PBS Professional. Each command generates its own batch service request. You request service from a batch server by calling the appropriate library routine and passing it the required arguments.

The user-callable routines are declared in the header file `PBS_ifl.h`.

We describe the Batch Interface Library in section , “Batch Interface Library (IFL)”, on page 21.

23.4.1 Error Codes

Error codes are available in the header file `PBS_error.h`.

23.4.2 Windows Requirement

To use `pbs_connect()` with Windows, initialize the network library and link with `winsock2`. Call `winsock_init()` before calling `pbs_connect()`, and link against the `ws2_32.lib` library.

23.5 Example Compilation Line

A compile command might look like the following:

```
cc mycode.c -I/usr/pbs/include -L/usr/pbs/lib -lpbs
```

24
Batch Interface Library (IFL)

You can use the commands in this library to build your new batch clients. For example, you can customize your job status display instead of using `qstat`, build new control commands, or use these commands to build jobs that can get their own status or spawn new jobs.

24.1 Interface Library Overview

The primary external application programming interface to PBS is the Batch Interface Library, or IFL. This library provides all of the batch service requests used for PBS. The IFL provides a user-callable function corresponding to each batch client command in PBS Professional. Each command generates its own batch service request. You request service from a batch server by calling the appropriate library routine and passing it the required arguments.

The user-callable routines are declared in the header file `PBS_ifl.h`.

Error codes are available in the header file `PBS_error.h`.

24.1.1 Connection to Server

We provide network connection management routines to be used with our API commands.

You open a connection with a batch server via a call to `pbs_connect()`, which returns a connection handle to the desired server. You can open multiple connections, and you can use each connection for multiple service requests.

When you are finished using a connection to the server, close it via a call to `pbs_disconnect()`.

24.1.2 Authentication

Before it establishes a connection, `pbs_connect()` `fork()`s and `exec()`s a `pbs_iff` process. The `pbs_iff` process provides a credential which validates the user's identity, and prevents a user from spoofing another user's identity. This credential is included in each batch request sent to the server, and consists of the following:

- The user's name from the password file based on running `pbs_iff's` "real uid" value
- The unprivileged, client-side port value associated with the original `pbs_connect()` request message to the server.

The server checks the entries in its connection table for a matching entry which is not yet marked authenticated. The server requires that the matching entry came from a privileged, remote-end, port value.

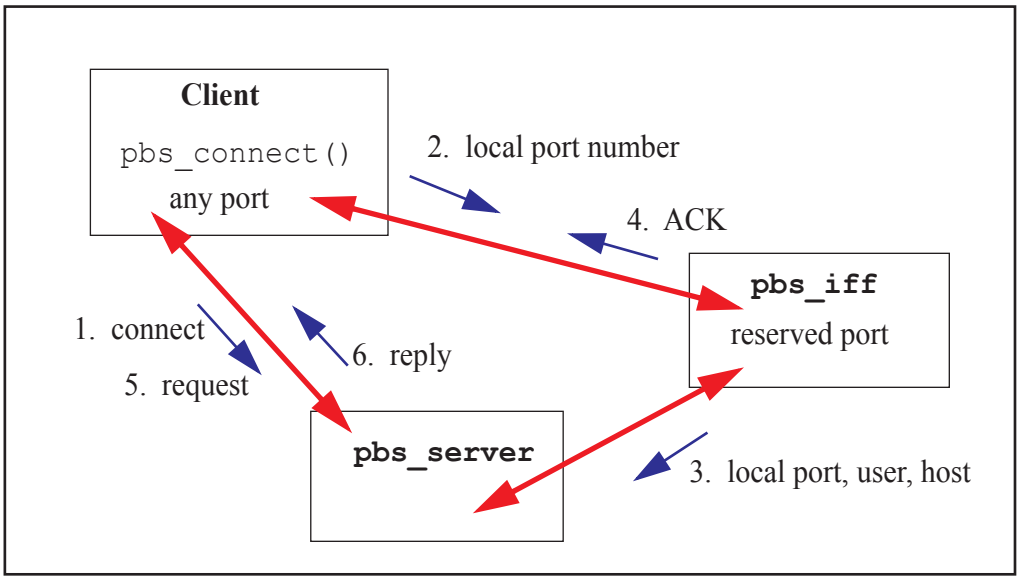

Figure 4-1: Interface Between Client, IFF, and Server

24.1.3 Windows Requirement

To use `pbs_connect()` with Windows, initialize the network library and link with `winsock2`. Call `winsock_init()` before calling `pbs_connect()`, and link against the `ws2_32.lib` library.

24.2 Batch Library Routines

24.3 pbs_alterjob

alter a PBS batch job

24.3.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_alterjob(int connect, char *jobID, struct attropl *change_list, char *extend)*

24.3.2 Description

Issues a batch request to alter a batch job.

This command generates a *Modify Job* (11) batch request and sends it to the server over the connection specified by connect.

Job state may affect which attributes can be altered. See "qalter" on page 130 of the PBS Professional Reference Guide.

24.3.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection over which to send batch request to server.

jobID

ID of job or job array to be altered. Format for a job:

<sequence number>.<server name>

Format for an array job:

<sequence number>[].<server name>

change_list

Pointer to a list of attributes to change. Each attribute is described in an attropl structure, defined in `pbs_ifl.h` as:

```
struct attropl {
        struct attropl *next;
        char *name;
        char *resource;
        char *value;
        enum batch_op op;
};
```

extend

Character string for extensions to command. Not currently used.

24.3.3.1 Members of attropl Structure

next

Points to next attribute in list. A null pointer terminates the list.

name

Points to a string containing the name of the attribute.

resource

Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a pointer to a null string.

If the resource is already present in the job's Resource_List attribute, the value is altered as specified. Otherwise the resource is added.

value

Points to a string containing the value of the attribute or resource.

op

Defines the operation to perform on the attribute or resource. For this command, operators are *SET*, *UNSET*, *INCR*, *DECR.*

24.3.4 Return Value

The routine returns *0* (*zero*) on success.

If an error occurred, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.3.5 See Also

qalter, qhold, qrls, qsub, pbs_connect, pbs_holdjob, pbs_rlsjob

24.4 pbs_asyrunjob

run an asynchronous PBS batch job

24.4.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_asyrunjob(int connect, char *jobID, char *location, char *extend)*

24.4.2 Description

Issues a batch request to run a batch job.

Generates an *Asynchronous Run Job* (23) request and sends it to the server over the connection specified by connect.

The server validates the request and replies before initiating the execution of the job.

You can use this version of the call to reduce latency in scheduling, especially when the scheduler must start a large number of jobs.

24.4.3 Required Privilege

You must have Manager or Operator privilege to use this command.

24.4.4 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

jobID

ID of job to be run.

Format for a job:

<sequence number>.<server name>

Format for a job array:

<sequence number>[].<server name>

location

Location where job should run, and optionally resources to use. Same as `qrun -H`:

-H <vnode specification without resources>

The *vnode specification without resources* has this format:

(<vchunk>)[+(<vchunk>) ...]

where *vchunk* has the format

<vnode name>[+<vnode name> ...]

Example:

```
-H (VnodeA+VnodeB)+(VnodeC)
```

PBS applies one requested chunk from the job's selection directive in round-robin fashion to each *vchunk* in the list. Each *vchunk* must be sufficient to run the job's corresponding chunk, otherwise the job may not execute correctly.

-H <vnode specification with resources>

The *vnode specification with resources* has this format:

(<vchunk>)[+(<vchunk>) ...]

where *vchunk* has the format

<vnode name>:<vnode resources>[+<vnode name>:<vnode resources> ...]

and where *vnode resources* has the format

<resource name>=<value>[:<resource name>=<value> ...]

Example:

```
-H (VnodeA:mem=100kb:ncpus=1) +(VnodeB:mem=100kb:ncpus=2+VnodeC:mem=100kb)
```

PBS creates a new selection directive from the *vnode specification with resources*, using it instead of the original specification from the user. Any single resource specification results in the job's original selection directive being ignored. Each *vchunk* must be sufficient to run the job's corresponding chunk, otherwise the job may not execute correctly.

If the job being run requests `-l place=exclhost`, take extra care to satisfy the `exclhost` request. Make sure that if any vnodes are from a multi-vnoded host, all vnodes from that host are allocated. Otherwise those vnodes can be allocated to other jobs.

extend

Character string for extensions to command. Not currently used.

24.4.5 Return Value

The routine returns *0* (*zero*) on success.

If an error occurred, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.4.6 See Also

qrun, pbs_connect, pbs_runjob

24.5 pbs_confirmresv

confirm a PBS reservation

24.5.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_confirmresv(int connect, char *reservationID, char *location, unsigned long start_time, char *extend)*

24.5.2 Description

Issues a batch request to confirm a PBS advance, standing, or maintenance reservation.

This function generates a *Confirm Reservation* (75) batch request and sends it to the server over the connection specified by connect.

24.5.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection over which to send batch request to server.

reservationID

Reservation to be confirmed.

Format for advance reservation:

R<sequence number>.<server name>

Format for standing reservation:

S<sequence number>.<server name>

Format for maintenance reservation:

M<sequence number>.<server name>

location

String describing vnodes and resources to be used for reservation. Format:

(<vchunk>)[+(<vchunk>) ...]

where *vchunk* has the format

<vnode name>:<vnode resources>[+<vnode name>:<vnode resources> ...]

and where *vnode resources* has the format

<resource name>=<value>[:<resource name>=<value> ...]

Example:

```
-H (VnodeA:mem=100kb:ncpus=1) +(VnodeB:mem=100kb:ncpus=2+VnodeC:mem=100kb)
```

start_time

Unsigned long containing start time in seconds since epoch. Used only for ASAP reservations (reservations created by using `pbs_rsub -W qmove=<jobID>` on an existing job).

extend

Character string for specifying confirmation/non-confirmation action:

- To confirm a normal reservation, pass in *PBS_RESV_CONFIRM_SUCCESS*.
- To have an unconfirmed reservation deleted, pass in *PBS_RESV_CONFIRM_FAIL*.
- To have the scheduler set the time when it will try to reconfirm a degraded reservation, pass in *PBS_RESV_CONFIRM_FAIL*.

24.5.4 Return Value

The routine returns *0* (*zero*) on success.

If an error occurred, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.5.5 See Also

pbs_rsub, pbs_connect

24.6 pbs_connect

return a connection handle from a PBS batch server

24.6.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_connect(char *server)*

24.6.2 Description

This function establishes a virtual stream (TCP/IP) connection with the specified batch server.

Returns a connection handle.

`pbs_connect()` determines whether or not the complex has a failover server configured. It also determines which server is the primary and which is the secondary.

24.6.3 Arguments

server

Specifies name of server to connect to. Format:

<hostname>[:<port>]

If you do not specify a port, PBS uses the default.

If *server* is a null pointer or a null string, this function opens a connection to the default server. The default server is specified in the PBS_DEFAULT environment variable or the PBS_SERVER parameter in `/etc/pbs.conf`.

24.6.4 Usage

Use this function to establish a connection handle to the desired server before calling any of the other `pbs_*` API functions. They will send their batch requests over the connection established by this function. You can send multiple requests over one connection.

24.6.5 Cleanup

After you are done using the connection handle, close the connection via a call to `pbs_disconnect()`.

24.6.6 Side Effects

The global variable *pbs_server* is declared in `pbs_ifl.h`. This variable is set on return to point to the server name to which `pbs_connect()` connected or attempted to connect.

24.6.7 Windows Requirement

In order to use `pbs_connect()` with Windows, initialize the network library and link with `winsock2`. To do this, call `winsock_init()` before calling `pbs_connect()`, and link against the `ws2_32.lib` library.

24.6.8 Return Value

On success, the routine returns a connection handle which is a non-negative integer.

If an error occurred, the routine returns -1, and the error number is available in the global integer pbs_errno.

24.6.9 See Also

qsub, pbs_alterjob, pbs_deljob, pbs_disconnect, pbs_geterrmsg, pbs_holdjob, pbs_locjob, pbs_manager, pbs_modify_resv, pbs_movejob, pbs_msgjob, pbs_rerunjob, pbs_rlsjob, pbs_runjob, pbs_selectjob, pbs_selstat, pbs_sigjob, pbs_statjob, pbs_statque, pbs_statresv, pbs_statsched, pbs_statserver, pbs_submit, pbs_submit_resv, pbs_terminate, pbs_server

24.7 pbs_default

return the name of the default PBS server

24.7.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*char *pbs_default()*

24.7.2 Description

Returns a pointer to a character string containing the name of the default PBS server.

The default server is specified in the PBS_DEFAULT environment variable or the PBS_SERVER parameter in `/etc/pbs.conf`.

24.7.3 Return Value

On success, returns a pointer to a character string containing the name of the default PBS server. You do not need to free the character string.

Returns null if it cannot determine the name of the default server.

24.8 pbs_deljob

delete a PBS batch job

24.8.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_deljob(int connect, char *jobID, char *extend)*

24.8.2 Description

Issues a batch request to delete a batch job.

This function generates a *Delete Job* (6) batch request and sends it to the server over the connection specified by connect.

If the batch job is running, the MoM sends the SIGTERM signal followed by SIGKILL.

If the batch job is deleted by a user other than the job owner, PBS sends mail to the job owner.

24.8.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection over which to send batch request to server.

jobID

ID of job, job array, subjob, or range of subjobs to be deleted.

Format for a job:

<sequence number>.<server name>

Format for an array job:

<sequence number>[].<server name>

Format for a subjob:

<sequence number>[<index>][.<server name>]

Format for a range of subjobs:

<sequence number>[<first>-<last>][.<server name>]

extend

Character string for extensions to command. If the string is not null, it is appended to the message mailed to the job owner.

24.8.4 Return Value

The routine returns *0* (*zero*) on success.

On error, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.8.5 See Also

qdel, pbs_connect

24.9 pbs_delresv

delete a reservation

24.9.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_delresv(int connect, char *reservationID, char *extend)*

24.9.2 Description

Issues a batch request to delete a reservation.

This function generates a *Delete Reservation* (72) batch request and sends it to the server over the connection specified by connect.

If the reservation is in state *RESV_RUNNING*, and there are jobs in the reservation queue, those jobs are deleted before the reservation is deleted.

24.9.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection over which to send batch request to server.

reservationID

Reservation to be deleted.

Format for advance reservation:

R<sequence number>.<server name>

Format for standing reservation:

S<sequence number>.<server name>

Format for maintenance reservation:

M<sequence number>.<server name>

extend

Character string for extensions to command. Not currently used.

24.9.4 Return Value

The routine returns *0* (*zero*) on success.

On error, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.9.5 See Also

pbs_rdel, pbs_connect

24.10 pbs_disconnect

disconnect from a PBS batch server

24.10.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

int pbs_disconnect(int connect)

24.10.2 Description

Closes the virtual stream connection to a PBS batch server. Connection was previously returned from a call to `pbs_connect()`.

24.10.3 Arguments

connect

Connection handle to be closed. Return value of `pbs_connect()`. Specifies connection used earlier to send batch requests to server.

24.10.4 Return Value

The routine returns *0* (*zero*) after successfully closing the connection.

If an error occurred, the routine returns -1, and the error number is available in the global integer pbs_errno.

24.10.5 See Also

pbs_connect

24.11 pbs_geterrmsg

get error message for most recent PBS batch operation

24.11.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*char *pbs_geterrmsg(int connect)*

24.11.2 Description

Returns most recent error message text associated with a batch server request.

If a preceding batch interface library call over the connection specified by connect returned an error from the server, the server may have created an associated text message. If there is a text message, this function returns a pointer to the text message.

24.11.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to request error message from server.

24.11.4 Return Value

If the server returned an error and created an error text string in reply to a previous batch request, this function returns a pointer to the text string. The text string is null-terminated.

If the server does not have an error text string, this function returns a null pointer.

The text string is a global variable; you do not need to free it.

24.11.5 See Also

pbs_connect

24.12 pbs_holdjob

place a hold on a PBS batch job

24.12.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_holdjob(int connect, char *jobID, char *hold_type, char *extend)*

24.12.2 Description

Issues a batch request to place a hold on a job or job array.

This function generates a *Hold Job* (7) batch request sends it to the server over the connection specified by connect.

24.12.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection over which to send batch request to server.

jobID

ID of job which is to be held.

Format for a job:

<sequence number>.<server name>

Format for a job array:

<sequence number>[].<server name>

hold_type

Type of hold to apply to job or job array. Valid values are defined in `pbs_ifl.h`. If *hold_type* is a null pointer or points to a null string, PBS applies a *User* hold to the job or job array.

extend

Character string for extensions to command. Not currently used.

24.12.4 Return Value

The routine returns *0* (*zero*) on success.

If an error occurred, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.12.5 See Also

qhold, pbs_connect, pbs_alterjob, pbs_rlsjob

24.13 pbs_locjob

return current location of a PBS batch job

24.13.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*char *pbs_locjob(int connect, char *jobID, char *extend)*

24.13.2 Description

Issues a batch request to locate a batch job or job array.

This function generates a *Locate Job* (8) batch request and sends it to the server over the connection specified by connect.

If the server currently manages the batch job, or knows which server does currently manage the job, the server returns the location of the job.

24.13.3 Arguments

connect
: Return value of `pbs_connect()`. Specifies connection over which to send batch request to server.

jobID
: ID of job to be located.

Format for a job:

<sequence number>.<server name>

Format for a job array:

<sequence number>[].<server name>

extend
: Character string for extensions to command. Not currently used.

24.13.4 Cleanup

The character string returned by `pbs_locjob()` is allocated by `pbs_locjob()`. You must free it via a call to `free()`.

24.13.5 Return Value

On success, returns a pointer to a character string containing current location. Format:

<server name>

On failure, returns a null pointer, and the error number is available in the global integer pbs_errno.

24.13.6 See Also

pbs_connect

24.14 pbs_manager

modify a PBS batch object

24.14.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_manager(int connect, int command, int object_type, char *object_name, struct attropl *attrib_list, char *extend)*

24.14.2 Description

Issues a batch request to perform administrative functions at a server.

Generates a *Manager* (9) batch request and sends it to the server over the connection specified by connect.

You can use this to create, delete, and set attributes of objects such as queues.

24.14.3 Required Privilege

This function requires Manager or Operator privilege depending on the operation, and root privilege when used with hooks.

When not used with hooks:

- Functions MGR_CMD_CREATE and MGR_CMD_DELETE require PBS Manager privilege.
- Functions MGR_CMD_SET and MGR_CMD_UNSET require PBS Manager or Operator privilege.

When used with hooks:

- All commands require root privilege on the server host.
- Functions MGR_CMD_IMPORT, MGR_CMD_EXPORT, and MGR_OBJ_HOOK are used only with hooks, and therefore require root privilege on the server host.
- Hook commands are run at the server host.

24.14.4 Arguments

connect
: Return value of `pbs_connect()`. Specifies connection over which to send batch request to server.

command
: Operation to be performed. Valid values are specified in `pbs_ifl.h`.

object_type
: Specifies type of object on which command is to operate. Valid values are specified in `pbs_ifl.h`.

object_name
: Name of object on which to operate.

attrib_list

Pointer to a list of attributes to be operated on. Each attribute is described in an attropl structure, defined in pbs_ifl.h as:

```
struct attropl {
        struct attropl *next;
        char *name;
        char *resource;
        char *value;
        enum batch_op op;
};
```

extend

Character string for extensions to command. Not currently used.

24.14.4.1 Members of attropl Structure

next

Points to next attribute in list. A null pointer terminates the list.

name

Points to a string containing the name of the attribute.

resource

Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

If the resource is already present in the object's attribute, the value is altered as specified. Otherwise the resource is added.

value

Points to a string containing the new value of the attribute or resource. For parameterized limit attributes, this string contains all parameters for the attribute.

op

Defines the manner in which the new value is assigned to the attribute or resource. The operators used for this function are *SET*, *UNSET*, *INCR*, *DECR*.

24.14.5 Usage for Hooks

When importing a hook or hook configuration file:

- Set *command* to *MGR_CMD_IMPORT*
- Set *object_type* to *SITE_HOOK* (or *PBS_HOOK* if you are importing a configuration file for a built-in hook; you cannot import a built-in hook)
- Set *object_name* to the name of the hook
- In one attropl structure:
  - Set *name* to "*content-type*"
  - Set *value* to "*application/x-python*" for a hook, or "*application/x-config*" for a configuration file
- In another attropl structure:
  - Set *name* to "*content-encoding*"
  - Set *value* to "*default*" or "*base64*"
- In a third attropl structure:
  - Set *name* to "*input-file*"
  - Set *value* to the name of the input file
- Set *op* to *SET*

When exporting a hook or hook configuration file:

- Set *command* to *MGR_CMD_EXPORT*
- Set *object_type* to *SITE_HOOK* (or *PBS_HOOK* if you are exporting a configuration file for a built-in hook; you cannot export a built-in hook)
- Set *object_name* to the name of the hook
- In one attropl structure:
  - Set *name* to "*content-type*"
  - Set *value* to "*application/x-python*" for a hook, or "*application/x-config*" for a configuration file
- In another attropl structure:
  - Set *name* to "*content-encoding*"
  - Set *value* to "*default*" or "*base64*"
- In a third attropl structure:
  - Set *name* to "*output-file*"
  - Set *value* to the name of the output file
- Set *op* to *SET*

See the *PBS Professional Hooks Guide*.

24.14.6 Return Value

The routine returns *0* (*zero*) on success.

If an error occurred, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.14.7 See Also

qmgr, pbs_connect

24.15 pbs_modify_resv

modify a PBS reservation

24.15.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*char *pbs_modify_resv(int connect, char *reservationID, struct attropl *attrib_list, char *extend)*

24.15.2 Description

Issues a batch request to modify a reservation.

Generates a *Modify Reservation* (91) batch request and sends it to the server over the connection specified by connect.

24.15.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection over which to send batch request to server.

reservationID

Reservation to be modified.

Format for advance reservation:

R<sequence number>.<server name>

Format for standing reservation:

S<sequence number>.<server name>

attrib_list

Pointer to a list of attributes to modify. Each attribute is described in an attropl structure, defined in `pbs_ifl.h` as:

```
struct attropl {
        struct attropl *next;
        char *name;
        char *resource;
        char *value;
        enum batch_op op;
};
```

For any attribute that is not specified or that is a null pointer, PBS takes the default action for that attribute. The default action is to assign the default value or to not pass the attribute with the reservation; the action depends on the attribute.

extend

Character string for extensions to command. Not currently used.

24.15.3.1 Members of attropl Structure

next

Points to next attribute in list. A null pointer terminates the list.

name

Points to a string containing the name of the attribute.

resource

Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

If the resource is already present in the reservation's Resource_List attribute, the value is altered as specified. Otherwise the resource is added.

value

Points to a string containing the value of the attribute or resource.

op

Operator. The only allowed operator for this function is *SET*.

24.15.4 Return Value

On success, returns a character string containing the reservation ID assigned by the server.

On failure, returns a null pointer, and the error number is available in the global integer pbs_errno.

24.15.5 Cleanup

The space for the reservation ID string is allocated by `pbs_modify_resv()`.

Release the reservation ID via a call to `free()` when no longer needed.

24.15.6 See Also

pbs_rsub, pbs_connect

24.16 pbs_movejob

move a PBS batch job to a new destination

24.16.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_movejob(int connect, char *jobID, char *destination, char *extend)*

24.16.2 Description

Issues a batch request to move a job or job array to a new destination.

Generates a *Move Job* (12) batch request and sends it to the server over the connection specified by connect.

Moves specified job or job array from its current queue and server to the specified queue and server.

You cannot move a job in the Running, Transiting, or Exiting states.

24.16.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection over which to send batch request to server.

jobID

ID of job to be moved.

Format for a job:

<sequence number>.<server name>

Format for a job array:

<sequence number>[].<server name>

destination

New location for job or job array. Formats:

<queue name>@<server name>

Specified queue at specified server

<queue name>

Specified queue at default server

@<server name>

Default queue at specified server

@default

Default queue at default server

(null pointer or null string)

Default queue at default server

extend

Character string for extensions to command. Not currently used.

24.16.4 Return Value

The routine returns *0* (*zero*) on success.

If an error occurred, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.16.5 See Also

qmove, pbs_connect

24.17 pbs_msgjob

record a message for a running PBS batch job

24.17.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_msgjob(int connect, char *jobID, int file, char *message, char *extend)*

24.17.2 Description

Issues a batch request to write a message in one or more output files of a batch job.

Generates a *Message Job* (10) batch request and sends it to the server over the connection specified by connect.

You can write a message into a job's `stdout` and/or `stderr` files. Can be used on jobs or subjobs, but not job arrays or ranges of subjobs.

24.17.3 Arguments

connect
: Return value of `pbs_connect()`. Specifies connection over which to send batch request to server.

jobID
: ID of job into whose output file(s) to write.

Format for a job:

<sequence number>.<server name>

Format for a subjob:

<sequence number>[<index>].<server name>

file
: Indicates whether to write to `stdout`, `stderr`, or both:

1
: Writes to `stdout`

2
: Writes to `stderr`

3
: Writes to `stdout` and `stderr`

message
: Character string to be written to output file(s).

extend
: Character string for extensions to command. Not currently used.

24.17.4 Return Value

The routine returns *0* (*zero*) on success.

If an error occurred, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.17.5 See Also

qmsg, pbs_connect

24.18 pbs_orderjob

swap positions of two PBS batch jobs

24.18.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_orderjob(int connect, char *jobID1, char *jobID2, char *extend)*

24.18.2 Description

Issues a batch request to swap the positions of two jobs.

Generates an *Order Job* (50) batch request and sends it to the server over the connection specified by connect.

Can be used on jobs and job arrays. Can be used on jobs in different queues. Both jobs must be at the same server.

You cannot swap positions of jobs that are running.

24.18.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection over which to send batch request to server.

jobID1, jobID2

IDs of jobs to be swapped.

Format for a job:

<sequence number>.<server name>

Format for a job array:

<sequence number>[].<server name>

extend

Character string for extensions to command. Not currently used.

24.18.4 Return Value

The routine returns *0* (*zero*) on success.

If an error occurred, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.18.5 See Also

qmove, qorder, qsub, pbs_connect

24.19 pbs_preempt_jobs

preempt a list of jobs

24.19.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*preempt_job_info *pbs_preempt_jobs(int connect, char **jobID_list)*

24.19.2 Description

Sends the server a list of jobs to be preempted.

Sends a *Preempt Jobs* (93) batch request to the server over the connection specified by connect.

Returns a list of preempted jobs along with the method used to preempt each one.

24.19.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

jobID_list

List of job IDs to be preempted, as a null-terminated array of pointers to strings.

Format for a job ID:

<sequence number>.<server name>

Format for a job array ID:

<sequence number>[].<server name>

For example:

```
const char *joblist[3];
joblist[0]="123.myserver";
joblist[1]="456.myserver";
joblist[2]=NULL;
```

24.19.4 Return Value

Returns a list of preempted jobs. Each job is represented in a preempt_job_info structure, which has the following fields:

job_id

The job ID, in a char*

preempt_method

How the job was preempted, in a char:

S

The job was preempted using suspension.

C

The job was preempted using checkpointing.

R
: The job was preempted by being requeued.

D
: The job was preempted by being deleted.

0 (zero)
: The job could not be preempted.

24.19.5 Cleanup

You must free the list of preempted jobs by passing it directly to `free()`.

24.20 pbs_relnodesjob

release some or all of the non-primary-execution-host vnodes assigned to a PBS job

24.20.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_relnodesjob (int connect, char *jobID, char *vnode_list, char *extend)*

24.20.2 Description

Issues a batch request to release some or all of the vnodes of a batch job. Generates a *RelnodesJob* (90) batch request and sends it to the server over the connection specified by connect.

You cannot release vnodes on the primary execution host.

Do not use when MPI processes are running on a host managed by the cgroups hook. Use when MPI processes are not running.

You can use this on jobs and subjobs, but not on job arrays or ranges of subjobs.

24.20.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

jobID

ID of job or subjob whose vnodes are to be released.

Format for a job:

<sequence number>.<server name>

Format for a subjob:

<sequence number>[<index>].<server name>

vnode_list

List of vnode names separated by plus signs ("+").

If *vnode_list* is a null pointer, this specifies that all the vnodes assigned to the job that are not on the primary execution host are to be released.

extend

Character string for extensions to command. Not currently used.

24.20.4 Return Value

On success, returns *0* (*zero*).

On error, returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.20.5 See Also

pbs_connect

24.21 pbs_rerunjob

requeue a PBS batch job

24.21.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_rerunjob(int connect, char *jobID, char *extend)*

24.21.2 Description

Issues a batch request to requeue a batch job, job array, subjob, or range of subjobs.

Generates a *Rerun Job* (14) batch request and sends it to the server over the connection specified by connect.

You cannot requeue a job that is marked as not rerunnable (the Rerunable attribute is *False*).

24.21.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

jobID

ID of job to be requeued.

Format for a job:

<sequence number>.<server name>

Format for a job array:

<sequence number>[].<server name>

Format for a subjob:

<sequence number>[<index>].<server name>

Format for a range of subjobs:

<sequence number>[<index start>-<index end>].<server name>

extend

Character string for extensions to command. Not currently used.

24.21.4 Return Value

The routine returns *0* (*zero*) on success.

If an error occurred, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.21.5 See Also

qrerun, pbs_connect

24.22 pbs_rlsjob

release a hold on a PBS batch job

24.22.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_rlsjob(int connect, char *jobID, char *hold_type, char *extend)*

24.22.2 Description

Issues a batch request to release a hold on a job or job array.

Generates a *Release Job* (13) batch request and sends it to the server over the connection specified by connect.

24.22.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection over which to send batch request to server.

jobID

ID of job which is to have a hold released.

Format for a job:

<sequence number>.<server name>

Format for a job array:

<sequence number>[].<server name>

hold_type

Type of hold to remove from job or job array. Valid values are defined in `pbs_ifl.h`. If *hold_type* is a null pointer or points to a null string, PBS removes a *User* hold from the job or job array.

extend

Character string for extensions to command. Not currently used.

24.22.4 Return Value

The routine returns *0* (*zero*) on success.

If an error occurred, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.22.5 See Also

qhold, qrls, pbs_connect, pbs_holdjob

24.23 pbs_runjob

run a PBS batch job

24.23.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_runjob(int connect, char *jobID, char *location, char *extend)*

24.23.2 Description

Issues a batch request to run a batch job.

Generates a *Run Job* (15) batch request and sends it to the server over the connection specified by connect.

If no file stagein is required, the server replies when the job has started execution. If file stagein is required, the server replies when staging is started.

24.23.3 Required Privilege

You must have Operator or Administrator privilege to use this command.

24.23.4 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

jobID

ID of job to run.

Format for a job:

<sequence number>.<server name>

Format for a job array:

<sequence number>[].<server name>

location

Location where job should run, and optionally resources to use. Same as `qrun -H`:

-H <vnode specification without resources>

The *vnode specification without resources* has this format:

(<vchunk>)[+(<vchunk>) ...]

where *vchunk* has the format

<vnode name>[+<vnode name> ...]

Example:

```
-H (VnodeA+VnodeB)+(VnodeC)
```

PBS applies one requested chunk from the job's selection directive in round-robin fashion to each *vchunk* in the list. Each *vchunk* must be sufficient to run the job's corresponding chunk, otherwise the job may not execute correctly.

-H <vnode specification with resources>

The *vnode specification with resources* has this format:

(<vchunk>)[+(<vchunk>) ...]

where *vchunk* has the format

<vnode name>:<vnode resources>[+<vnode name>:<vnode resources> ...]

and where *vnode resources* has the format

<resource name>=<value>[:<resource name>=<value> ...]

Example:

```
-H (VnodeA:mem=100kb:ncpus=1) +(VnodeB:mem=100kb:ncpus=2+VnodeC:mem=100kb)
```

PBS creates a new selection directive from the *vnode specification with resources*, using it instead of the original specification from the user. Any single resource specification results in the job's original selection directive being ignored. Each *vchunk* must be sufficient to run the job's corresponding chunk, otherwise the job may not execute correctly.

If the job being run requests `-l place=exclhost`, take extra care to satisfy the `exclhost` request. Make sure that if any vnodes are from a multi-vnoded host, all vnodes from that host are allocated. Otherwise those vnodes can be allocated to other jobs.

extend

Character string for extensions to command. Not currently used.

24.23.5 Return Value

The routine returns *0* (*zero*) on success.

If an error occurred, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.23.6 See Also

qrun, pbs_asyrunjob, pbs_connect

24.24 pbs_selectjob

select PBS batch jobs according to specified criteria

24.24.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*char **pbs_selectjob(int connect, struct attropl *criteria_list, char *extend)*

24.24.2 Description

`pbs_selectjob()` issues a batch request to select jobs that meet specified criteria, and returns an array of job IDs that meet the specified criteria.

This command generates a *Select Jobs* (16) batch request and sends it to the server over the connection handle specified by connect.

By default, `pbs_selectjob()` returns all batch jobs for which the user is authorized to query status. You filter the jobs by specifying values for job attributes and resources. You send a linked list of attributes with associated values and operators. Job attributes are listed in "Job Attributes" on page 327 of the PBS Professional Reference Guide.

Returns a list of jobs that meet all specified criteria.

24.24.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

criteria_list

Pointer to a list of attributes to use as selection criteria. Each attribute is described in an attropl structure, defined in `pbs_ifl.h` as:

```
struct attropl {
        struct attropl *next;
        char *name;
        char *resource;
        char *value;
        enum batch_op op;
};
```

If criteria_list itself is null, you are not using attributes or resources as selection criteria.

extend

Character string where you can specify limits or extensions of your search.

24.24.3.1 Members of attropl Structure

next

Points to next attribute in list. A null pointer terminates the list.

name

Points to a string containing the name of the attribute.

resource

Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

value

Points to a string containing the value of the attribute or resource.

op

Defines the operator in the logical expression:

<existing value> <operator> <specified limit>

Jobs for which the logical expression evaluates to *True* are selected.

For this command, op can be *EQ, NE, GE, GT, LE, LT.*

24.24.4 Querying States

You can select jobs in more than one state using a single request, by listing all states you want returned. For example, to get jobs in *Held* and *Waiting* states:

- Fill in criteria_list->name with "*job_state*"
- Fill in criteria_list->value with "*HW*" for *Held* and *Waiting*

24.24.5 Extending Your Query

You can use the following characters in the extend parameter:

T, t

Extends query to include subjobs. Job arrays are not included.

x

Extends query to include finished and moved jobs.

24.24.5.1 Querying Finished and Moved Jobs

To get information on finished or moved jobs, as well as current jobs, add an '*x*' character to the extend parameter (set one character to be the '*x*' character). For example:

```
pbs_selectjob ( ..., ..., <extend characters>) ...
```

To get information on finished jobs only:

- Add the '*x*' character to the extend parameter
- Fill in criteria_list->name with "*ATTR_state*"
- Fill in criteria_list->value with "*FM*" for *Finished* and *Moved*

Subjobs are not considered finished until the parent array job is finished.

24.24.5.2 Querying Job Arrays and Subjobs

To query only job arrays (not jobs or subjobs):

- Fill in criteria_list->name with "*array*"
- Fill in criteria_list->value with "*True*"

To query only job arrays and subjobs (not jobs):

- Fill in criteria_list->name with "*array*"
- Fill in criteria_list->value with "*True*"
- Add the '*T*' or '*t*' character to the extend parameter

To query only jobs and subjobs (not job arrays), add the '*T*' or '*t*' character to the extend parameter.

24.24.6 Return Value

The return value is a pointer to a null-terminated array of character pointers. Each character pointer in the array points to a character string which is a job ID in the form:

<sequence number>.<server>@<server>

If no jobs met the criteria, the first pointer in the array is null.

If an error occurred, the routine returns a null pointer, and the error number is available in the global integer pbs_errno.

24.24.7 Cleanup Required

The returned array of character pointers is malloc()'ed by `pbs_selectjob()`. When the array is no longer needed, you must free it via a call to `free()`.

24.24.8 See Also

pbs_alterjob, pbs_connect, qsig

24.25 pbs_selstat

get status of selected PBS batch jobs

24.25.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*struct batch_status *pbs_selstat(int connect, struct attropl *criteria_list, struct attrl *output_attribs, char *extend)*

24.25.2 Description

Issues a batch request to get the status of jobs which meet the specified criteria.

Generates a *Select Status* (51) batch request and sends it to the server over the connection specified by connect.

Returns a list of batch_status structures for jobs that meet the selection criteria.

This function is a combination of `pbs_selectjob()` and `pbs_statjob()`.

By default this gives status for all jobs for which you are authorized to query status. You can filter the results by specifying selection criteria.

24.25.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

criteria_list

Pointer to a list of selection criteria, which are attributes and resources with required values. If this list is null, you are not filtering your results via selection criteria. Each attribute or resource is described in an attropl structure, defined in `pbs_ifl.h` as:

```
struct attropl {
        struct attropl *next;
        char *name;
        char *resource;
        char *value;
        enum batch_op op;
};
```

If criteria_list itself is null, you are not using attributes or resources as selection criteria.

output_attribs

Pointer to a list of attributes to return. If this list is null, all attributes are returned. Each attribute is described in an attrl structure, defined in `pbs_ifl.h` as:

```
struct attrl {
        char *name;
        char *resource;
        char *value;
        struct attrl *next;
};
```

extend

Character string where you can specify limits or extensions of your selection.

24.25.3.1 Members of attropl Structure

next

Points to next attribute in list. A null pointer terminates the list.

name

Points to a string containing the name of the attribute.

resource

Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

value

Points to a string containing the value of the attribute or resource. For parameterized limit attributes, this string contains all parameters for the attribute.

op

Specifies the test to be applied to the attribute or resource. The operators are EQ, NE, GE, GT, LE, LT.

24.25.3.2 Members of attrl Structure

name

Points to a string containing the name of the attribute.

resource

Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

value

Points to a string containing the value of the attribute or resource. Should always be null.

next

Points to next attribute in list. A null pointer terminates the list.

24.25.4 Querying States

You can select jobs in more than one state using a single request, by listing all states you want returned. For example, to get jobs in *Held* and *Waiting* states:

- Fill in criteria_list->name with "*job_state*"
- Fill in criteria_list->value with "*HW*" for *Held* and *Waiting*

24.25.5 Extending Your Query

You can use the following characters in the extend parameter:

T, t

Extends query to include subjobs. Job arrays are not included.

x

Extends query to include finished and moved jobs.

24.25.5.1 Querying Finished and Moved Jobs

To get information on finished or moved jobs, as well as current jobs, add an '*x*' character to the extend parameter (set one character to be the '*x*' character). For example:

```
pbs_selstat ( ..., ..., <extend characters>) ...
```

To get information on finished jobs only:

- Add the '*x* character to the extend parameter
- Fill in criteria_list->name with "*ATTR_state*"
- Fill in criteria_list->value with "*FM*" for *Finished* and *Moved*

For example:

```
criteria_list->name = ATTR_state;
criteria_list->value = "FM";
criteria_list->op = EQ;
pbs_selstat ( ..., criteria_list, ..., extend) ...
```

Subjobs are not considered finished until the parent array job is finished.

24.25.5.2 Querying Job Arrays and Subjobs

To query only job arrays (not jobs or subjobs):

- Fill in criteria_list->name with "*array*"
- Fill in criteria_list->value with "*True*"

To query only job arrays and subjobs (not jobs):

- Fill in criteria_list->name with "*array*"
- Fill in criteria_list->value with "*True*"
- Add the '*T*' or '*t*' character to the extend parameter

To query only jobs and subjobs (not job arrays), add the '*T*' or '*t*' character to the extend parameter.

24.25.6 Return Value

Returns a pointer to a list of batch_status structures for jobs that meet the selection criteria. If no jobs meet the criteria or can be queried for status, returns the null pointer.

If an error occurred, the routine returns a null pointer, and the error number is available in the global integer pbs_errno.

24.25.6.1 The batch_status Structure

The batch_status structure is defined in pbs_ifl.h as

```
struct batch_status {
    struct batch_status *next;
    char *name;
    struct attrl *attribs;
    char *text;
}
```

24.25.7 Cleanup

You must free the list of batch_status structures when no longer needed, by calling `pbs_statfree()`.

qsig, qstat, pbs_connect, pbs_selectjob, pbs_statfree, pbs_statjob

24.26 pbs_sigjob

send a signal to a PBS batch job

24.26.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_sigjob(int connect, char *jobID, char *signal, char *extend)*

24.26.2 Description

Issues a batch request to send a signal to a batch job.

Generates a *Signal Job* (18) batch request and sends it to the server over the connection specified by connect.

You can send a signal to a job, job array, subjob, or range of subjobs.

The batch server sends the job the specified signal.

The job must be in the running or suspended state.

24.26.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

jobID

ID of job to be signaled.

Format for a job:

<sequence number>.<server name>

Format for a job array:

<sequence number>[].<server name>

Format for a subjob:

<sequence number>[<index>].<server name>

Format for a range of subjobs:

<sequence number>[<index start>-<index end>].<server name>

signal

Name of signal to send to job. Can be alphabetic, with or without SIG prefix. Can be signal number.

The following special signals are all lower-case, and have no associated signal number:

admin-suspend

Suspends a job and puts its vnodes into the *maintenance* state. The job is put into the *S* state and its processes are suspended.

admin-resume

Resumes a job that was suspended using the *admin-suspend* signal, without waiting for scheduler. Cannot be used on jobs that were suspended with the *suspend* signal. When the last admin-suspended job has been admin-resumed, the vnode leaves the maintenance state.

suspend

Suspends specified job(s). Job goes into *suspended (S)* state.

resume
Marks specified job(s) for resumption by scheduler when there are sufficient resources. Cannot be used on jobs that were suspended with the *admin_suspend* signal.

If the signal is not recognized on the execution host, no signal is sent and an error is returned.

extend
Character string for extensions to command. Not currently used.

24.26.4 Return Value

The routine returns *0* (*zero*) on success.

If an error occurred, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

24.26.5 See Also

qsig, pbs_connect

24.27 pbs_statfree

free a PBS status object

24.27.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*void pbs_statfree(struct batch_status *psj)*

24.27.2 Description

Frees the specified PBS status object returned by PBS API routines such as `pbs_statque()`, `pbs_statserver()`, `pbs_stathook()`, etc.

24.27.3 Arguments

psj

Pointer to the batch_status structure to be freed.

24.27.3.1 The batch_status Structure

The batch_status structure is defined in `pbs_ifl.h` as

```
struct batch_status {
    struct batch_status *next;
    char *name;
    struct attrl *attribs;
    char *text;
}
```

24.27.4 Return Value

No return value.

24.28 pbs_stathost

get status of PBS execution host(s)

24.28.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*void pbs_statfree(struct batch_status *psj)*

*struct batch_status *pbs_stathost(int connect, char *target, struct attrl *output_attribs, char *extend)*

24.28.2 Description

Issues a batch request to get the status of PBS execution hosts.

Generates a *Status Node* (58) batch request and sends it to the server over the connection specified by connect.

Returns specified attributes or all attributes of specified execution host or all execution hosts. If an execution host has multiple vnodes, this command reports aggregated information from the vnodes for that host.

24.28.3 Arguments

connect
: Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

target
: Name of execution host whose attributes are to be reported. If this argument is a null pointer or points to a null string, returns attributes of all execution hosts known to the server.

output_attribs
: Pointer to a list of attributes to return. If this argument is null, returns all attributes. Each attribute is described in an attrl structure, defined in `pbs_ifl.h` as:

```
struct attrl {
        char *name;
        char *resource;
        char *value;
        struct attrl *next;
};
```

extend
: Character string for extensions to command. Not currently used.

24.28.3.1 Members of attrl Structure

name
: Points to a string containing the name of the attribute.

resource
: Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

value
: Points to a string containing the value of the attribute or resource.

next
: Points to next attribute in list. A null pointer terminates the list.

24.28.4 Return Value

Returns a pointer to a list of batch_status structures describing the execution host(s).

If an error occurred, the routine returns a null pointer, and the error number is available in the global integer pbs_errno.

24.28.4.1 The batch_status Structure

The batch_status structure is defined in pbs_ifl.h as

```
struct batch_status {
    struct batch_status *next;
    char *name;
    struct attrl *attribs;
    char *text;
}
```

24.28.5 Cleanup

You must free the list of batch_status structures when no longer needed, by calling pbs_statfree().

24.28.6 See Also

qstat, pbs_connect, pbs_statfree

24.29 pbs_statjob

get status of PBS batch jobs

24.29.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*void pbs_statfree(struct batch_status *psj)*

*struct batch_status *pbs_statjob(int connect, char *ID, struct attrl *output_attribs, char *extend)*

24.29.2 Description

Issues a batch request to get the status of a specified batch job, a list of batch jobs, or the batch jobs at a queue or server.

Generates a *Status Job* (19) batch request and sends it to the server over the connection specified by connect.

You can query status of jobs, job arrays, subjobs, and ranges of subjobs.

Queries all specified jobs that the user is authorized to query.

24.29.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

ID

Job ID, list of job IDs, queue, server, or null.

If *ID* is a null pointer or points to a null string, gets status of jobs at connected server.

Format for a job:

<sequence number>.<server name>

Format for a job array:

<sequence number>[].<server name>

Format for a subjob:

<sequence number>[<index>].<server name>

Format for a range of subjobs:

<sequence number>[<index start>-<index end>].<server name>

Format for a list of jobs: comma-separated list of job IDs in a single string. White space is ignored. No limit on length:

"<job ID>,<job ID>,<job ID>, ..."

Format for a queue:

<queue name>@<server name>

Format for a server:

<server name>

output_attribs

Pointer to a list of attributes to return. If this list is null, all attributes are returned. Each attribute is described in an attrl structure, defined in pbs_ifl.h as:

```
struct attrl {
        char *name;
        char *resource;
        char *value;
        struct attrl *next;
};
```

extend

Character string where you can specify limits or extensions of your search. Order of characters is not important.

24.29.3.1 Members of attrl Structure

name

Points to a string containing the name of the attribute.

resource

Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

value

Points to a string containing the value of the attribute or resource.

next

Points to next attribute in list. A null pointer terminates the list.

24.29.4 Querying Job Arrays and Subjobs

You can query status of job arrays and their subjobs, or just the parent job arrays only.

To query status of job arrays and their subjobs, include the job array IDs in the ID argument, and include the '*t*' character in the extend argument. The function returns the status of each parent job array followed by status of each subjob in that job array.

To query status of one or more parent job arrays only, but not their subjobs, include their job IDs in the ID argument, but do not include anything in the extend argument.

24.29.5 Querying the Jobs at a Queue or Server

To query status of all jobs at a queue, give the queue name in the ID argument.

To query status of all jobs at a server, give the server name in the ID argument. If you give a null ID argument, the function queries the default server.

24.29.6 Extending Your Query

You can use the following characters in the extend parameter:

T, t

Extends query to include subjobs. Job arrays are not included.

x

Extends query to include finished and moved jobs.

24.29.6.1 Querying Finished and Moved Jobs

To get status for finished or moved jobs, as well as current jobs, add an '*x*' character to the extend parameter (set one character to be the '*x*' character). For example:

```
pbs_statjob ( ..., ..., <extend characters>) ...
```

Subjobs are not considered finished until the parent array job is finished.

24.29.7 Return Values

For a single job, if the job can be queried, returns a pointer to a batch_status structure containing the status of the specified job. If the job cannot be queried, returns a NULL pointer, and pbs_errno is set to an error number indicating the reason the job could not be queried.

For a list of jobs, if any of the specified jobs can be queried, returns a pointer to a batch_status structure containing the status of all the queryable jobs. If none of the jobs can be queried, returns a NULL pointer, and pbs_errno is set to the error number that indicates the reason that the last job in the list could not be queried.

For a queue, if the queue exists, returns a pointer to a batch_status structure containing the status of all the queryable jobs in the queue. If the queue does not exist, returns a NULL pointer, and pbs_errno is set to *PBSE_UNKQUE* (*15018*). If the queue exists but contains no queryable jobs, returns a NULL pointer, and pbs_errno is set to *PBSE_NONE* (*0*).

When querying a server, the connection to the server is already established by `pbs_connect()`. If there are jobs at the server, returns a pointer to a batch_status structure containing the status of all the queryable jobs at the server. If the server does not contain any queryable jobs, returns a NULL pointer, and pbs_errno is set to *PBSE_NONE* (*0*).

24.29.7.1 The batch_status Structure

The batch_status structure is defined in `pbs_ifl.h` as

```
struct batch_status {
    struct batch_status *next;
    char *name;
    struct attrl *attribs;
    char *text;
}
```

24.29.8 Cleanup

You must free the list of batch_status structures when no longer needed, by calling `pbs_statfree()`.

24.29.9 See Also

qstat, pbs_connect

24.30 pbs_statnode

get status of PBS execution host(s)

24.30.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*void pbs_statfree(struct batch_status *psj)*

*struct batch_status *pbs_statnode(int connect, char *target, struct attrl *output_attribs, char *extend)*

24.30.2 Description

Issues a batch request to get the status of PBS execution hosts.

Generates a *Status Node* (58) batch request and sends it to the server over the connection specified by connect.

Returns specified attributes or all attributes of specified execution host or all execution hosts. If an execution host has multiple vnodes, this command reports aggregated information from the vnodes for that host.

Identical to `pbs_stathost()`; retained for backward compatibility.

24.30.3 Arguments

connect
: Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

target
: Name of execution host whose attributes are to be reported. If this argument is null, returns attributes of all execution hosts known to the server.

output_attribs
: Pointer to a list of attributes to return. If this argument is a null pointer or points to a null string, returns all attributes. Each attribute is described in an attrl structure, defined in `pbs_ifl.h` as:

```
struct attrl {
        char *name;
        char *resource;
        char *value;
        struct attrl *next;
};
```

extend
: Character string for extensions to command. Not currently used.

24.30.3.1 Members of attrl Structure

name
: Points to a string containing the name of the attribute.

resource
: Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

value
: Points to a string containing the value of the attribute or resource.

next
: Points to next attribute in list. A null pointer terminates the list.

24.30.4 Return Value

Returns a pointer to a list of batch_status structures describing the host(s).

If an error occurred, the routine returns a null pointer, and the error number is available in the global integer pbs_errno.

24.30.4.1 The batch_status Structure

The batch_status structure is defined in pbs_ifl.h as

```
struct batch_status {
    struct batch_status *next;
    char *name;
    struct attrl *attribs;
    char *text;
}
```

24.30.5 Cleanup

You must free the list of batch_status structures when no longer needed, by calling pbs_statfree().

24.30.6 See Also

qstat, pbs_connect

24.31 pbs_statque

get status of PBS queue(s)

24.31.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*struct batch_status *pbs_statque(int connect, char *target, struct attrl *output_attribs, char *extend)*

24.31.2 Description

Issues a batch request to get the status of PBS queues.

Generates a *Status Queue* (20) batch request and sends it to the server over the connection specified by connect.

Returns specified attributes or all attributes of specified queue or all queues.

24.31.3 Arguments

connect
: Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

target
: Name of queue whose attributes are to be reported. If this argument is null, returns attributes of all queues known to the server.

output_attribs
: Pointer to a list of attributes to return. If this argument is a null pointer or points to a null string, returns all attributes. Each attribute is described in an attrl structure, defined in `pbs_ifl.h` as:

```
struct attrl {
        char *name;
        char *resource;
        char *value;
        struct attrl *next;
};
```

extend
: Character string for extensions to command. Not currently used.

24.31.3.1 Members of attrl Structure

name
: Points to a string containing the name of the attribute.

resource
: Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

value
: Points to a string containing the value of the attribute or resource.

next

Points to next attribute in list. A null pointer terminates the list.

24.31.4 Return Value

Returns a pointer to a list of batch_status structures describing the queue(s).

If an error occurred, the routine returns a null pointer, and the error number is available in the global integer pbs_errno.

24.31.4.1 The batch_status Structure

The batch_status structure is defined in pbs_ifl.h as

```
struct batch_status {
    struct batch_status *next;
    char *name;
    struct attrl *attribs;
    char *text;
}
```

24.31.5 Cleanup

You must free the list of batch_status structures when no longer needed, by calling pbs_statfree().

24.31.6 See Also

qstat, pbs_connect, pbs_statfree

24.32 pbs_statresv

get status of PBS reservation(s)

24.32.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*void pbs_statfree(struct batch_status *psj)*

*struct batch_status *pbs_statresv(int connect, char *target, struct attrl *output_attribs, char *extend)*

24.32.2 Description

Issues a batch request to get the status of PBS reservation(s).

Generates a *Status Reservation* (71) batch request and sends it to the server over the connection specified by connect.

Returns specified attributes or all attributes of specified reservation or all reservations.

24.32.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

target

ID of reservation whose attributes are to be reported. If this argument is a null pointer or points to a null string, returns attributes of all reservations the user is authorized to query.

Format for advance reservation:

R<sequence number>.<server name>

Format for standing reservation:

S<sequence number>.<server name>

Format for maintenance reservation:

M<sequence number>.<server name>

output_attribs

Pointer to a list of attributes to return. If this argument is null, returns all attributes. Each attribute is described in an attrl structure, defined in `pbs_ifl.h` as:

```
struct attrl {
        char *name;
        char *resource;
        char *value;
        struct attrl *next;
};
```

extend

Character string for extensions to command. Not currently used.

24.32.3.1 Members of attrl Structure

name
: Points to a string containing the name of the attribute.

resource
: Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

value
: Points to a string containing the value of the attribute or resource.

next
: Points to next attribute in list. A null pointer terminates the list.

24.32.4 Return Value

Returns a pointer to a list of batch_status structures describing the reservation(s).

If an error occurred, the routine returns a null pointer, and the error number is available in the global integer pbs_errno.

24.32.4.1 The batch_status Structure

The batch_status structure is defined in pbs_ifl.h as

```
struct batch_status {
    struct batch_status *next;
    char *name;
    struct attrl *attribs;
    char *text;
}
```

24.32.5 Cleanup

You must free the list of batch_status structures when no longer needed, by calling pbs_statfree().

24.32.6 See Also

qstat, pbs_connect, pbs_statfree

24.33 pbs_statrsc

get status of PBS resources

24.33.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*void pbs_statfree(struct batch_status *psj)*

*struct batch_status *pbs_statrsc(int connect, char *rescname, struct attrl *output_attribs, char *extend)*

24.33.2 Description

Issues a batch request to query and return the status of a specified resource, or a set of resources at a server.

Generates a *Status Resource* (82) batch request and sends it to the server over the connection specified by connect.

24.33.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

rescname

Name of resource to be queried. If this is null, queries all resources at the server.

output_attribs

Pointer to a list of attributes to return. If this argument is a null pointer or points to a null string, returns all attributes. Each attribute is described in an attrl structure, defined in `pbs_ifl.h` as:

```
struct attrl {
        char *name;
        char *resource;
        char *value;
        struct attrl *next;
};
```

extend

Character string for extensions to command. Not currently used.

24.33.3.1 Members of attrl Structure

name

Points to a string containing the name of the attribute.

resource

Points to a string containing the name of a resource. Should be a null pointer.

value

Points to a string containing the value of the attribute or resource. Should always be a pointer to a null string.

next

Points to next attribute in list. A null pointer terminates the list.

24.33.4 Querying Resources at Server

Use the pbs_connect() command to get a connection handle at the server.

To query all resources at the server, pass a null pointer as the name of the resource.

24.33.5 Return Value

For a single resource, if the resource can be queried, returns a pointer to a batch_status structure containing the status of the specified resource.

If the resource cannot be queried, the routine returns a null pointer, and the error number is available in the global integer pbs_errno.

When querying a server, the connection to the server is already established by pbs_connect(). If there are resources at the server, returns a pointer to a batch_status structure describing the queryable resource(s) at the server.

In the unlikely event that the server does not contain any queryable resources because the user is unprivileged and all resources are marked as invisible (the i flag is set), returns a NULL pointer, and pbs_errno is set to *PBSE_NONE* (*0*).

24.33.5.1 The batch_status Structure

The batch_status structure is defined in pbs_ifl.h as

```
struct batch_status {
    struct batch_status *next;
    char *name;
    struct attrl *attribs;
    char *text;
}
```

24.33.6 Cleanup

You must free the list of batch_status structures when no longer needed, by calling pbs_statfree().

24.33.7 See Also

qstat, pbs_connect

24.34 pbs_statsched

get status of PBS schedulers

24.34.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*void pbs_statfree(struct batch_status *psj)*

*struct batch_status *pbs_statsched(int connect, struct attrl *output_attribs, char *extend)*

24.34.2 Description

Issues a batch request to get the status of the PBS schedulers.

Generates a *Status Scheduler (81)* batch request and sends it to the server over the connection specified by connect.

This command returns status of the default scheduler and all multischeds.

24.34.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

output_attribs

Pointer to a list of attributes to return. If this argument is a null pointer or points to a null string, returns all attributes. Each attribute is described in an attrl structure, defined in `pbs_ifl.h` as:

```
struct attrl {
        char *name;
        char *resource;
        char *value;
        struct attrl *next;
};
```

extend

Character string for extensions to command. Not currently used.

24.34.3.1 Members of attrl Structure

name

Points to a string containing the name of the attribute.

resource

Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

value

Points to a string containing the value of the attribute or resource. Should always be a pointer to a null string.

next

Points to next attribute in list. A null pointer terminates the list.

24.34.4 Return Value

Returns a pointer to a list of batch_status structures describing the default scheduler and all multischeds.

If an error occurred, the routine returns a null pointer, and the error number is available in the global integer pbs_errno.

24.34.4.1 The batch_status Structure

The batch_status structure is defined in pbs_ifl.h as

```
struct batch_status {
    struct batch_status *next;
    char *name;
    struct attrl *attribs;
    char *text;
}
```

24.34.5 Cleanup

You must free the list of batch_status structures when no longer needed, by calling pbs_statfree().

24.34.6 See Also

qstat, pbs_connect

24.35 pbs_statserver

get status of a PBS batch server

24.35.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*void pbs_statfree(struct batch_status *psj)*

*struct batch_status *pbs_statserver(int connect, struct attrl *output_attribs, char *extend)*

24.35.2 Description

Issues a batch request to get the status of a batch server.

Generates a *Status Server* (21) batch request and sends it to the server over the connection specified by connect.

24.35.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

output_attribs

Pointer to a list of attributes to return. If this argument is a null pointer or points to a null string, returns all attributes. Each attribute is described in an attrl structure, defined in `pbs_ifl.h` as:

```
struct attrl {
        char *name;
        char *resource;
        char *value;
        struct attrl *next;
};
```

extend

Character string for extensions to command. Not currently used.

24.35.3.1 Members of attrl Structure

name

Points to a string containing the name of the attribute.

resource

Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

value

Points to a string containing the value of the attribute or resource. Should always be a pointer to a null string.

next

Points to next attribute in list. A null pointer terminates the list.

24.35.4 Return Value

Returns a pointer to a batch_status structure describing the server.

If an error occurred, the routine returns a null pointer, and the error number is available in the global integer pbs_errno.

24.35.4.1 The batch_status Structure

The batch_status structure is defined in pbs_ifl.h as

```
struct batch_status {
    struct batch_status *next;
    char *name;
    struct attrl *attribs;
    char *text;
}
```

24.35.5 Cleanup

You must free the batch_status structure when no longer needed, by calling pbs_statfree().

24.36 pbs_statvnode

get status of PBS vnode(s) on execution hosts

24.36.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*void pbs_statfree(struct batch_status *psj)*

*struct batch_status *pbs_statvnode(int connect, char *target, struct attrl *output_attribs, char *extend)*

24.36.2 Description

Issues a batch request to get the status of PBS vnodes on execution hosts.

Generates a *Status Node* (58) batch request and sends it to the server over the connection specified by connect.

Returns specified attributes or all attributes of specified execution host vnode or all execution host vnodes.

24.36.3 Arguments

connect
: Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

target
: Name of execution host vnode whose attributes are to be reported. If this argument is null, returns attributes of all execution host vnodes known to the server.

output_attribs
: Pointer to a list of attributes to return. If this argument is a null pointer or points to a null string, returns all attributes. Each attribute is described in an attrl structure, defined in `pbs_ifl.h` as:

```
struct attrl {
        char *name;
        char *resource;
        char *value;
        struct attrl *next;
};
```

extend
: Character string for extensions to command. Not currently used.

24.36.3.1 Members of attrl Structure

name
: Points to a string containing the name of the attribute.

resource
: Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

value
: Points to a string containing the value of the attribute or resource.

next
: Points to next attribute in list. A null pointer terminates the list.

24.36.4 Return Value

Returns a pointer to a list of batch_status structures describing the vnode(s).

If an error occurred, the routine returns a null pointer, and the error number is available in the global integer pbs_errno.

24.36.4.1 The batch_status Structure

The batch_status structure is defined in pbs_ifl.h as

```
struct batch_status {
    struct batch_status *next;
    char                *name;
    struct attrl        *attribs;
    char                *text;
}
```

24.36.5 Cleanup

You must free the list of batch_status structures when no longer needed, by calling pbs_statfree().

24.36.6 See Also

qstat, pbs_connect, pbs_statfree

24.37 pbs_submit

submit a PBS batch job

24.37.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*char *pbs_submit(int connect, struct attropl *attrib_list, char *jobscript, char *destqueue, char *extend)*

24.37.2 Description

Issues a batch request to submit a new batch job.

Generates a *Queue Job* (1) batch request and sends it to the server over the connection specified by connect.

Submits job to specified queue at connected server, or if no queue is specified, to default queue at connected server.

24.37.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

attrib_list

Pointer to a list of attributes explicitly requested for job. Each attribute is described in an attropl structure, defined in `pbs_ifl.h` as:

```
struct attropl {
        struct attropl *next;
        char *name;
        char *resource;
        char *value;
        enum batch_op op;
};
```

For any attribute that is not specified or that is a null pointer, PBS takes the default action for that attribute. The default action is to assign the default value or to not pass the attribute with the job; the action depends on the attribute.

jobscript

Pointer to path to job script. Can be absolute or relative. Relative path begins with the directory where the user submits the job.

If null pointer or pointer to null string, no script is passed with job.

destqueue

Pointer to name of destination queue at connected server. If this is a null pointer or points to a null string, the job is submitted to the default queue at the connected server.

extend

Character string for extensions to command. Not currently used.

24.37.3.1 Members of attropl Structure

next
: Points to next attribute in list. A null pointer terminates the list.

name
: Points to a string containing the name of the attribute.

resource
: Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

value
: Points to a string containing the value of the attribute or resource.

op
: Operation to perform on the attribute or resource. In this command, the only allowed operator is SET.

24.37.4 Return Value

Returns a pointer to a character string containing the job ID assigned by the server.

If an error occurred, the routine returns a null pointer, and the error number is available in the global integer pbs_errno.

24.37.5 Cleanup

The space for the job ID returned by `pbs_submit()` is allocated by `pbs_submit()`. Free it via a call to `free()` when you no longer need it.

qsub, pbs_connect

24.38 pbs_submit_resv

submit a PBS reservation

24.38.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*char *pbs_submit_resv(int connect, struct attropl *attrib_list, char *extend)*

24.38.2 Description

Issues a batch request to submit a new reservation.

Generates a *Submit Reservation* (70) batch request and sends it to the server over the connection specified by connect.

Returns a pointer to the reservation ID.

24.38.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection over which to send batch request to server.

attrib_list

Pointer to a list of attributes to set, with values. Each attribute is described in an attropl structure, defined in `pbs_ifl.h` as:

```
struct attropl {
        struct attropl *next;
        char *name;
        char *resource;
        char *value;
        enum batch_op op;
};
```

For any attribute that is not specified or that is a null pointer, PBS takes the default action for that attribute. The default action is to assign the default value or to not pass the attribute with the reservation; the action depends on the attribute.

extend

Character string for extensions to command. Not currently used.

24.38.3.1 Members of attropl Structure

next

Points to next attribute in list. A null pointer terminates the list.

name

Points to a string containing the name of the attribute.

resource

Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

value

Points to a string containing the value of the attribute or resource.

op

Operator. The only allowed operator for this function is SET.

24.38.4 Return Value

Returns a pointer to a character string containing the reservation ID assigned by the server.

If an error occurred, the routine returns a null pointer, and the error number is available in the global integer pbs_errno.

24.38.5 Cleanup

The space for the reservation ID returned by `pbs_submit_resv()` is allocated by `pbs_submit_resv()`. Free it via a call to `free()` when you no longer need it.

24.39 pbs_terminate

shut down a PBS batch server

24.39.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*int pbs_terminate(int connect, int manner, char *extend)*

24.39.2 Description

Issues a batch request to shut down a batch server.

Generates a *Server Shutdown* (17) batch request and sends it to the server over the connection specified by connect.

The `pbs_terminate()` command exits after the server has completed its shutdown procedure.

24.39.3 Required Privilege

You must have Operator or Manager privilege to run this command.

24.39.4 Arguments

connect
: Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

manner
: Manner in which to shut down server. The available manners are defined in `pbs_ifl.h`. Valid values: *SHUT_IMMEDIATE, SHUT_DELAY, SHUT_QUICK*. See "qterm" on page 236 of the PBS Professional Reference Guide for information on manner in which to shut down server.

extend
: Character string for extensions to command. Not currently used.

24.39.5 Return Value

The routine returns *0* (*zero*) on success.

If an error occurred, the routine returns a non-zero exit value, and the error number is available in the global integer pbs_errno.

TM Library

This chapter describes the PBS Task Management library. The TM library is a set of routines used to manage multi-process, parallel, and distributed applications.

25.1 TM Library Routines

The following manual pages document the application programming interface provided by the TM library.

25.2 tm_init, tm_nodeinfo, tm_poll, tm_notify, tm_spawn, tm_kill, tm_obit, tm_taskinfo, tm_atnode, tm_rescinfo, tm_publish, tm_subscribe, tm_finalize, tm_attach

task management API

25.2.1 Synopsis

```
#include <tm.h>
int tm_init(info, roots)
    void *info;
    struct tm_roots *roots;
    int tm_nodeinfo(list, nnodes)
tm_node_id **list;
    int *nnodes;
int tm_poll(poll_event, result_event, wait, tm_errno)
    tm_event_t poll_event;
    tm_event_t *result_event;
    int wait;
    int *tm_errno;
int tm_notify(tm_signal)
    int tm_signal;
int tm_spawn(argc, argv, envp, where, tid, event)
    int argc;
    char **argv;
    char **envp;
    tm_node_id where;
    tm_task_id *tid;
    tm_event_t *event;
int tm_kill(tid, sig, event)
    tm_task_id tid;
    int sig;
    tm_event_t *event;
int tm_obit(tid, obitval, event)
    tm_task_id tid;
    int *obitval;
    tm_event_t *event;
int tm_taskinfo(node, tid_list, list_size, ntasks, event)
    tm_node_id node;
    tm_task_id *tid_list;
    int list_size;
    int *ntasks;
    tm_event_t *event;
int tm_atnode(tid, node)
    tm_task_id tid;
    tm_node_id *node;
int tm_rescinfo(node, resource, len, event)
    tm_node_id node;
    char *resource;
    int len;
    tm_event_t *event;
int tm_publish(name, info, len, event)
```

```
        char *name;
        void *info;
        int len;
        tm_event_t *event;
    int tm_subscribe(tid, name, info, len, info_len, event)
        tm_task_id tid;
        char *name;
        void *info;
        int len;
        int *info_len;
        tm_event_t *event;
    int tm_attach(jobid, cookie, pid, tid, host, port)
        char *jobid;
        char *cookie;
        pid_t pid;
        tm_task_id *tid;
        char *host;
        int port;
    int tm_finalize()
```

25.2.2 Description

These functions provide a partial implementation of the task management interface part of the PSCHED API. In PBS, MoM provides the task manager functions. This library opens a tcp socket to the MoM running on the local host and sends and receives messages using the DIS protocol (described in the PBS IDS). The tm interface can only be used by a process within a PBS job.

The PSCHED Task Management API description used to create this library was committed to paper on November 15, 1996 and was given the version number 0.1. Changes may have taken place since that time which are not reflected in this library.

The API description uses several data types that it purposefully does not define. This was done so an implementation would not be confined in the way it was written. For this specific work, the definitions follow:

typedef int tm_node_id; /* job-relative node id */

#define TM_ERROR_NODE ((tm_node_id)-1)

typedef int tm_event_t; /* > 0 for real events */

#define TM_NULL_EVENT ((tm_event_t)0)

#define TM_ERROR_EVENT ((tm_event_t)-1)

typedef unsigned long tm_task_id;

#define TM_NULL_TASK (tm_task_id)0

There are a number of error values defined as well: TM_SUCCESS, TM_ESYSTEM, TM_ENOEVENT, TM_ENOTCONNECTED, TM_EUNKNOWNCMD, TM_ENOTIMPLEMENTED, TM_EBADENVIRONMENT, TM_ENOTFOUND.

tm_init() initializes the library by opening a socket to the MoM on the local host and sending a TM_INIT message, then waiting for the reply. The info parameter has no use and is included to conform with the PSCHED document. The roots pointer will contain valid data after the function returns and has the following structure:

struct tm_roots {

tm_task_id tm_me;

tm_task_id tm_parent;

int tm_nnodes;

int tm_ntasks;

int tm_taskpoolid;

tm_task_id *tm_tasklist;

};

tm_me The task id of this calling task.

tm_parent The task id of the task which spawned this task or TM_NULL_TASK if the calling task is the initial

task started by PBS.

tm_nnodes The number of nodes allocated to the job.

tm_ntasks This will always be 0 for PBS.

tm_taskpoolid PBS does not support task pools so this will always be -1.

tm_tasklist This will be NULL for PBS.

The tm_ntasks, tm_taskpoolid and tm_tasklist fields are not filled with data specified by the PSCHED document. PBS does not support task pools and, at this time, does not return information about current running tasks from tm_init. There is a separate call to get information for current running tasks called tm_taskinfo which is described below. The return value from tm_init is TM_SUCCESS if the library initialization was successful, or an error is returned otherwise.

tm_nodeinfo() places a pointer to a malloc'ed array of tm_node_id's in the pointer pointed at by list. The order of the tm_node_id's in list is the same as that specified to MoM in the "exec_host" attribute. The int pointed to by nnodes contains the number of nodes allocated to the job. This is information that is returned during initialization and does not require communication with MoM. If tm_init has not been called, TM_ESYSTEM is returned, otherwise TM_SUCCESS is returned.

tm_poll() is the function which will retrieve information about the task management system to locations specified when other routines request an action take place. The bookkeeping for this is done by generating an event for each action. When the task manager (MoM) sends a message that an action is complete, the event is reported by tm_poll and information is placed where the caller requested it. The argument poll_event is meant to be used to request a specific event. This implementation does not use it and it must be set to TM_NULL_EVENT or an error is returned. Upon return, the argument result_event will contain a valid event number or TM_ERROR_EVENT on error. If wait is zero and there are no events to report, result_event is set to TM_NULL_EVENT. If wait is non-zero an there are no events to report, the function will block waiting for an event. If no local error takes place, TM_SUCCESS is returned. If an error is reported by MoM for an event, then the argument tm_errno will be set to an error code.

tm_notify() is described in the PSCHED documentation, but is not implemented for PBS yet. It will return TM_ENOTIMPLEMENTED.

tm_spawn() sends a message to MoM to start a new task. The node id of the host to run the task is given by where. The parameters argc, argv and envp specify the program to run and its arguments and environment very much like exec(). The full path of the program executable must be given by argv[0] and the number of elements in the argv array is given by argc. The array envp is NULL terminated. The argument event points to a tm_event_t variable which is filled in with an event number. When this event is returned by tm_poll, the tm_task_id pointed to by tid will contain the task id of the newly created task.

tm_kill() sends a signal specified by sig to the task tid and puts an event number in the tm_event_t pointed to by event.

tm_obit() creates an event which will be reported when the task tid exits. The int pointed to by obitval will contain the exit value of the task when the event is reported.

tm_taskinfo() returns the list of tasks running on the node specified by node. The PSCHED documentation mentions a special ability to retrieve all tasks running in the job. This is not supported by PBS. The argument tid_list points to an array of tm_task_id's which contains list_size elements. Upon return, event will contain an event number. When this event is polled, the int pointed to by ntasks will contain the number of tasks running on the node and the array will be filled in with tm_task_id's. If ntasks is greater than list_size, only list_size tasks will be returned.

tm_atnode() will place the node id where the task tid exists in the tm_node_id pointed to by node.

tm_rescinfo() makes a request for a string specifying the resources available on a node given by the argument node. The string is returned in the buffer pointed to by resource and is terminated by a NUL character unless the number of characters of information is greater than specified by len. The resource string PBS returns is formatted as follows:

A space separated set of strings from the uname system call. The order of the strings is sysname, nodename, release, version, machine.

A comma separated set of strings giving the components of the "Resource_List" attribute of the job, preceded by a colon (:). Each component has the resource name, an equal sign, and the limit value.

tm_publish() causes len bytes of information pointed at by info to be sent to the local MoM to be saved under the name given by name.

tm_subscribe() returns a copy of the information named by name for the task given by tid. The argument info points to a buffer of size len where the information will be returned. The argument info_len will be set with the size of the published data. If this is larger than the supplied buffer, the data will have been truncated.

tm_attach() commands MoM to create a new PBS "attached task" out of a session running on MoM's host. The jobid parameter specifies the job which is to have a new task attached. If it is NULL, the system will try to determine the correct jobid. The cookie parameter must be NULL. The pid parameter must be a non-zero process id for the process which is to be added to the job specified by jobid. If tid is non-NULL, it will be used to store the task id of the new task. The host and port parameters specify where to contact MoM. host should be NULL. The return value will be 0 if a new task has been successfully created and non-zero on error. The return value will be one of the TM error numbers defined in tm.h as follows:

TM_ESYSTEM MoM cannot be contacted

TM_ENOTFOUND No matching job was found

TM_ENOTIMPLEMENTED The call is not implemented/supported

TM_ESESSION The session specified is already attached

TM_EUSER The calling user is not permitted to attach

TM_EOWNER The process owner does not match the job

TM_ENOPROC The process does not exist

tm_finalize() may be called to free any memory in use by the library and close the connection to MoM.

26
RM Library

This chapter describes the PBS Resource Monitor library. The RM library contains functions to facilitate communication with the PBS Professional resource monitor. It is set up to make it easy to connect to several resource monitors and handle the network communication efficiently.

26.1 RM Library Routines

The following manual pages document the application programming interface provided by the RM library.

26.2 openrm, closerm, downrm, configrm, addreq, allreq, getreq, flushreq, activereq, fullresp

resource monitor API

26.2.1 Synopsis

```
#include <sys/types.h>
#include <netinet/in.h>
#include <rm.h>
int openrm (host, port)
    char *host;
    unsigned int port;
int closerm (stream)
    int stream;
int downrm (stream)
    int stream;
int configrm (stream, file)
    int stream;
    char *file;
int addreq (stream, line)
    int stream;
    char *line;
int allreq (line)
    char *line;
char *getreq(stream)
    int stream;
int flushreq()
int activereq()
void fullresp(flag)
    int flag;
```

26.2.2 Description

The resource monitor library contains functions to facilitate communication with the PBS Professional resource monitor. It is set up to make it easy to connect to several resource monitors and handle the network communication efficiently.

In all these routines, the variable pbs_errno will be set when an error is indicated. The lower levels of network protocol are handled by the "Data Is Strings" DIS library and the TPP library.

configrm() causes the resource monitor to read the file named. Deprecated.

addreq() begins a new message to the resource monitor if necessary. Then adds a line to the body of an outstanding command to the resource monitor.

allreq() begins, for each stream, a new message to the resource monitor if necessary. Then adds a line to the body of an outstanding command to the resource monitor.

getreq() finishes and sends any outstanding message to the resource monitor. If fullresp() has been called to turn off "full response" mode, the routine searches down the line to find the equal sign just before the response value. The returned string (if it is not NULL) has been allocated by malloc and thus free must be called when it is no longer needed to prevent memory leaks.

flushreq() finishes and sends any outstanding messages to all resource monitors. For each active resource monitor structure, it checks if any outstanding data is waiting to be sent. If there is, it is sent and the internal structure is marked to show "waiting for response".

fullresp() turns on, if flag is true, "full response" mode where getreq() returns a pointer to the beginning of a line of response. This is the default. If flag is false, the line returned by getreq() is just the answer following the equal sign.

activereq() Returns the stream number of the next stream with something to read or a negative number (the return from tpp_poll) if there is no stream to read.

In order to use any of the above with Windows, initialize the network library and link with winsock2. To do this, call winsock_init() before calling the function and link against the ws2_32.lib library.

27
TCL/tk Interface

As of version 19.4.1, the PBS TCL API is **deprecated**.

The PBS Professional software includes a TCL/tk interface to PBS. Wrapped versions of many of the API calls are compiled into a special version of the TCL shell, called `pbs_tclsh`. (A special version of the tk window shell is also provided, called `pbs_wish`.). This chapter documents the TCL/tk interface to PBS.

The `pbs_tclapi` is a subset of the PBS external API wrapped in a TCL library. This functionality allows the creation of scripts that query the PBS system. Specifically, it permits the user to query the `pbs_server` about the state of PBS, jobs, queues, and nodes, and communicate with `pbs_mom` to get information about the status of running jobs, available resources on nodes, etc.

27.1 TCL/tk API Functions

A set of functions to communicate with the PBS server and resource monitor have been added to those normally available with Tcl. All these calls will set the Tcl variable pbs_errno to a value to indicate if an error occurred. In all cases, the value "*0*" means no error. If a call to a Resource Monitor function is made, any error value will come from the system supplied errno variable. If the function call communicates with the PBS server, any error value will come from the error number returned by the server. This is the same TCL interface used by the `pbs_tclsh` and `pbs_wish` commands.

Note that the `pbs_tclapi pbsrescquery` command, which calls the C API `pbs_rescquery`, is **obsolete**. Any attempt to use it will result in a PBSE_NOSUPPORT error being returned.

27.2 pbs_tclapi

PBS TCL Application Programming Interface

27.2.1 Description

The pbs_tclapi is a subset of the PBS external API wrapped in a TCL library. This functionality allows the creation of scripts that query the PBS system. Specifically, it permits the user to query the pbs_server about the state of PBS, jobs, queues, and nodes, and communicate with pbs_mom to get information about the status of running jobs, available resources on nodes, etc.

27.2.2 Usage

A set of functions to communicate with the PBS server and resource monitor have been added to those normally available with Tcl. All these calls will set the Tcl variable "pbs_errno" to a value to indicate if an error occurred. In all cases, the value "0" means no error. If a call to a Resource Monitor function is made, any error value will come from the system supplied errno variable. If the function call communicates with the PBS Server, any error value will come from the error number returned by the server. This is the same TCL interface used by the pbs_tclsh and pbs_wish commands.

openrm host ?port?

Creates a connection to the PBS Resource Monitor on host using port as the port number or the standard port for the resource monitor if it is not given. A connection handle is returned. If the open is successful, this will be a non-negative integer. If not, an error occurred.

closerm connection

The parameter connection is a handle to a resource monitor which was previously returned from openrm. This connection is closed.

Nothing is returned.

downrm connection

Sends a command to the connected resource monitor to shutdown.

Nothing is returned.

configrm connection filename

Sends a command to the connected resource monitor to read the configuration file given by filename. If this is successful, a "0" is returned, otherwise, "-1" is returned.

addreq connection request

A resource request is sent to the connected resource monitor. If this is successful, a "0" is returned, otherwise, "-1" is returned.

getreq connection

One resource request response from the connected resource monitor is returned. If an error occurred or there are no more responses, an empty string is returned.

allreq request

A resource request is sent to all connected resource monitors. The number of streams acted upon is returned.

flushreq

All resource requests previously sent to all connected resource monitors are flushed out to the network. Nothing is returned.

activereq

The connection number of the next stream with something to read is returned. If there is nothing to read from any of the connections, a negative number is returned.

fullresp flag

Evaluates flag as a boolean value and sets the response mode used by getreq to full if flag evaluates to "true". The full return from a resource monitor includes the original request followed by an equal sign followed by the response. The default situation is only to return the response following the equal sign. If a script needs to "see" the entire line, this function may be used.

pbsstatserv

The server is sent a status request for information about the server itself. If the request succeeds, a list with three elements is returned, otherwise an empty string is returned. The first element is the server's name. The second is a list of attributes. The third is the "text" associated with the server (usually blank).

pbsstatjob

The server is sent a status request for information about the all jobs resident within the server. If the request succeeds, a list is returned, otherwise an empty string is returned. The list contains an entry for each job. Each element is a list with three elements. The first is the job's jobid. The second is a list of attributes. The attribute names which specify resources will have a name of the form "Resource_List:name" where "name" is the resource name. The third is the "text" associated with the job (usually blank).

pbsstatque

The server is sent a status request for information about all queues resident within the server. If the request succeeds, a list is returned, otherwise an empty string is returned. The list contains an entry for each queue. Each element is a list with three elements. This first is the queue's name. The second is a list of attributes similar to pbsstatjob. The third is the "text" associated with the queue (usually blank).

pbsstatnode

The server is sent a status request for information about all nodes defined within the server. If the request succeeds, a list is returned, otherwise an empty string is returned. The list contains an entry for each node. Each element is a list with three elements. This first is the node's name. The second is a list of attributes similar to pbsstatjob. The third is the "text" associated with the node (usually blank).

pbsselstat

The server is sent a status request for information about the all runnable jobs resident within the server. If the request succeeds, a list similar to pbsstatjob is returned, otherwise an empty string is returned.

pbsrunjob jobid ?location?

Run the job given by jobid at the location given by location. If location is not given, the default location is used. If this is successful, a "0" is returned, otherwise, "-1" is returned.

pbsasyrunjob jobid ?location?

Run the job given by jobid at the location given by location without waiting for a positive response that the job has actually started. If location is not given, the default location is used. If this is successful, a "0" is returned, otherwise, "-1" is returned.

pbsrerunjob jobid

Re-runs the job given by jobid. If this is successful, a "0" is returned, otherwise, "-1" is returned.

pbsdeljob jobid

Delete the job given by jobid. If this is successful, a "0" is returned, otherwise, "-1" is returned.

pbsholdjob jobid

Place a hold on the job given by jobid. If this is successful, a "0" is returned, otherwise, "-1" is returned.

pbsmovejob jobid ?location?

Move the job given by jobid to the location given by location. If location is not given, the default location is used. If this is successful, a "0" is returned, otherwise, "-1" is returned.

pbsqenable queue

Set the "enabled" attribute for the queue given by queue to true. If this is successful, a "0" is returned, otherwise, "-1" is returned.

pbsqdisable queue

Set the "enabled" attribute for the queue given by queue to false. If this is successful, a "0" is returned, otherwise, "-1" is returned.

pbsqstart queue

Set the "started" attribute for the queue given by queue to true. If this is successful, a "0" is returned, otherwise, "-1" is

returned.

pbsqstop queue

Set the "started" attribute for the queue given by queue to false. If this is successful, a "0" is returned, otherwise, "-1" is returned.

pbsalterjob jobid attribute_list

Alter the attributes for a job specified by jobid. The parameter attribute_list is the list of attributes to be altered. There can be more than one. Each attribute consists of a list of three elements. The first is the name, the second the resource and the third is the new value. If the alter is successful, a "0" is returned, otherwise, "-1" is returned.

pbsrescquery resource_list

Deprecated. Obtain information about the resources specified by resource_list. This will be a list of strings. If the request succeeds, a list with the same number of elements as resource_list is returned. Each element in this list will be a list with four numbers. The numbers specify available, allocated, reserved, and down in that order.

pbsconnect ?server?

Make a connection to the named server or the default server if a parameter is not given. Only one connection to a server is allowed at any one time.

pbsdisconnect

Disconnect from the currently connected server.

The above Tcl functions use PBS interface library calls for communication with the server and the PBS resource monitor library to communicate with pbs_mom.

datetime ?day? ?time?

The number of arguments used determine the type of date to be calculated. With no arguments, the current POSIX date is returned. This is an integer in seconds.

With one argument there are two possible formats. The first is a 12 (or more) character string specifying a complete date in the following format:

YYMMDDhhmmss

All characters must be digits. The year (YY) is given by the first two (or more) characters and is the number of years since 1900. The month (MM) is the number of the month [01-12]. The day (DD) is the day of the month [01-32]. The hour (hh) is the hour of the day [00-23]. The minute (mm) is minutes after the hour [00-59]. The second (ss) is seconds after the minute [00-59]. The POSIX date for the given date/time is returned.

The second option with one argument is a relative time. The format for this is

HH:MM:SS

With hours (HH), minutes (MM) and seconds (SS) being separated by colons ":". The number returned in this case will be the number of seconds in the interval specified, not an absolute POSIX date.

With two arguments a relative date is calculated. The first argument specifies a day of the week and must be one of the following strings: "Sun", "Mon", "Tue", "Wed", "Thr", "Fri", or "Sat". The second argument is a relative time as given above. The POSIX date calculated will be the day of the week given which follows the current day, and the time given in the second argument. For example, if the current day was Monday, and the two arguments were "Fri" and "04:30:00", the date calculated would be the POSIX date for the Friday following the current Monday, at four-thirty in the morning. If the day specified and the current day are the same, the current day is used, not the day one week later.

strftime format time

This function calls the POSIX function strftime(). It requires two arguments. The first is a format string. The format conventions are the same as those for the POSIX function strftime(). The second argument is POSIX calendar time in second as returned by datetime. It returns a string based on the format given. This gives the ability to extract information about a time, or format it for printing.

logmsg tag message

This function calls the internal PBS function log_err(). It will cause a log message to be written to the scheduler's log file. The tag specifies a function name or other word used to identify the area where the message is generated. The message is the string to be logged.

28 Hooks

This chapter describes the PBS hook APIs. For more information on hooks, see the PBS Professional Administrator's Guide.

28.1 Introduction

A hook is a block of Python code that is triggered in response to queueing a job, modifying a job, moving a job, running a job, submitting a PBS reservation, MoM receiving a job, MoM starting a job, MoM killing a job, a job finishing, and MoM cleaning up a job. Each hook can *accept* (allow) or *reject* (prevent) the action that triggers it. The hook can modify the input parameters given for the action. The hook can also make calls to functions external to PBS. PBS provides an interface for use by hooks. This interface allows hooks to read and/or modify things such as job and server attributes, the server, queues, and the event that triggered the hook.

The Administrator creates any desired hooks.

This chapter contains the following man pages:

- `pbs_module(7B)`
- `pbs_stathook(3B)`

See the following additional man pages:

- `qmgr(1B)`
- `qsub(1B)`
- `qmove(1B)`
- `qalter(1B)`
- `pbs_rsub(1B)`
- `pbs_manager(3B)`

28.2 How Hooks Work

28.2.1 Hook Contents and Permissions

A hook contains a Python script. The script is evaluated by a Python 3 or later interpreter, embedded in PBS.

Hooks have a default Linux umask of 022. File permissions are inherited from the current working directory of the hook script.

28.2.2 Accepting and Rejecting Actions

The hook script always accepts the current event request action unless an unhandled exception occurs in the script, a hook alarm timeout is triggered or there's an explicit call to "pbs.event().reject()".

28.2.3 Exceptions

A hook script can catch an exception and evaluate whether or not to accept or reject the event action. In this example, while referencing the non-existent attribute pbs.event().job.interactive, an exception is triggered, but the event action is still accepted:

```
…
try:
    e = pbs.event()
    if e.job.interactive:
         e.reject("Interactive jobs not allowed")
except SystemExit:
    pass
except:
    e.accept()
```

28.2.4 Unsupported Interfaces and Uses

Site hooks which read, write, close, or alter `stdin`, `stdout`, or `stderr`, are not supported. Hooks which use any interfaces other than those described are unsupported.

28.3 Interface to Hooks

Two PBS APIs are used with hooks. These are `pbs_manager()` and `pbs_stathook()`. The pbs module provides a Python interface to PBS.

28.3.1 The pbs Module

Hooks have access to a special module called "pbs", which contains functions that perform PBS-related actions. This module must be explicitly loaded by the hook writer via the call "import pbs".

The *pbs module* provides an interface to PBS and the hook environment. The interface is made up of Python objects, which have attributes and methods. You can operate on these objects using Python code.

28.3.1.1 Description of pbs Module

28.4 pbs_module

The interface is made up of Python objects, which have attributes and methods. You can operate on these objects using Python code. For a description of each object, see the PBS Professional Administrator's Guide.

28.4.0.1 pbs Module Objects

See "The pbs Module" on page 82 in the PBS Professional Hooks Guide.

28.4.0.2 pbs Module Global Attribute Creation Methods

See "PBS Types and Their Methods" on page 168 in the PBS Professional Hooks Guide.

28.4.0.3 Attributes and Resources

See "Using Attributes and Resources in Hooks" on page 45 in the PBS Professional Hooks Guide.

28.4.0.4 Exceptions

See "Table of Exceptions" on page 44 in the PBS Professional Hooks Guide and "Hook Alarm Calls and Unhandled Exceptions" on page 44 in the PBS Professional Hooks Guide.

28.4.0.5 See Also

The *PBS Professional Administrator's Guide*, `pbs_hook_attributes(7B)`, `pbs_resources(7B)`, `qmgr(1B)`

28.4.1 The pbs_manager() API

The `pbs_manager()` API is described in "pbs_manager" on page 41.

The `pbs_manager()` API contains the following:

- An obj_name called "hook" defined as MGR_OBJ_HOOK, for use with non-built-in hooks
- An obj_name called "pbshook" defined as MGR_OBJ_PBS_HOOK, for use with built-in hooks.
- The following hook commands, which operate only on hook objects:

  MGR_CMD_IMPORT

  This command is used for loading the hook script contents into a hook.

  MGR_CMD_EXPORT

  This command is used for dumping to a file the contents of a hook script.

  The parameters to MGR_CMD_IMPORT and MGR_CMD_EXPORT are specified via the attrib parameter of `pbs_manager()`.

  For MGR_CMD_IMPORT, specify attropl "name" as "content-type", "content-encoding", and "input-file" along with the corresponding "value" and an "op" of SET.

  For MGR_CMD_EXPORT, specify attropl "name" as "content-type", "content-encoding", and "output-file" along with the corresponding "value" and an "op" of SET.

  Functions MGR_CMD_IMPORT, MGR_CMD_EXPORT, and MGR_OBJ_HOOK are used only with hooks, and therefore require root privilege on the server host.

  When obj_name is MGR_OBJ_PBS_HOOK, the only allowed options for command are MGR_CMD_SET, MGR_CMD_UNSET, MGR_CMD_IMPORT, and MGR_CMD_EXPORT.

If MGR_CMD_IMPORT or MGR_CMD_EXPORT is specified when obj_name is MGR_OBJ_PBS_HOOK, the attropl content-type must be "application/x-config".

28.4.1.1 Troubleshooting

You can use `pbs_geterrmsg()` to determine the last error message received from the `pbs_manager()` call. For instance, with a MGR_OBJ_PBS_HOOK where command is either MGR_CMD_IMPORT or MGR_CMD_EXPORT, but attropl 'content-type' is not "application/x-config", `pbs_geterrmsg()` returns:

```
"<content-type> must be application/x-config"
```

If an unrecognized hook configuration file suffix is given, whether for MGR_OBJ_HOOK or MGR_OBJ_PBS_HOOK, `pbs_geterrmsg()` returns:

```
"<input-file> contains an invalid suffix, should be one of: .json .py .txt .xml .ini"
```

If the hook configuration file failed to be precompiled by PBS, `pbs_geterrmsg()` shows:

```
"Failed to validate config file, hook '<hook_name>' config file not overwritten"
```

28.4.1.2 Privilege for Hooks

To run, hooks require root privilege on Linux, and local Administrators privilege on Windows.

28.4.1.3 Examples of Using pbs_manager()

Example 28-1: The following:

```
# qmgr -c 'import hook hook1 application/x-python base64 hello.py.b64'
```

is programmatically equivalent to:

```
static struct attropl imp_attribs[] = {
    {   "content-type",
        (char *)0,
        "application/x-python",
        SET,
        (struct attropl *)&imp_attribs[1]
    },
    {   "content-encoding",
        (char *)0,
        "base64",
        SET,
        (struct attropl *)&imp_attribs[2]},
    {   "input-file",
        (char *)0,
        "hello.py.b64",
        SET,
        (struct attropl *)0
    }
};

pbs_manager(con, MGR_CMD_IMPORT, MGR_OBJ_HOOK, "hook1", &imp_attribs[0], NULL);
```

Example 28-2: The following:

```
# qmgr -c 'export hook hook1 application/x-python default hello.py'
```

is programmatically equivalent to:

```
static struct attropl exp_attribs[] = {
    {   "content-type",
        (char *)0,
        "application/x-python",
        SET,
        (struct attropl *)&exp_attribs[1]},
    {   "content-encoding",
        (char *)0,
        "default",
        SET,
        (struct attropl *)&exp_attribs[2]},
    {   "output-file",
        (char *)0,
        "hello.py",
        SET,
        (struct attropl *)0
```

```
    }
};

pbs_manager(con, MGR_CMD_EXPORT, MGR_OBJ_HOOK, "hook1", &exp_attribs[0], NULL);
```

Example 28-3: The following:

```
# qmgr -c 'import pbshook hook1 application/x-config default hello.json'
```

is programmatically equivalent to:

```
static struct attropl imp_attribs[] = {
    {   "content-type",
        (char *)0,
        "application/x-config",
        SET,
        (struct attropl *)&imp_attribs[1]},
    {   "content-encoding",
        (char *)0,
        "default",
        SET,
        (struct attropl *)&imp_attribs[2]},
    {   "input-file",
        (char *)0,
        "hello.json",
    <   SET,
        (struct attropl *)0
    }
};

pbs_manager(con, MGR_CMD_IMPORT, MGR_OBJ_PBS_HOOK, "hook1", &imp_attribs[0], NULL);
```

Example 28-4: The following:

```
# qmgr -c 'export pbshook hook1 application/x-config default hello.json'
```

is programmatically equivalent to:

```
static struct attropl exp_attribs[] = {
    {   "content-type",
        (char *)0,
        "application/x-config",
        SET,
        (struct attropl *)&exp_attribs[1]},
    {   "content-encoding",
        (char *)0,
        "default",
        SET,
        (struct attropl *)&exp_attribs[2]},
    {   "output-file",
        (char *)0,
        "hello.json",
        SET,
        (struct attropl *)0
    }
};

pbs_manager(con, MGR_CMD_EXPORT,
MGR_OBJ_PBS_HOOK, "hook1", &exp_attribs[0], NULL);
```

28.4.2 The pbs_stathook() API

The PBS API called "pbs_stathook()" is used to get attributes and values for site hooks and built-in hooks.

The prototype for pbs_stathook() is as follows:

```
struct batch_status *pbs_stathook(int connect, char *hook_name, struct attrl *attrib, char
    *extend)
```

To query status for site hooks:

The call to pbs_stathook() causes a PBS_BATCH_StatusHook request to be sent to the server. In reply, the PBS server returns a batch reply status of object type MGR_OBJ_HOOK listing the attributes and values that were requested relating to a particular hook or all hooks of type HOOK_SITE. Leave the extend value blank.

To query status for built-in hooks:

Pass PBS_HOOK as the extend value. The server returns a batch reply status of object type MGR_OBJ_PBS_HOOK.

28.4.2.1 Example of Using pbs_stathook()

To list all site hooks using `qmgr`:

```
qmgr -c "list hook"
```

To list all site hooks using the `pbs_stathook()` API:

```
pbs_stathook()
```

The result is the same. For example, if there are two site hooks, c3 and c36:

```
Hook c3
    type = site
    enabled = true
    event = queuejob, modifyjob
    user = pbsadmin
    alarm = 30
    order = 1
Hook c36
    type = site
    enabled = true
    event = resvsub
    user = pbsadmin
    alarm = 30
    order = 1
```

28.5 pbs_stathook(3B)

get status information about PBS site hooks

28.5.1 Synopsis

#include <pbs_error.h>

#include <pbs_ifl.h>

*struct batch_status *pbs_stathook(int connect, char *hook_id, struct attrl *output_attribs, char *extend)*

*void pbs_statfree(struct batch_status *psj)*

28.5.2 Description

Issues a batch request to get the status of a specified site hook or a set of site hooks at the current server.

Generates a *Status Hook* batch request and sends it to the server over the connection specified by connect.

28.5.2.1 Required Privilege

This API can be executed only by root on the local server host.

28.5.3 Arguments

connect

Return value of `pbs_connect()`. Specifies connection handle over which to send batch request to server.

hook_id

Hook name, null string, or null pointer.

If *hook_id* specifies a name, the attribute-value list for that hook is returned.

If *hook_id* is a null string or a null pointer, the status of all hooks at the current server is returned.

output_attribs

Pointer to a list of attributes to return. If this list is null, all attributes are returned. Each attribute is described in an attrl structure, defined in `pbs_ifl.h` as:

```
struct attrl {
        char *name;
        char *resource;
        char *value;
        struct attrl *next;
};
```

extend

Character string where you can specify limits or extensions of your selection.

28.5.3.1 Members of attrl Structure

name

Points to a string containing the name of the attribute.

resource
: Points to a string containing the name of a resource. Used only when the specified attribute contains resource information. Otherwise, resource should be a null pointer.

value
: Should always be a pointer to a null string.

next
: Points to next attribute in list. A null pointer terminates the list.

28.5.4 Return Value

Returns a pointer to a list of batch_status structures for the specified site hook. If no site hook can be queried for status, returns the null pointer.

If an error occurred, the routine returns a null pointer, and the error number is available in the global integer pbs_errno.

28.5.4.1 The batch_status Structure

The batch_status structure is defined in pbs_ifl.h as

```
struct batch_status {
    struct batch_status *next;
    char *name;
    struct attrl *attribs;
    char *text;
}
```

28.5.5 Cleanup

You must free the list of batch_status structures when no longer needed, by calling pbs_statfree().

28.5.6 Error Messages

The following error message is returned by the pbs_geterrmsg() API after calling pbs_manager() operating on a hook object, with the MGR_CMD_IMPORT command, with "content-type" of "application/x-config":

```
"Failed to validate config file, hook 'submit' config file not overwritten"
```

If the input config file given is of unrecognized suffix, then the following message is returned by the pbs_geterrmsg() API after calling pbs_manager() operating on a hook object, MGR_CMD_IMPORT command with "content-type" of "application/x-config":

```
"<input-file> contains an invalid suffix, should be one of: .json .py .txt .xml .ini"
```

If you specify an unknown hook event, pbs_geterrmsg() returns the following after calling pbs_manager():

```
invalid argument (<bad_event>) to event.  Should be one or more of:
    queuejob,modifyjob,resvsub,movejob,runjob,provision,execjob_begin,execjob_prologue,execjob_e
    pilogue,execjob_preterm,execjob_end,exechost_periodic,execjob_launch,exechost_startup or ""
    for no event
```

If you specify an invalid value for a hook's debug attribute, the following error message appears in qmgr's stderr and is returned by pbs_geterrmsg() after calling pbs_manager():

```
"unexpected value '<bad_val>' must be (not case sensitive) true|t|y|1|false|f|n|0"
```

A runjob hook cannot set the value of a Resource_List member other than those listed in "Tables: Reading & Setting Built-in Job Resources in Hooks" on page 64 in the PBS Professional Hooks Guide. Setting any of the wrong resources results in the following:

- The hook request is rejected
- The following message is the output from calling `pbs_geterrmsg()` after the failed `pbs_runjob()`:

```
" request rejected by filter hook: '<hook name>' hook failed to set job's
    Resource_List.<resc_name> = <resc_value> (not allowed)"
```

29
Custom Authentication and Encryption Library APIs

This chapter describes LibAuth, which contains APIs you can use to create your own custom authentication or encryption library.

Call the `pbs_auth_set_config` API first before calling any other LibAuth API.

Table of Authentication and Encryption APIs

29.1 pbs_auth_set_config

specify configuration for authentication library

29.1.1 Synopsis

*void pbs_auth_set_config(const pbs_auth_config_t *auth_config)*

29.1.2 Description

Specifies configuration for the authentication library. Use this to specify logging method, where to find required credentials, etc.

Call this API first before calling any other LibAuth API.

29.1.3 Arguments

const pbs_auth_config_t *auth_config

Pointer to a configuration structure

29.1.4 Configuration Structure

typedef struct pbs_auth_config {

char *pbs_home_path;

Path to PBS_HOME directory (aka same value as PBS_HOME in pbs.conf). This must be a null-terminated string.

char *pbs_exec_path;

Path to PBS_EXEC directory (aka same value as PBS_EXEC in pbs.conf). This must be a null-terminated string.

char *auth_method;

Name of authentication method (aka same value as PBS_AUTH_METHOD in pbs.conf). This must be a null-terminated string.

char *encrypt_method;

Name of encryption method (aka same value as PBS_ENCRYPT_METHOD in pbs.conf). This must be a null-terminated string

void (*logfunc)(int type, int objclass, int severity, const char *objname, const char *text);

Function pointer to the logging method with the same signature as log_event from Liblog.

With this, the user of the authentication library can redirect logs from the authentication library into respective log files or stderr in case no log files.

If func is set to NULL then logs will be written to stderr (if available, else no logging at all).

} pbs_auth_config_t;

29.1.5 Return Value

None return value

29.2 pbs_auth_create_ctx

create authentication context

29.2.1 Synopsis

*int pbs_auth_create_ctx(void **ctx, int mode, int conn_type, char *hostname)*

29.2.2 Description

Creates an authentication context for a given mode and connection type. Context is used by other LibAuth APIs for authentication, encryption, and decryption of data.

29.2.3 Arguments

void **ctx

Pointer to auth context to be created

int mode

Specifies type of context to be created. Should be one of *AUTH_CLIENT* or *AUTH_SERVER*.

Use AUTH_CLIENT for client-side (who is initiating authentication) context

Use AUTH_SERVER for server-side (who is authenticating incoming user/connection) context

```
enum AUTH_ROLE {
    AUTH_ROLE_UNKNOWN = 0,
    AUTH_CLIENT,
    AUTH_SERVER,
    AUTH_ROLE_LAST
};
```

int conn_type

Specifies type of connection is for context to be created. Should be one of *AUTH_USER_CONN* or *AUTH_SERVICE_CONN*

Use AUTH_USER_CONN for user-oriented connection (such as when PBS client is connecting to PBS server)

Use AUTH_SERVICE_CONN for service-oriented connection (such as when PBS MoM is connecting to PBS server via PBS comm)

```
enum AUTH_CONN_TYPE {
    AUTH_USER_CONN = 0,
    AUTH_SERVICE_CONN
};
```

char *hostname

The null-terminated hostname of another authenticating party

29.2.4 Return Value

Integer.

0
: On Success

1
: On Failure

29.2.5 Cleanup

When a context created using this API is no longer required, destroy it via `auth_destroy_ctx.`

29.3 pbs_auth_destroy_ctx

destroy an authentication context created using `auth_create_ctx`

29.3.1 Synopsis

*void pbs_auth_destroy_ctx(void *ctx)*

29.3.2 Description

Destroys the authentication context created using `auth_create_ctx`

29.3.3 Arguments

void *ctx
: Pointer to authentication context to be destroyed

29.3.4 Return Value

No return value

29.4 pbs_auth_get_userinfo

extract username with its realm, and hostname of connecting party from authentication context

29.4.1 Synopsis

*int pbs_auth_get_userinfo(void *ctx, char **user, char **host, char **realm)*

29.4.2 Description

Extracts username with its realm, and hostname of the connecting party from the given authentication context.

The extracted user, host, and realm values are null-terminated strings.

This API is mostly useful for authenticating on the server side to get information about an authenticating client.

The authenticating server can use this information from the auth library to match against the actual username/realm/hostname provided by the connecting party.

29.4.3 Arguments

void *ctx
: Pointer to auth context from which information will be extracted

char **user
: Pointer to a buffer in which this API will write the username

char **host
: Pointer to a buffer in which this API will write hostname

char **realm
: Pointer to a buffer in which this API will write the realm

29.4.4 Return Value

Integer

0
: On success

1
: On failure

29.4.5 Cleanup

When the returned user, host, and realm are no longer required, free them using `free()`, since they use allocated heap memory.

29.4.6 Example

This example shows what the values of user, host, and realm will be. Let's use an example with GSS/Kerberos authentication, where the authentication client hostname is "xyz.abc.com", the username is "test", and in the Kerberos configuration, the domain realm is "PBSPRO". When the client authenticates to the server using the Kerberos authentication method, it is authenticated as "test@PBSPRO", and this API returns user = test, host = xyz.abc.com, and realm = PBSPRO.

29.5 pbs_auth_process_handshake_data

handle and generate handshakes, and generate handshake data

29.5.1 Synopsis

*int pbs_auth_process_handshake_data(void *ctx, void *data_in, size_t len_in, void **data_out, size_t *len_out, int *is_handshake_done)*

29.5.2 Description

Process incoming handshake data and do the handshake. If required generate handshake data which to be sent to another party. If there is no incoming data then initiate a handshake and generate initial handshake data to be sent to the authentication server.

29.5.3 Arguments

void *ctx
: Pointer to authentication context for which handshake is happening

void *data_in
: Incoming handshake data to process, if any. A NULL value indicates that this API should initiate a handshake and generate initial handshake data to be sent to the authentication server.

size_t len_in
: Length of incoming handshake data, if any, else 0

void **data_out
: Outgoing handshake data to be sent to another authentication party.

A NULL value indicates that the handshake is completed and no further data needs to be sent.

When this API returns 1 (failure), `data_out` contains the error message.

size_t *len_out
: Length of outgoing handshake/auth error data, if any, else 0

int *is_handshake_done
: Indicates whether handshake is completed or not.

0 means that the handshake is not completed.

1 means that the handshake is completed.

29.5.4 Return Value

Integer

0
: On success

1
: On failure

On failure, the value of `data_out` is the error data/message, to be sent to another authentication party as authentication error data.

29.5.5 Cleanup

When the returned `data_out` (if any) is no longer required, free it using `free()`, since it uses allocated heap memory.

29.6 pbs_auth_encrypt_data

encrypt data using specified authentication context

29.6.1 Synopsis

*int pbs_auth_encrypt_data(void *ctx, void *data_in, size_t len_in, void **data_out, size_t *len_out)*

29.6.2 Description

Encrypt given unencrypted data using the specified authentication context.

29.6.3 Arguments

void *ctx
: Pointer to auth context which will be used while encrypting given unencrypted data

void *data_in
: unencrypted data to encrypt

size_t len_in
: Length of unencrypted data

void **data_out
: Encrypted data

size_t *len_out
: Length of encrypted data

29.6.4 Return Value

Integer

0
: Success

1
: Failure

29.6.5 Cleanup

When the returned `data_out` is no longer required, free it using `free()`, since it uses allocated heap memory.

29.7 pbs_auth_decrypt_data

decrypt data

29.7.1 Synopsis

*int pbs_auth_decrypt_data(void *ctx, void *data_in, size_t len_in, void **data_out, size_t *len_out)*

29.7.2 Description

Decrypt encrypted data using the specified authentication context

29.7.3 Arguments

void *ctx
: Pointer to authentication context which will be used while decrypting given encrypted data

void *data_in
: Encrypted data to decrypt

size_t len_in
: Length of encrypted data

void **data_out
: Unencrypted data

size_t *len_out
: Length of unencrypted data

29.7.4 Return Value

Integer

0
: On success

1
: On failure

29.7.5 Cleanup

When the returned `data_out` is no longer required, free it using `free()`, since it uses allocated heap memory.

1 Introduction to PBS Cloud

1.1 Introduction to Cloud Bursting

PBS Cloud allows PBS Professional to burst nodes in the cloud, so that your site can handle demand peaks. PBS Professional uses Simulate and two cloud bursting hooks called cloud_hook and cloud_ext_hook to analyze jobs from the cloud queue(s), estimate the demand, and burst the required cloud nodes having the specified instance type and OS image. The PBS scheduler runs the jobs from the cloud queue in the cloud nodes. PBS Cloud dynamically adjusts the number of cloud nodes according to current load and how long you want nodes to wait for jobs to appear.

PBS Cloud provides the framework for the interface to the cloud. PBS Cloud supports multiple cloud vendors as well as private OpenStack clouds. You can use multiple vendors at the same time, and multiple accounts at each vendor. PBS Cloud also supports instance types that are on-demand, preemptable (GCP), spot (AWS and Azure), and bare metal. PBS Cloud supports jobs that use MPI and high speed networks such as InfiniBand.

PBS Cloud requires Simulate for cloud bursting. Simulate figures out how many nodes to burst and which jobs can run in each burst.

One PBS Cloud can handle cloud bursting for multiple PBS Professional complexes as long as all scenarios have different (unique) API keys.

1.2 Cloud Bursting Terminology

Burst

The action of creating a node in the cloud and adding it to the PBS complex

Cloud bursting hook (main)

The main cloud bursting hook is called "cloud_hook", and it is installed when you install PBS Cloud. The PBS cloud bursting hook manages cloud nodes and jobs via PBS Cloud and cloud queues. You specify details for each scenario that you want the hook to handle. The main cloud bursting hook handles bursting for all instances except bare metal, which are handled by the extension cloud bursting hook.

Cloud bursting hook (extension)

The extension cloud bursting hook is called "cloud_ext_hook", and you create it as a modified version of the main cloud bursting hook. The extension PBS cloud bursting hook handles bursting bare metal instances.

Cloud node

A virtual machine or instance that has been created on cloud hardware. Each cloud node is burst using the OS image specified for the job. After the node is burst, it is initialized via `cloud-init` scripts with everything required to run PBS jobs.

Cloud queue

Each scenario uses its own cloud queue. This is where the jobs for that scenario are enqueued. Cloud jobs must be submitted to the appropriate cloud queue.

Head node

Node where the PBS Professional server/scheduler are installed.

Instance type

A specification for an instance including characteristics such as CPUs, memory, storage capacity, network technology, etc. The PBS Cloud administrator specifies the instance types that will be available to job submitters. Jobs can request and use only instance types that the administrator has made available.

PBS Cloud supports instance types that are on-demand, preemptable (GCP), spot (AWS and Azure), and bare metal.

OS image

A pre-configured OS image in the cloud from which virtual machines can be instantiated. At the vendor, you create an OS image to use as the default for a particular scenario at that vendor. Jobs can request a specific OS image, the cloud bursting hook can specify a default OS image for that scenario, and you can set a default OS image for the cloud queue for that scenario.

Proximate node group

A group of nodes that are on the same high speed network. For example, a group of nodes that share a high speed switch, for example a group of nodes that are in one Azure InfiniBand scale set, or are in an Oracle instance pool.

Scenario

A bursting scenario encapsulates information needed to burst cloud nodes, such as the default OS image and which `cloud-init` script should initialize cloud nodes. You create a scenario data structure in PBS Cloud; this is where you specify information about resources provided by the cloud vendor that PBS Cloud uses for bursting. You define other aspects of the same scenario in the appropriate cloud bursting hook. A scenario can use one or more instance types to burst cloud nodes, with these restrictions:

- All the instance types for a scenario must be non-preemptable or be preemptable, but cannot be mixed
- All the instance types for a scenario must be non-bare-metal or bare metal, but cannot be mixed

You can have as many scenarios as you want.

Service node

Node where PBS Cloud module is installed.

Simulate

The PBS Professional workload simulation tool. See the *PBS Professional Simulate Guide*.

Unburst

The action of removing a node from both the PBS complex and the cloud.

Workflow

The process of bursting one or more nodes in the cloud. See section 7.6.3, “Examining Node Bursting Workflows”, on page 168.

1.3 How PBS Cloud Bursting Works

1.3.1 How Node Bursting Works

You create an administrator account with your cloud vendor. PBS Cloud uses this vendor administrator account to manage cloud nodes.

You create a cloud queue for each scenario, and job submitters request the cloud queue for their cloud jobs. The PBS scheduler runs the cloud jobs in the cloud nodes.

PBS Simulate analyzes the resources needed by cloud jobs, figures out how many and what type of nodes to burst, and which jobs to run.

One of the cloud bursting hooks bursts the nodes: if the required nodes are not on bare metal, the main cloud bursting hook bursts the required cloud nodes via PBS Cloud, but if the required nodes are on bare metal, the extension cloud bursting hook bursts the nodes.

Each hook uses existing nodes when possible, and bursts new nodes when needed.

The following illustration shows the relationships between PBS Professional, PBS Cloud, Simulate, and cloud providers.

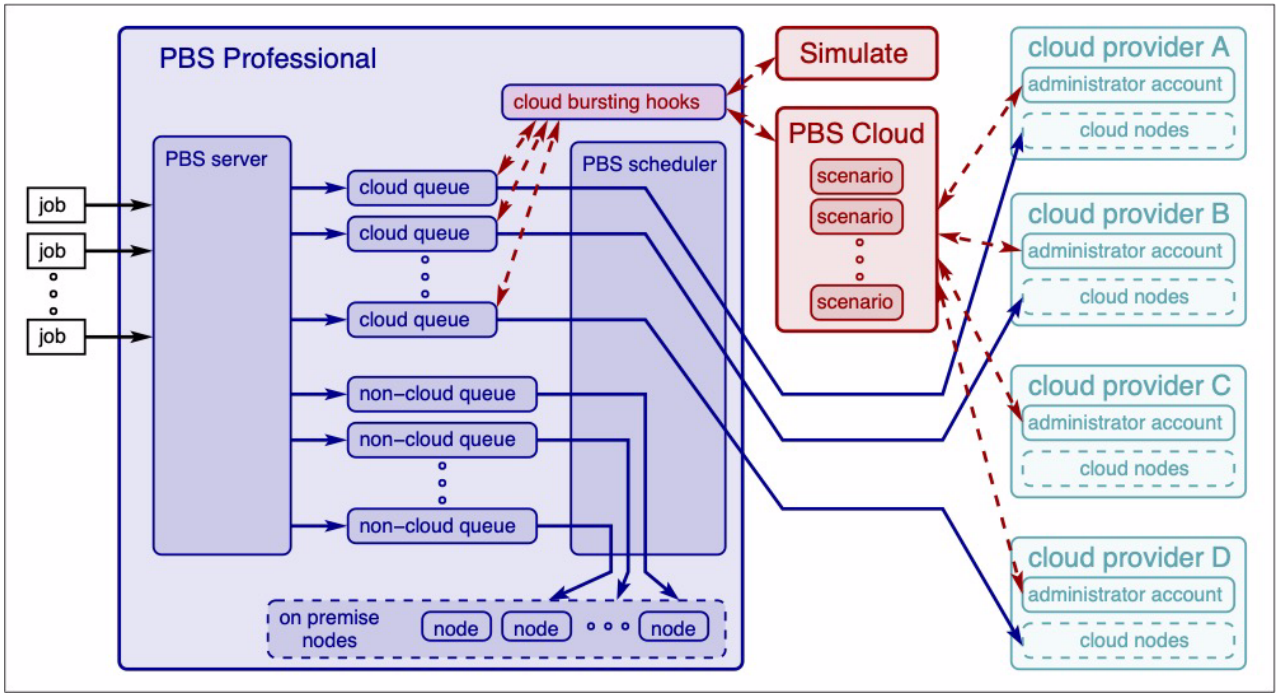

Figure 1-1: Relationships between PBS Professional, PBS Cloud, Simulate, and cloud providers

1.3.1.1 OS Image and Instance Type Assignment to Job

The OS image and instance type used for a particular job depend on whether the job requests it, or whether the job inherits it along the way. The OS image is specified via the cloud_node_image resource, and the instance type is specified via the cloud_node_instance_type resource. Assignment works in this order, with the first one encountered being the one assigned:

1. Job request
2. Queue default
3. Cloud bursting hook default
4. PBS Cloud scenario default

1.3.1.2 Main Cloud Bursting Hook and Extension Cloud Bursting Hook

The main cloud bursting hook is called "cloud_hook", and it bursts any non-bare-metal instances. The extension cloud bursting hook is called "cloud_ext_hook", and it bursts any bare-metal instances. The hooks are identical except for their configuration files (and names). All non-bare-metal instances are in scenarios defined in the configuration file for cloud_hook. All bare-metal instances are in scenarios defined in the configuration file for cloud_ext_hook.

You cannot mix bare-metal and non-bare-metal instances in the same scenario. You cannot mix bare-metal and non-bare-metal scenarios in the same hook configuration file.

1.3.2 Tracking Application Licenses

Jobs that run in the cloud may require application licenses. PBS Cloud bursts nodes for these jobs only when application licenses are available; otherwise the nodes could sit idle.

PBS Cloud uses a custom consumable server-level integer resource to track how many of each kind of application license are available. The cloud bursting hook checks the value of this resource before bursting cloud nodes, so that it only bursts new nodes for jobs requiring application licenses when those licenses are available. The administrator creates a script, typically run as a `cron` job, that keeps this resource as up-to-date as possible.

1.4 Distributing Jobs to Cloud and On Premise Nodes

The basic configuration for PBS Cloud allows job submitters to request nodes that are burst in the cloud for their jobs, as an alternative to requesting on premise nodes. With the basic configuration, jobs in cloud queues run in the cloud, and jobs in non-cloud queues run on premises. However, you may want more flexibility in where jobs run, and you can achieve this with some additional configuration:

- If you have the right resources on premises, it can make sense to run jobs residing in cloud queues on premises. The least expensive way to run a job is generally on premises, except for when you use spot pricing in some cases. However, jobs that run on spot instances may not be allowed to finish execution. You can configure on premise nodes to accept suitable cloud jobs; see section 3.2.8, “Running Cloud Queue Jobs On Premises”, on page 31.
- You may want to run non-cloud jobs in the cloud if for example they need to run right away. You can use a hook that examines jobs in non-cloud queues and moves them to suitable cloud queues; see section 3.2.9, “Running Non-Cloud Queue Jobs in the Cloud”, on page 31.

1.5 Licensing PBS Cloud Nodes

PBS Cloud is part of PBS Professional, and the licensing that you use for PBS Professional is used for PBS Cloud. For example, if you use PBSProNodes licenses for PBS Professional, you use that for PBS Cloud. Similarly, if you use PBSProSockets licenses for PBS Professional, that is the licensing for PBS Cloud.

1.6 Caveats and Restrictions for PBS Cloud

- The main cloud bursting hook can burst the nodes required for multiple jobs in a single burst, as long as those jobs do not require bare metal instances. The extension cloud bursting hook handles bursting for jobs requiring bare metal instances. This is because bursting to bare metal can slow the overall burst rate unacceptably when mixed with non-bare-metal.

2 Installing PBS Cloud

2.1 Supported Platforms

2.1.1 OpenSSL Requirement

PBS requires OpenSSL 1.1.1. If this is not already present on your platform, you must install it.

2.1.2 PBS Components

PBS Professional is made up of the following components:

- PBS Professional server/scheduler daemon on PBS Professional server/scheduler host/head node
- PBS Professional MoM daemon on execution host/compute node, with the following options:
  - On premise
  - Burst in cloud via PBS Cloud (optional)
- PBS Professional client commands on PBS submission host/client host
- PBS Professional communication daemon on communication host
- PBS Cloud module on service node (where AMS module runs) (optional)
- Budgets server on Budgets head node (optional)
- Budgets AMS module on service node (where PBS Cloud module runs) (optional)
- Budgets client commands on Budgets client host (optional)
- Simulate module:
  - When using PBS Cloud, Simulate must be installed on PBS Professional server/scheduler host
  - When not using PBS Cloud, Simulate can be installed on any supported host

2.1.3 Supported Platforms for PBS Components

PBS components are supported on the following platforms. A **(d)** indicates that support is deprecated:

Table 2-1: Supported Platforms

Maker	Version	Chip set	Components							
			PBS Professional				Cloud + AMS		Budgets	Simulate
			Server Sched	MoM on prem	Comm	Client cmds	Cloud module + AMS	MoM burst node	Head node + client cmds	Head node
CentOS	7	x86_64	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No
	7	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	No
Red Hat Enterprise Linux RHEL	7	x86_64	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
	7	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
	7 MLS	x86_64	Yes	Yes	Yes	Yes	No	No	No	No
	8	x86_64	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
	8	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
Rocky Linux	8	x86_64	Yes	Yes	Yes	Yes	No	Yes	No	No
	8	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	No
SUSE SLES	12	x86_64	Yes	Yes	Yes	Yes	Yes *	Yes	Yes	Yes
	12	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	No
	15	x86_64	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes
	15	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
Ubuntu	18.04	x86_64	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes
	18.04	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
	20.04	x86_64	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes
	20.04	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
HPE Cray Shasta	1.1 SLES 15	x86_64	Yes	Yes	Yes	Yes	Yes *	No	Yes *	Yes
	1.1 RHEL 7	x86_64	Yes	Yes	Yes	Yes	No	No	No	Yes
NEC SX-Aurora TSUBASA			Yes	Yes	Yes	Yes	No	No	No	Yes
Windows	10 Pro	x86_64	No	Yes	No	Yes	No	Yes	No	No

Table 2-1: Supported Platforms

Maker	Version	Chip set	Components							
			PBS Professional				Cloud + AMS		Budgets	Simulate
			Server Sched	MoM on prem	Comm	Client cmds	Cloud module + AMS	MoM burst node	Head node + client cmds	Head node
	11 Pro	x86_64	No	Yes	No	Yes	No	Yes	No	No
	Server 2016	x86_64	No	Yes	No	Yes	No	Yes	No	No
	Server 2019	x86_64	No	Yes	No	Yes	No	Yes	No	No

2.1.3.1 * SLES Restrictions for Cloud and Budgets Nodes

The following restrictions apply when using SLES on service node host for PBS Cloud or head node host for Budgets:

- Each SLES host must be registered with the SUSE Customer Center via SUSEConnect, and have a support contract. This happens automatically for cloud nodes.
- SLES hosts require Docker Enterprise Edition.

2.1.4 Supported Platforms for Nodes Burst in Cloud

- Linux: any Linux platform that supports both PBS MoM and `cloud-init`
- Windows: 10, Server 2012

All versions of `cloud-init` are supported.

2.1.5 Restrictions on Simulate Module Location when Using PBS Cloud

If you will use the PBS Cloud module, you must install Simulate on the PBS Professional server/scheduler host (the PBS Professional head node).

2.1.6 Supported Cloud Providers

You must already have an account with one of the supported cloud providers. We support the listed variant for each cloud provider:

Table 2-2: Supported Clouds

Cloud Provider	Variant
Microsoft Azure	Azure Compute
Amazon Web Services (AWS)	Elastic Compute Cloud (EC2)
Google Cloud Platform (GCP)	Compute Engine
Oracle Cloud Platform	Oracle Cloud Infrastructure
Orange Technical Cloud (OTC)	Orange Flexible
Deutsche Telekom	Open Telekom Cloud (OTC)
HUAWEI Cloud	Elastic Cloud Server
OpenStack cloud on premise	Stein

2.1.7 Minimum Hardware Requirements for PBS Cloud Host (Service Node)

2.1.7.1 Requirements for Connected Host

Minimum hardware requirements for connected PBS Cloud host (service node):

- Number of cores: 4
- RAM: 32GB
- Disk: 100GB

2.1.7.2 Requirements for Offline Host

Minimum hardware requirements for offline PBS Cloud host (service node):

- One host that is connected to the Internet, with:
  - Number of cores: 4
  - RAM: 32GB
  - Disk: 120GB
- An offline host where you will use PBS Cloud, with:
  - Number of cores: 4
  - RAM: 32GB
  - Disk: 130GB

2.2 Prerequisites

You can install PBS Cloud on a host that is connected to the Internet, or one that is not. We give instructions for both.

2.2.1 Software and Accounts

- A working PBS complex managed by PBS Professional version 2022.1.0. The PBS complex can be either of the recommended configurations in Recommended Configurations
- docker-ce v19.x or later for most systems
- docker-ee v19.x or later for SLES
- SELinux must be disabled
- VPN connection to the cloud you will use (unless the PBS server is hosted in the cloud)
- Cloud provider account with:
  - Correct authorizations
  - Approved method of payment

2.2.2 Licensing

Make sure that the time zone for your on premise hardware and all cloud nodes and your licenses is the same. You will also need the following:

- Altair License Server 14.5.1 or later
- PBSProNodes or PBSProSockets v20 license

2.2.3 Required Accounts

- To install PBS Cloud, you need to be root.
- To configure PBS Cloud, you must use pbsadmin@altair. This account is created by the PBS Cloud installer software during installation. The default password for pbsadmin@altair is Altair@123. We strongly recommend changing the password to something known only to you.

2.3 Recommended Configurations

The head node is where the PBS Professional server is installed. The service node is where the PBS Cloud module is installed.

The head node and service node can be one of either:

- Both on premises
- Both in cloud

Do not put one on premises and one in the cloud.

2.3.1 Recommended Configuration for Larger Installations

For larger installations using on premises hosts:

- On premises: head node (PBS server/scheduler), service node (PBS Cloud in a container), and on-premise execution nodes (on-premise MoMs)
- In cloud: burst execution nodes
- VPN connection to the cloud you will use

Notes:

- You may not want to run PBS Cloud on the PBS Professional head node, because PBS Cloud runs in a Docker container, which may impose too high a load on that node.
- All components are mix-and-match (with Docker restriction).
- You don't need to configure additional `pbs_comm` daemons for cloud nodes, because PBS Cloud can't cause enough throughput to need one.
- For PBS configuration instructions, see the *PBS Professional Administrator's Guide*.

2.3.2 Recommended Configuration for Smaller Installations

For smaller installations cloud-only installations where the workload is low enough:

- All PBS components can be hosted in the cloud
- All components can run on the same node
- You can run Docker on the same node as the PBS components

Notes:

- No VPN is required for this configuration
- We show an example of putting the PBS server and the PBS cloud module on the same node in Chapter 9, "Example Azure Head/Service Node", on page 173

2.4 Installation Steps

2.4.1 Installing on an Internet-connected Host

2.4.1.1 Install Docker

1. On the service node, log in as root
2. Install, start, and enable `docker-ce`:
   - For CentOS or RedHat:

     Log in to the machine where PBS Cloud is to be installed.

     ```
     yum install -y yum-utils
     yum-config-manager --add-repo https://download.docker.com/linux/centos/docker-ce.repo
     yum install docker-ce docker-ce-cli containerd.io
     systemctl enable docker
     systemctl start docker
     ```
   - For SLES12 or 15:

     Log in to the machine where PBS Cloud is to be installed.

     For SLES 12:

     ```
     sudo SUSEConnect -p sle-module-containers/12/x86_64 -r ''
     ```

     For SLES 15:

     ```
     sudo SUSEConnect -p sle-module-containers/15.1/x86_64 -r ''
     ```

     ```
     sudo zypper install docker
     sudo systemctl enable docker.service
     sudo systemctl start docker.service
     ```

     Configure the firewall to allow forwarding of Docker traffic to the external network:

     ```
     Set FW_ROUTE="yes" in /etc/sysconfig/SuSEfirewall2
     ```
   - For Ubuntu:

     Log in to the machine where PBS Cloud is to be installed.

     ```
     sudo apt-get update
     sudo apt-get install apt-transport-https ca-certificates curl gnupg-agent software-proper-
         ties-common
     curl -fsSL https://download.docker.com/linux/ubuntu/gpg | sudo apt-key add -
     sudo apt-key fingerprint 0EBFCD88
     ```

     The key should match the second line in the output; validate the last 8 characters. Example of second line:

     9DC8 5822 9FC7 DD38 854A E2D8 8D81 803C 0EBF CD88

     ```
     sudo add-apt-repository "deb [arch=amd64] https://download.docker.com/linux/ubuntu
         $(lsb_release -cs) stable"
     sudo apt-get update
     sudo apt-get install docker-ce docker-ce-cli containerd.io
     sudo systemctl enable docker.service
     sudo systemctl start docker.service
     ```

2.4.1.2 Install the PBS Cloud Module

1. On the service node, log in as root
1. Make backups of your cloud bursting hook configuration files:
   ```
   qmgr -c "export hook cloud_hook application/x-config default" > cloud_config.json.backup
   qmgr -c "export hook cloud_ext_hook application/x-config default" > cloud_ext_config.json.backup
   ```
2. Clean up any previous installations of the PBS Cloud module:
   - If the PBS cloud hook, named "cloud_hook", exists, delete it:
     ```
     qmgr -c 'd h cloud_hook'
     ```
   - If the PBS cloud extension hook, named "cloud_ext_hook", exists, delete it:
     ```
     qmgr -c 'd h cloud_ext_hook'
     ```
   - If the `pclm` command exists in `$PBS_EXEC/bin` or `/opt/pbs/bin`, delete it:
     ```
     source /etc/pbs.conf
     rm $PBS_EXEC/bin/pclm
     ```
3. Extract the installer:
   ```
   tar xvfz PBSPro-cloud_2022.1.0-<OS>_x86_64.tar.gz
   ```
4. To install PBS cloud module, main PBS cloud hook, and PBS Cloud command layer, execute the installation script:
   a. Change directory to `pbspro-cloud-installer` directory:
      ```
      cd pbspro-cloud-installer
      ```
   b. We strongly recommend changing the administrator password before installing PBS Cloud. Edit `install.sh` and replace the default administrator password (*Altair@123*) with a new password:
      `PBSCLOUD_PASSWORD=<new password>`
   c. Run the installer:
      ```
      .install.sh
      ```

2.4.1.3 Allow Easy PBS Cloud Status Check

1. Log in as root
2. Create an alias to easily use `pkr`. Type the following all one line:

alias pkr="docker run -ti --network host --rm -e PBSCLOUD_VERSION=pbspro-cloud-2022.1.0 -e PKR_VERSION=pbspro-cloud-2022.1.0 -v /run/docker.sock:/run/docker.sock -v /root/kard:/pkr/kard pbsclou-dio.azurecr.io/pkr:pbspro-cloud-2022.1.0 pkr"

2.4.1.4 Configure PBS Cloud to Use SSL Connections

You will probably want PBS Cloud to use SSL connections in order to protect your data while it is in transit. You can use a self-signed certificate or one that is signed by a certificate authority. The file names and formats for a certificate from a certificate authority may be different. If you need help, contact Altair Support. The .pem format is the most common; we provide an example of that here. On the service node:

1. Provide SSL certificates.
   - Example of creating a self-signed certificate:

     ```
     openssl req -new > cert.csr
     openssl rsa -in privkey.pem -out key.pem
     openssl x509 -in cert.csr -out cert.pem -req -signkey key.pem -days 1001
     cat key.pem>>cert.pem
     ```

2. Optionally save your certificates in a persistent location, such as /root/certificates/ so that they are not deleted if you re-install PBS Cloud.
3. Stop and remove all PBS Cloud containers:

   ```
   pkr stop
   pkr clean
   ```

4. Edit /root/kard/current/meta.yml:

   Look for this line:

   ```
   ui_port: 9980:
   ```

   Just below it, insert these new lines:

   ```
   ui_https_port: 443
   ssl_certificate: /<full path to cert>/cert.pem
   ssl_private_key: /<full path to key>/key.pem
   ```

   Make sure that your new lines come before this line:

   ```
   watch_ui: false
   ```

   For example, you end up with:

   ```
   ...
   ui_port: 9980:
   ui_https_port: 443
   ssl_certificate: /root/certificates/cert.pem
   ssl_private_key: /root/certificates/key.pem
   watch_ui: false
   ```

5. Push your changes into the PBS Cloud module:

   ```
   pkr kard make
   pkr start
   ```

2.4.1.5 Test the Installation

1. Log in as root
2. Make sure that relevant services are up and running. Each should have an IP address. See section 10.2.4, "Sample pkr Output while Running", on page 187 for sample healthy output reference data for `pkr`.

   ```
   pkr ps
   ```
3. If you are running the PBS Cloud module on a service node in the cloud, use the vendor tools to open access through the firewall to port 9980 so that you can use the vendor web interface.
4. Log into PBS Cloud from your web browser:

   ```
   http://<PBS Cloud host name or IP address>:<port>/pbspro-cloud/#/login
   ```
   - Default port: 9980
   - Username: pbsadmin@altair
   - Password: <administrator password> (Default is *Altair@123*)

2.4.2 Installing on an Offline Host

In order to install PBS Cloud on an offline host, you download the standard installation package on a connected host, extract the package, download Altair files to the package, tar it back up, copy it over to the offline host, untar it, and run the offline installer. We detail the steps below.

2.4.2.1 Install Docker on Connected Host

1. Log in as root on the service node
2. Install, start, and enable `docker-ce`:
   - For CentOS or RedHat:

     Log in to the machine where PBS Cloud is to be installed.

     ```
     yum install -y yum-utils
     yum-config-manager --add-repo https://download.docker.com/linux/centos/docker-ce.repo
     yum install docker-ce docker-ce-cli containerd.io
     systemctl enable docker
     systemctl start docker
     ```
   - For SLES12 or 15:

     Log in to the machine where PBS Cloud is to be installed.

     For SLES 12:

     ```
     sudo SUSEConnect -p sle-module-containers/12/x86_64 -r ''
     ```

     For SLES 15:

     ```
     sudo SUSEConnect -p sle-module-containers/15.1/x86_64 -r ''
     sudo zypper install docker
     sudo systemctl enable docker.service
     sudo systemctl start docker.service
     ```

     Configure the firewall to allow forwarding of Docker traffic to the external network:

     ```
     Set FW_ROUTE="yes" in /etc/sysconfig/SuSEfirewall2
     ```
   - For Ubuntu:

     Log in to the machine where PBS Cloud is to be installed.

     ```
     sudo apt-get update
     sudo apt-get install apt-transport-https ca-certificates curl gnupg-agent software-proper-
         ties-common
     curl -fsSL https://download.docker.com/linux/ubuntu/gpg | sudo apt-key add -
     sudo apt-key fingerprint 0EBFCD88
     ```

     The key should match the second line in the output; validate the last 8 characters. Example of second line:

     9DC8 5822 9FC7 DD38 854A E2D8 8D81 803C 0EBF CD88

     ```
     sudo add-apt-repository "deb [arch=amd64] https://download.docker.com/linux/ubuntu
         $(lsb_release -cs) stable"
     sudo apt-get update
     sudo apt-get install docker-ce docker-ce-cli containerd.io
     sudo systemctl enable docker.service
     sudo systemctl start docker.service
     ```

2.4.2.2 Download Installation Tarball to Connected Host

On the connected host:

1. Log in as root
2. Extract the contents of the installer package:

   ```
   tar xvfz PBSPro-cloud_2022.1.0-<OS>_x86_64.tar.gz
   ```

This creates the directory named "pbspro-cloud-installer"

3. Run the script that uses Docker to pull images from the Altair site and adds them to installer:
   a. Change directory to `pbspro-cloud-installer` directory:
      ```
      cd pbspro-cloud-installer
      ```
   b. Make the scripts executable:
      ```
      chmod 0755 *.sh
      ```
   c. Run the download script:
      ```
      .offline_download.sh
      ```
4. Tar up the modified installer:
   ```
   tar cvfz PBSPro-cloud_2022.1.0-CentOS7_x86_64_offline.tar.gz pbspro-cloud-installer/
   ```

2.4.2.3 Copy Tarball to Offline Host

Copy the tarball of the modified installation script onto the offline host.

2.4.2.4 Install Docker on Offline Host

On the offline host (service node):

1. Log in as root
2. Install Docker and its dependencies
   - For CentOS, RedHat, and Ubuntu, install `docker-ce` (Docker Community Edition) and its dependencies:
     `docker-ce`
     `docker-ce-cli`
     `containerd.io`
   - For SLES 12 and 15, install `docker-ee` (Docker Enterprise Edition). You may need to use SUSEConnect.
3. Enable Docker
4. Start Docker

2.4.2.5 Extract Tarball to Offline Host

On the offline host:

1. Make backups of your cloud bursting hook configuration files:
   ```
   qmgr -c "export hook cloud_hook application/x-config default" > cloud_config.json.backup
   qmgr -c "export hook cloud_ext_hook application/x-config default" >
   cloud_ext_config.json.backup
   ```
2. Clean up any previous installations of the PBS Cloud module:
   - If the PBS cloud hook, named "cloud_hook", exists, delete it:
     ```
     qmgr -c 'd h cloud_hook'
     ```
   - If the PBS cloud extension hook, named "cloud_ext_hook", exists, delete it:
     ```
     qmgr -c 'd h cloud_ext_hook'
     ```
   - If the `pclm` command exists in `$PBS_EXEC/bin` or `/opt/pbs/bin`, delete it:
     ```
     source /etc/pbs.conf
     rm $PBS_EXEC/bin/pclm
     ```
3. Untar the package for the modified installer:

   ```
   tar xvfz PBSPro-cloud_2022.1.0-CentOS7_x86_64_offline.tar.gz
   ```

   This creates the directory named "pbspro-cloud-installer"
4. Run the script for installing PBS Cloud on an offline host:
   a. Change directory to `pbspro-cloud-installer` directory:
      ```
      cd pbspro-cloud-installer
      ```
   b. We strongly recommend changing the administrator password before installing PBS Cloud. Edit `offline_install.sh` and replace the default administrator password (*Altair@123*) with a new password:
      `PBSCLOUD_PASSWORD=<new password>`
   c. Run the offline installation script:
      ```
      ./offline_install.sh
      ```

2.4.2.6 Allow Easy PBS Cloud Status Check

On the offline host:

1. Log in as root
2. Create an alias to easily use `pkr`. Type the following all one line:

   ```
   alias pkr="docker run -ti --network host --rm -e PBSCLOUD_VERSION=pbspro-cloud-2021.1 -e
   PKR_VERSION=pbspro-cloud-2021.1 -v /run/docker.sock:/run/docker.sock -v /root/kard:/pkr/kard
   pbscloudio.azurecr.io/pkr:pbspro-cloud-2021.1 pkr"
   ```

2.4.2.7 Configure PBS Cloud to Use SSL Connections

You will probably want PBS Cloud to use SSL connections in order to protect your data while it is in transit. You can use a self-signed certificate or one that is signed by a certificate authority. The file names and formats for a certificate from a certificate authority may be different. If you need help, contact Altair Support. The .pem format is the most common; we provide an example of that here. On the service node:

1. Provide SSL certificates
   - Example of creating a self-signed certificate:

     ```
     openssl req -new > cert.csr
     openssl rsa -in privkey.pem -out key.pem
     openssl x509 -in cert.csr -out cert.pem -req -signkey key.pem -days 1001
     cat key.pem>>cert.pem
     ```

2. Optionally save your certificates in a persistent location, such as /root/certificates/ so that they are not deleted if you re-install PBS Cloud.
3. Stop and remove all PBS Cloud containers:

   ```
   pkr stop
   pkr clean
   ```

4. Edit /root/kard/current/meta.yml:

   Look for this line:

   ```
   ui_port: 9980:
   ```

   Just below it, insert these new lines:

   ```
   ui_https_port: 443
   ssl_certificate: /<full path to cert>/cert.pem
   ssl_private_key: /<full path to key>/key.pem
   ```

   Make sure that your new lines come before this line:

   ```
   watch_ui: false
   ```

   For example, you end up with:

   ```
   ...
   ui_port: 9980:
   ui_https_port: 443
   ssl_certificate: /root/certificates/cert.pem
   ssl_private_key: /root/certificates/key.pem
   watch_ui: false
   ```

5. Push your changes into the PBS Cloud module:

   ```
   pkr kard make
   pkr start
   ```

2.4.2.8 Test the Installation

On the offline host:

1. Log in as root
2. Make sure that relevant services are up and running. Each should have an IP address. See section 10.2.4, “Sample pkr Output while Running”, on page 187 for sample healthy output reference data for `pkr`.

   ```
   pkr ps
   ```

3. If you are running the PBS Cloud module on a service node in the cloud, use the vendor tools to open access through the firewall to port 9980 so that you can use the vendor web interface.
4. Log into PBS Cloud from your web browser:

   `http://<PBS Cloud host name or IP address>:<port>/pbspro-cloud/#/login`

   - Default port: 9980
   - Username: pbsadmin@altair
   - Password: <administrator password> (Default is *Altair@123*)

2.5 Create Extension Cloud Bursting Hook

If you want to burst instances on bare metal (currently this means using Oracle's InfiniBand on bare metal), create the extension cloud bursting hook. We recommend naming this hook "cloud_ext_hook". The extension cloud bursting hook is identical to the main cloud bursting hook; the difference is in their configuration files. We show you how to set up the configuration files later in section 4.2, “Configuring the Cloud Bursting Hooks”, on page 55.

Steps to create the extension cloud bursting hook:

1. Export the main cloud bursting hook to a file:

   ```
   qmgr -c "export hook cloud_hook application/x-python default" > cloud_hook.py
   ```

2. Import the file to a hook named "cloud_ext_hook":

   ```
   qmgr -c "import hook cloud_ext_hook application/x-python default cloud_hook.py"
   ```

2.6 Install and Configure Simulate

PBS Cloud requires Simulate for cloud bursting. Simulate figures out how many nodes to burst and which jobs can run in each burst.

1. Install Simulate on the PBS Professional server/scheduler host (the PBS head node); follow the instructions in section 1.4, “Installation”, on page 4 of the *PBS Professional Simulate Guide*.
2. Configure Simulate; follow the instructions in section 1.5, “Configuration”, on page 4 of the *PBS Professional Simulate Guide*.

3 Configuring PBS Cloud

3.1 Overview of Configuring PBS Cloud

Much of the information required to configure PBS Cloud and PBS Professional is generated or chosen while you are logged into your cloud provider, building your cloud components. We provide a list of what to collect while you are doing this so that you will have the information you need later. Alternatively, you may want to have one window open for each purpose simultaneously, rather than performing these steps in sequence. We recommend reading through the instructions once before starting so that you can see where information is transferred from one tool to another.

The following is an overview of the steps involved; you can use this as a checklist. We cover the actual steps in detail elsewhere.

1. If you have not done so already, install PBS Professional; see the *PBS Professional Installation & Upgrade Guide*
2. If you have not done so already, install the PBS Cloud module; see Chapter 2, "Installing PBS Cloud", on page 5
3. If you have not done so already, install and configure the PBS Simulate module; see section 2.6, “Install and Configure Simulate”, on page 19
4. Configure PBS Professional for cloud bursting. This step is covered in section 3.2, “Configuring PBS Professional for Cloud Bursting”, on page 24, but we outline it here for clarity:
    a. Log into the PBS server host as administrator
    b. Configure PBS Professional for bursting to cloud nodes
        1. Create and configure resources
        1. Create and configure cloud queue(s)
        1. Modify non-cloud queues and nodes to prevent cloud jobs from running on-premise and spanning on-premise and cloud nodes
        2. Configure scheduling
        3. Use authentication and encryption; see section 3.2.7, “Use Authentication and Encryption”, on page 31
5. Log into your cloud provider
6. PBS Cloud will use an account at the cloud provider to manage cloud nodes. Create a cloud provider account for this purpose; see section 3.3.2, “Create Your Cloud Provider Account”, on page 32.

7. Build and configure your cloud components. During this step, capture the information listed; while you are generating or selecting each item, we'll remind you to collect it. You will use this information in the following steps here. Building and configuring cloud components is different for each cloud provider; use the provider-specific instructions in Chapter 5, "Using Cloud Provider Services", on page 67. We show an outline here so you can see what is covered:
   a. Log into your cloud provider
   b. Create the necessary cloud provider components, such as a virtual network
   c. Create a virtual machine
   d. Install the PBS Professional MoM, and other required software in the VM, including `cloud-init`
   e. If you will use `cloud-init` to configure freshly burst nodes, create a startup script for configuring burst nodes; see Chapter 6, "The Cloud Node Startup Script", on page 155
   f. Create the OS image to be used for bursting
8. Configure PBS Cloud. This step is described in section 3.3, “Configuring PBS Cloud”, on page 31, but we give you an idea of what's involved here:
   a. Log into PBS Cloud; see section 3.3.1, “Log Into PBS Cloud”, on page 31
   b. Add your cloud provider account to PBS Cloud; see section 3.3.3, “Add Your Provider Account to PBS Cloud”, on page 32
   c. Create a bursting scenario; see section 3.3.4, “Create a Bursting Scenario”, on page 35
   d. Manually test bursting; see section 6.3, “Developing the Startup Script”, on page 159
   e. For each remaining scenario, create and test the scenario
   f. Disable public IP addresses for the scenario
9. Configure the PBS cloud bursting hooks; see section 4.1, “The Cloud Bursting Hooks”, on page 53
   a. Log into the PBS server host as administrator
   b. Configure and enable the cloud hooks
   c. For each scenario, test it with the cloud hook by using it to automatically burst scenario nodes; see section 4.3, “Testing Automated Cloud Bursting”, on page 63
10. To prevent running out of PBSProNodes licenses, set a limit on the number of cloud nodes that can exist simultaneously. See section 3.3.6, “Managing Node Licenses”, on page 48

3.1.1 Overview of Creating Bursting Scenarios

We take you through the steps to define your bursting scenarios later during the instructions. But it helps to know why you are doing each step, so we summarize what's involved here. Each scenario is defined in all of the following:

- The scenario interface in PBS Cloud, where you set parameters such as the scenario name, and generate an API key for the scenario; see section 3.3.4, “Create a Bursting Scenario”, on page 35. PBS Cloud stores the API key you generate using the PBS Cloud interface.
- The matching scenario subsection in the relevant cloud bursting hook, where you set hook configuration parameters for that scenario, including the API key you generated via the PBS Cloud interface and the scenario name; see section 4.2.4, “Defining a Scenario in a Cloud Bursting Hook Configuration File”, on page 59
- The matching queue, where you set the value of resources_available.cloud_scenario to the exact name you used in the matching scenario subsection for the relevant cloud bursting hook. You create the matching queue; see section 3.2.5, “Create and Configure Cloud Queues”, on page 29. Each scenario requires its own cloud queue, and vice versa.

Each scenario is identified via an API key and a name. The API key ties the cloud bursting hook configuration file to the matching PBS Cloud scenario definition. The scenario name ties the cloud bursting hook configuration file to the matching queue. The following figure illustrates the relationships between a scenario definition in the PBS Cloud interface, a cloud bursting hook configuration file, and a cloud queue.

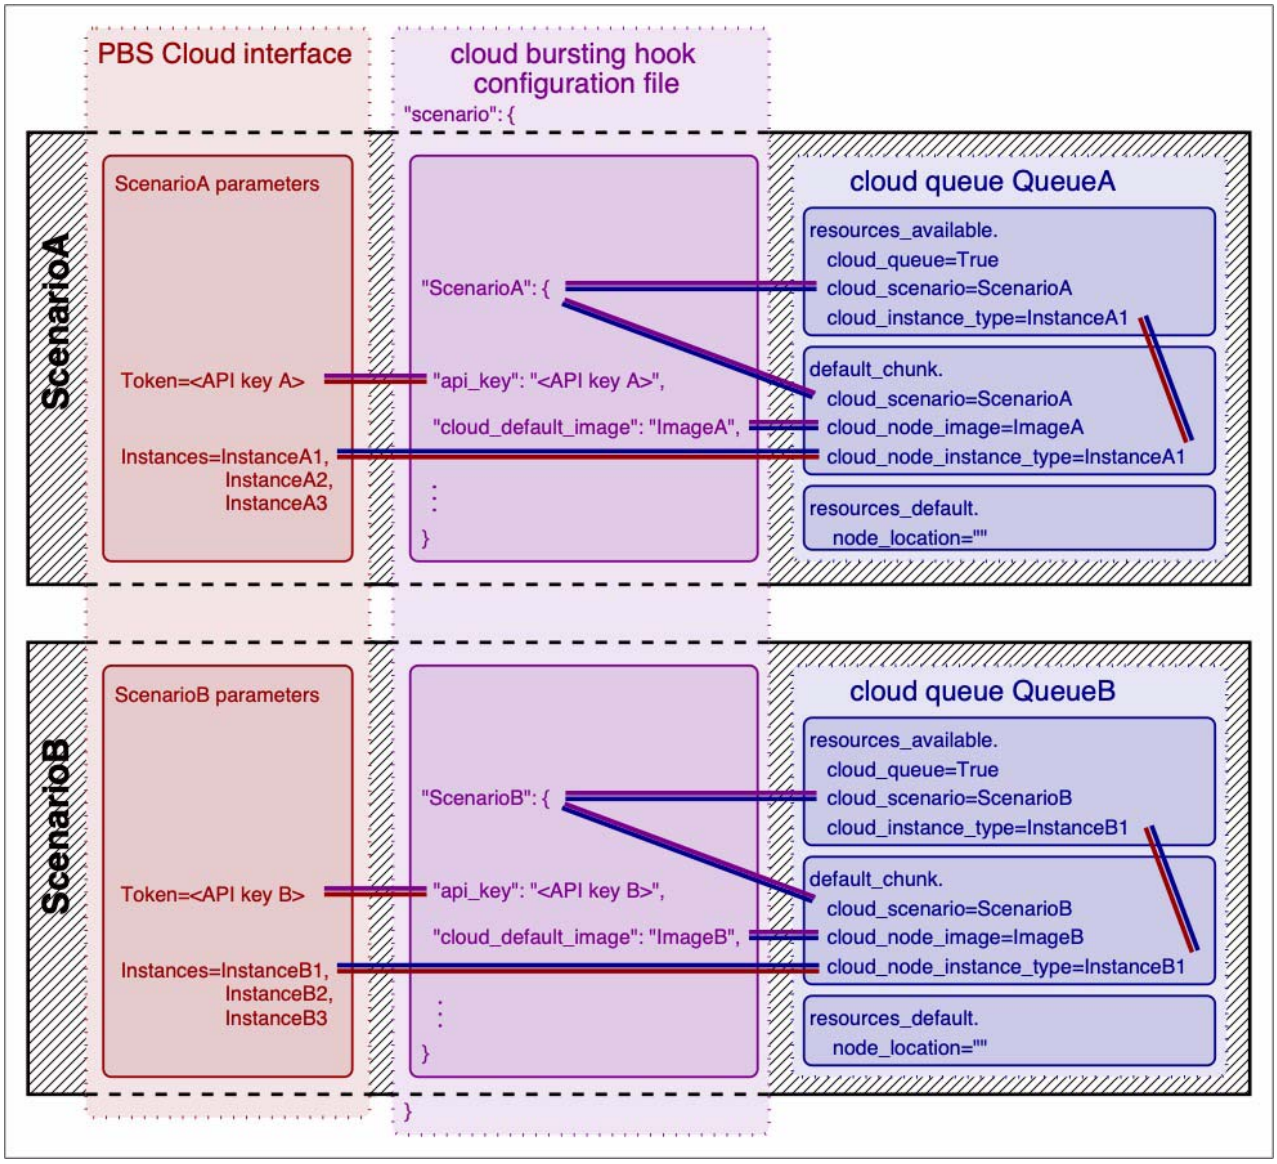

Figure 3-1: Relationships between a scenario definition in the PBS Cloud interface, a cloud bursting hook configuration file, and a cloud queue

The *Scenario Name* parameter in the PBS Cloud scenario interface is not used for scenario identification. However, we recommend making it the same as the name that you use in the cloud bursting hook configuration file and the cloud queue to make debugging easier.

3.2 Configuring PBS Professional for Cloud Bursting

3.2.1 List of PBS Professional Custom Resources for Cloud Bursting

PBS Professional uses the following custom resources to manage cloud jobs:

burst_by_hook
: Used by cloud bursting hooks to distinguish manually burst cloud nodes from automatically burst cloud nodes. Do not set.

cloud_account
: Queue-level string

Cloud account associated with this queue.

cloud_instance_type
: Queue-level string

Default cloud provider instance type (machine, shape type or flavor) associated with the scenario for this queue.

Make sure you choose an instance type that is enabled in PBS Cloud.

Note that the value of default_chunk.cloud_node_instance_type at this queue needs to be the same as resources_available.cloud_instance_type.

cloud_min_instances
: Server-level integer

Minimum number of cloud nodes (instances) to be present in the cloud at any time.

cloud_max_instances
: Server-level integer

Maximum number of cloud nodes (instances) that can be present in the cloud at any time.

cloud_max_jobs_check_per_queue
: **Deprecated**.

Queue-level integer

Maximum number of jobs in this cloud queue to be checked to determine the number of cloud nodes that must be burst based on the requested instance type. The relevant cloud bursting hook computes the number of nodes it must burst in order to run the checked cloud jobs. For example, if the instance type has 2 CPUs, and the first 3 jobs in the queue need a total of 10 CPUs, the hook bursts 5 nodes.

Must be greater than zero. Setting this to zero results in no jobs from this queue being considered for cloud bursting.

Default: 64

cloud_network
: Host-level string

For requesting nodes on a high-speed network (a proximate node group). All nodes will have the same network name.

Replaces the CLOUD_NETWORK environment variable for job requests.

cloud_node_image

Host-level string

Specifies OS image for a cloud job.

When set at a queue, this is the default scenario OS image to use when bursting a cloud node. Value at queue is overridden by image specified in a job.

Set default_chunk.cloud_node_image for a queue to the exact OS image specified in its cloud_default_image scenario parameter.

Replaces the CLOUD_IMAGE environment variable for job requests.

cloud_node_instance_type

Host-level string

Set the value for default_chunk.cloud_node_instance_type at the cloud queue to the value of the resources_available.cloud_instance_type queue resource.

This is set at the cloud node by the relevant cloud bursting hook when that node is burst.

If a job requests an instance type, that overrides the default set at the queue.

Replaces CLOUD_INSTANCE environment variable for job requests.

cloud_provisioned_time

Host-level integer

Time in seconds since the relevant cloud bursting hook started bursting cycle; if node doesn't successfully come up in that time, the cloud bursting hook tries again

cloud_queue

Queue-level Boolean

Indicates whether the queue is a cloud queue. When *True*, the queue is a cloud queue. The cloud bursting hooks analyze jobs in cloud queues.

cloud_scenario

Host-level string.

Scenario associated with this queue. One value per queue. Set in resources_available.cloud_scenario at queue to indicate scenario associated with queue. Set in default_chunk.cloud_scenario at queue to force each job chunk to run on node that has same scenario as queue.

lic_signature

Host-level string

Contains licensing information.

node_location

Host-level string. Arbitrary.

Used to differentiate on-premise nodes from cloud nodes. Lets you keep a job either all in the cloud or all on premise. On cloud nodes, if you have multiple clouds, we recommend that you name this for the cloud. For on-premise nodes, we recommend using something like "local" or "on-prem".

(static resource to represent each application license)

Consumable server-level integer

Each application license is represented by one static and one dynamic resource. Used by cloud bursting hooks to track license availability.

(dynamic resource to represent each application license)

Consumable server-level integer

Each application license is represented by one static and one dynamic resource. Used by cloud bursting hooks to track license availability.

3.2.2 Create Custom Resources for Cloud Bursting

1. Log in to the PBS server host as the PBS administrator
2. Create the custom resources required for cloud bursting:

```
qmgr -c 'create resource cloud_queue type=boolean'
qmgr -c 'create resource cloud_instance_type type=string'
qmgr -c 'create resource cloud_node_instance_type type=string,flag=h'
qmgr -c 'create resource cloud_min_instances type=long'
qmgr -c 'create resource cloud_max_instances type=long'
qmgr -c 'create resource cloud_provisioned_time type=long,flag=h'
qmgr -c 'create resource lic_signature type=string,flag=h'
qmgr -c 'create resource cloud_node_image type=string,flag=h'
qmgr -c 'create resource cloud_network type=string,flag=h'
qmgr -c 'create resource node_location type=string,flag=h'
qmgr -c 'create resource cloud_scenario type=string,flag=h'
qmgr -c 'create resource burst_by_hook type=boolean'
qmgr -c 'create resource cloud_account type=string'
```

3.2.3 Configure PBS Server and Scheduler for Cloud Bursting

1. Log in to the PBS server host as the PBS administrator
2. Set server limits:

```
qmgr -c "set server resources_available.cloud_min_instances = 0"
qmgr -c "set server resources_available.cloud_max_instances = <max nodes>"
```

3. Enable placement sets (if not enabled) and group on node_location:

```
qmgr -c "set server node_group_enable=true"
qmgr -c "set server node_group_key+=node_location"
```

4. Allow creation of placement sets from unset resources:

```
qmgr -c "set sched only_explicit_psets=false"
```

5. Prevent any single job from running on both local and cloud vnodes:

```
qmgr -c "set sched do_not_span_psets=true"
```

6. Make sure that the scheduler log level is set to at least *767* (the default). Otherwise bursting does not work:

```
qmgr -c 'set sched <scheduler name> log_events=767'
```

7. Change directory to `$PBS_HOME/sched_priv`
8. Edit the `sched_config` file. Add cloud_scenario, cloud_node_image, cloud_node_instance_type, and node_location to the `resources:` line:

```
resources: "ncpus, mem, arch, host, vnode, netwins, aoe, cloud_scenario, cloud_node_image,
    cloud_node_instance_type, node_location"
```

Do not add cloud_network to the `resources:` line.

9. Make the scheduler reread its configuration file; HUP the scheduler:

   ```
   kill -HUP <scheduler PID>
   ```

3.2.4 Manage Application Licenses for Cloud Jobs

If the cloud jobs at your site are not using externally-managed application licenses, you can skip this step.

Jobs that run in the cloud may require application licenses. PBS Cloud bursts nodes for these jobs only when application licenses are available; otherwise the nodes could sit idle.

PBS Cloud uses a custom consumable server-level integer resource to track how many of each kind of application license are available. The cloud bursting hooks check the value of this resource before bursting cloud nodes, so that they only burst new nodes for jobs requiring application licenses when those licenses are available. The administrator creates a script, typically run as a `cron` job, that keeps this resource as up-to-date as possible.

PBS Cloud needs two custom server-level consumable integer resources to represent each kind of application license.

- A dynamic resource updated by a server_dyn_res script: The scheduler uses the dynamic resource to check license availability for jobs. The scheduler needs to use a dynamic resource because it needs the resource to be up-to-date for each scheduling cycle.
- A static resource updated via a `cron` script: The cloud bursting hooks use the static resource to check license availability for jobs. The cloud bursting hooks cannot use the dynamic resource because that resource is not available to the hooks.

3.2.4.1 Create cron Script and Static Resource

1. For each kind of application license, create one custom server-level static consumable long resource. The command looks like this:

   ```
   qmgr -c 'create resource <application license static resource> type=long,flag=q'
   ```

2. Create a `cron` script that updates the value of each static consumable license-tracking resource. Currently the simulator needs the value of the static resource to include the number of licenses being used. We recommend that the `cron` script should do the following:

   a. Duplicate the code in the server_dyn_res script to retrieve the number of free licenses

   b. Add the number of licenses being used; this is the value in the server's resources_assigned.<static resource>

   c. Update the server's resources_available.<static resource> value by calling `qmgr`:

      ```
      qmgr -c 'set server resources_available.<static resource>=<updated value>'
      ```

3. The script has to run as manager or root. If you run it as manager, add the script owner to the server's list of managers:

   ```
   qmgr -c 'set server managers += <script owner>'
   ```

4. Set the permissions of the script to *0700*.

5. The script should run at least as frequently as the cloud bursting hooks. The script does not need to run more than twice as often as the cloud bursting hooks.

If you have any questions, contact Altair support; we will be happy to work with you.

3.2.4.2 Create Dynamic Server-level Resource for Each Application License

If you have already created a dynamic server-level resource for each application license, and it is already updated via a server_dyn_res script, you can skip this step.

1. For each kind of application license, create one custom server-level dynamic long resource. The command looks like this:

   qmgr -c 'create resource <application license dynamic resource> type=long'

2. Write a server_dyn_res script that returns the number of available licenses via stdout.

   The format of a dynamic server-level resource query is a shell escape:

   server_dyn_res: "<resource name> !<path to command>"

   In this query, *<resource name>* is the name of the dynamic resource, and *<path to command>* is typically the full path to the script or program that performs the query in order to determine the status and/or availability of the new resource you have added. This usually means querying a license server.

3. Name the script to indicate what it does, for example, "serverdyn.pl".

4. Place the script on the server host. For example, it could be placed in /usr/local/bin/serverdyn.pl

5. Make sure the server_dyn_res script meets the following requirements:

   - The script:
     - Owned by PBS_DAEMON_SERVICE_USER
     - Has permissions of 0755
     - Returns its output via stdout, and the output must be in a single line ending with a newline
     - The scheduler has access to the script, and can run it
     - If you have set up peer scheduling, make sure that the script is available to any scheduler that needs to run it
   - The directory containing the script:
     - Owned by PBS_DAEMON_SERVICE_USER
     - Accessible only by PBS_DAEMON_SERVICE_USER (must not give write permission to *group* or *others*)
     - Has permissions 0550

6. Configure each scheduler to use the server_dyn_res script by adding the resource and the path to the script in the server_dyn_res line of <sched_priv directory>/sched_config. For example:

   ```
   server_dyn_res: "floatlicense !/usr/local/bin/serverdyn.pl"
   ```

7. Optionally give each scheduler a time limit for the script by setting its server_dyn_res_alarm attribute:

   qmgr -c 'set sched <scheduler name> server_dyn_res_alarm=<new value>'

8. For each application license, add both its static and dynamic custom resources (the one tracked by the server_dyn_res script, **and** the one tracked by the cron job) to the resources: line in <sched_priv directory>/sched_config. For example, if your resources that track App1 are app1_static and app1_dyn:

   ```
   resources: "ncpus, mem, arch, host, vnode, netwins, aoe, cloud_scenario, cloud_node_image,
       cloud_node_instance_type, app1_static, app1_dyn"
   ```

9. Restart each scheduler. See "Restarting and Reinitializing Scheduler or Multisched" on page 148 in the PBS Professional Installation & Upgrade Guide.

3.2.4.3 Include Licenses in Scenarios

Later, when you define each scenario that uses licenses, you will follow the instructions in section 4.2.4.3, “Steps to Define a Scenario in a Hook Configuration File”, on page 59 to set the value for check_resources. You do not need to do this now; the instructions are included in the steps for defining a scenario.

3.2.5 Create and Configure Cloud Queues

Create one cloud queue for each scenario. We show the relationships between a cloud queue, a scenario definition in the PBS Cloud interface, and a hook configuration file in section 3.1.1, “Overview of Creating Bursting Scenarios”, on page 22.

1. Log in to the PBS server host as root
2. Create a queue. You may find it helpful to name each cloud queue with information that makes it easy to match the queue with its purpose and/or scenario:

   ```
   qmgr -c "create queue <queue name> queue_type=execution,enabled=true,started=true"
   ```

3. Make this queue into a cloud queue:

   ```
   qmgr -c "set queue <queue name> resources_available.cloud_queue = True"
   ```

4. Assign a bursting scenario to the queue:

   ```
   qmgr -c "set queue <queue name> resources_available.cloud_scenario = <scenario name>"
   ```

   The queue scenario name must be identical to the scenario name in the cloud bursting hook configuration file. Here is an example scenario named "azure_scenario_1" as it would appear in the cloud bursting hook configuration file:

   ```
   "scenario": {
       "azure_scenario_1": {
           "api_key": "<API key>",
           "cloud_default_image": "azure_bursting_image1",
           "cloud_max_instances": 10,
           "network_max_group_size" : 10,
           "network_type": "new",
           "max_nodes_per_burst":50,
           "cloud_node_wait_timeout":180,
           "check_resources":["hw_units"],
           "preemptable": false
       }
   }
   ```

   See Chapter 4, "Configuring the Cloud Bursting Hook", on page 53.

5. Assign a default instance type to the queue:

   ```
   qmgr -c "set queue <queue name> resources_available.cloud_instance_type = <instance type>"
   ```

   This is the default instance type to be burst for this queue. It must match one of the instance types enabled for the bursting scenario that you assigned to the queue. For example:

   ```
   qmgr -c "set queue <queue name> resources_available.cloud_instance_type = Standard_DS2_v2"
   ```

   See section 3.3.4.7.i, “Cloud Provider Instance Types”, on page 43.

6. Set the cloud_account resource for this queue to the cloud account associated with the queue. To find cloud account names, see section 7.2.1, "Viewing Cloud Account Details", on page 163. Use the exact string that you gave to PBS Cloud:

   ```
   qmgr -c 'set queue <queue name> cloud_account=<account name>'
   ```

7. Make each job chunk inherit the default instance type, if the job does not request it explicitly:

   ```
   qmgr -c "set queue <queue name> default_chunk.cloud_node_instance_type = <instance type>"
   ```

   This is the same default instance type you assigned to resources_available.cloud_instance_type for this queue. For example:

   ```
   qmgr -c "set queue <queue name> default_chunk.cloud_node_instance_type = Standard_DS2_v2"
   ```

8. Make each job chunk inherit the default OS image for the scenario, if the job does not request it explicitly. Set the default chunk for the queue to the default image. This is the same as the OS image specified in the cloud_default_image scenario parameter:

   ```
   qmgr -c "set queue <queue name> default_chunk.cloud_node_image = <default OS image>"
   ```

9. Make each job chunk inherit the scenario for this queue. Set the default chunk for the queue to the same scenario specified in resources_available.cloud_scenario for the queue:

   ```
   qmgr -c "set queue <queue name> default_chunk.cloud_scenario = <name of scenario in
       resources_available.cloud_scenario>"
   ```

10. For each cloud queue, verify that the value of resources_default.node_location is unset. List the queue:

    To list a specific queue:

    ```
    qmgr -c 'list queue <queue name>'
    ```

    To list all queues:

    ```
    qmgr -c 'list queue'
    ```

3.2.6 Configure Non-cloud Queues and Nodes

Here we describe the basic configuration for PBS Cloud, where jobs in cloud queues run only on cloud nodes, and jobs in non-cloud queues run only on premises.

- Make sure that each non-cloud queue is marked as a non-cloud queue, so that the cloud bursting hooks do not analyze the jobs in non-cloud queues. At each non-cloud queue, the value of resources_available.cloud_queue should be *False*:

  ```
  qmgr -c "set node <vnode name> resources_available.cloud_queue=false"
  ```

- Make sure that jobs do not span both on-premise and cloud nodes. Set the node_location resource to indicate that these queues and nodes are on premises. You can use a value such as "*local*" or "*on-prem*"; use the same value everywhere on premises:
  - At each non-cloud queue, set the default_chunk.node_location queue resource to "*local*", "*on-prem*", or similar

    ```
    qmgr -c "set queue <queue name> default_chunk.node_location=on-prem"
    ```

  - At each on-premise node, set resources_available.node_location to "*local*", "*on-prem*", or similar:

    ```
    qmgr -c "set node <vnode name> resources_available.node_location=on-prem"
    ```

  - In the sched_config file, add node_location to the "resources:" line

We describe the additional configuration to allow more flexibility in section 3.2.8, "Running Cloud Queue Jobs On Premises", on page 31 and section 3.2.9, "Running Non-Cloud Queue Jobs in the Cloud", on page 31.

3.2.7 Use Authentication and Encryption

We recommend configuring PBS Professional so that it uses authentication and encryption when communicating with cloud nodes (as well as other nodes).

- Configure PBS to use authentication via MUNGE; see "Authentication for Daemons & Users" on page 508 in the PBS Professional Administrator's Guide.
- Configure PBS to use encrypted communication via TLS; see "Encrypting PBS Communication" on page 517 in the PBS Professional Administrator's Guide.

3.2.8 Running Cloud Queue Jobs On Premises

To allow jobs in a cloud queue to run on premises, set the host-level cloud resources at on premise nodes to the specific combination of scenario, OS image, and instance type that you want to run on premises. You can set each on premise node with one scenario, one OS image, and one instance type. This way the scheduler can run jobs requiring those specific resources on premises when the on premise resources are available, and when they are not, the cloud bursting hook will burst the required cloud nodes:

```
qmgr -c "set node <vnode name> resources_available.cloud_node_image=<OS image>"
qmgr -c "set node <vnode name> resources_available.cloud_node_instance_type=<instance type>"
qmgr -c "set node <vnode name> resources_available.cloud_scenario=<scenario name>"
```

To set multiple nodes, you can use the `active` command with `qmgr`:

```
qmgr <return>
Qmgr: active node <node1>,<node2>,...<nodeN>
Qmgr: set node resources_available.cloud_node_image=<OS image>"
Qmgr: set node resources_available.cloud_node_instance_type=<instance type>"
Qmgr: set node resources_available.cloud_scenario=<scenario name>"
```

3.2.9 Running Non-Cloud Queue Jobs in the Cloud

To allow jobs in non-cloud queues to run on cloud nodes, you can use a periodic hook that examines the jobs in one or more non-cloud queues and moves selected jobs to selected cloud queues. For example, you may want to make sure that jobs don't wait longer than a specific amount of time before they run.

You can manage which jobs in non-cloud queues are selected to be run on cloud nodes. If for example job submitters want to minimize cost by keeping their jobs on premises regardless of wait time, you can create a job-wide resource such as "prem-only" that job submitters can request; the hook can ignore jobs that request this resource. Or you can designate specific non-cloud queues for jobs that are allowed or not allowed to run on cloud nodes.

3.3 Configuring PBS Cloud

3.3.1 Log Into PBS Cloud

You must be logged into PBS Cloud as pbsadmin@altair to configure PBS Cloud.

Log into PBS Cloud from your web browser:

```
http://<PBS Cloud host name or IP address>:<port>/pbspro-cloud/#/login
```

- Default port: 9980
- Username: pbsadmin@altair
- Password: <administrator password> (Default is *Altair@123*)

We recommend changing the password immediately; use the UX to do this; see section 7.5, “Updating PBS Cloud Administrator Password”, on page 167.

3.3.2 Create Your Cloud Provider Account

PBS Cloud uses an administrator account at the cloud provider to manage cloud nodes. Create your cloud provider account; follow the steps for your cloud provider in Chapter 5, "Using Cloud Provider Services", on page 67. While you are creating the account, capture the information we list at the start of the provider-specific instructions; you will use that information to add your cloud provider account to PBS Cloud.

3.3.3 Add Your Provider Account to PBS Cloud

PBS Cloud can use multiple cloud providers, and can use multiple accounts at each provider.

Tell PBS Cloud about the cloud account you have created at your cloud provider by filling in the PBS Cloud parameters. We will walk you through the steps.

The Name parameter is common to all accounts, meaning that all accounts have a name, but the name can be different for each provider. The other parameters for an account are different for each vendor; for example, only Oracle uses a fingerprint ID. Follow the steps for your vendor to capture the information we list so that you can use it to fill in the account parameters. For the vendor-specific steps, see Chapter 5, "Using Cloud Provider Services", on page 67.

The information required varies by cloud provider.

1. Click the Cloud tab.
2. Under Infrastructure, click Cloud.
3. Select your cloud provider
4. Fill in the account name. This is an arbitrary string, and it is not the administrator account name created at the vendor. We recommend making it informative.

5. Add the information for the parameters that are vendor-specific. We list the parameter information by vendor:

   - For an Amazon Web Services (AWS) account:

Table 3-1: Account Parameters for Amazon Web Services (AWS)

Account Parameter	Collected During Configuration at Vendor	Format
Access Key ID	Access Key ID from vendor `.csv` file	String
Secret Access Key	Secret Access Key from vendor `.csv` file	String

   - For an Azure account:

Table 3-2: Account Parameters for Microsoft Azure

Account Parameter	Collected During Configuration at Vendor	Format
Client ID	Application ID generated when registering PBS Cloud with the Azure Active Directory	String
Secret Key	Secret Key generated during account creation at vendor	String
AD Tenant ID	Azure tenant ID generated during account creation at vendor	String
Subscription ID	Subscription ID generated during account creation at vendor	String

   - For a Google Cloud Platform (GCP) account:

Table 3-3: Account Parameters for Google Cloud Platform (GCP)

Account Parameter	Collected During Configuration at Vendor	Format
Project ID	Value of project_id in JSON file created at vendor	String
Client ID	Value of client_id in JSON file created at vendor	String
Client Mail	Value of client_email in JSON file created at vendor	String
Private Key ID	Value of private_key_id in JSON file created at vendor	String
Private Key	Value of private_key in JSON file created at vendor	String

   - For an Oracle account:

Table 3-4: Account Parameters for Oracle

Account Parameter	Collected During Configuration at Vendor	Format
User OCID	User OCID generated when creating Oracle cloud user account at vendor	String
Tenant OCID	Tenancy OCID generated at vendor	String

Table 3-4: Account Parameters for Oracle

Account Parameter	Collected During Configuration at Vendor	Format
Compartment OCID	Root compartment OCID generated at vendor	String
Fingerprint OCID	Fingerprint generated when adding the public SSH key for Oracle user at vendor	String
Private Key	RSA private key generated at vendor	String

- For a Huawei, Deutsche Telekom, Orange, or OpenStack account:

Table 3-5: Account Parameters for Huawei, Deutsche Telekom, Orange, OpenStack

Account Parameter	Collected During Configuration at Vendor	Format
Auth URL	Orange: *https://iam.<orange region>.<console link>* Huawei: *https://iam.ap-southeast-1.myhwclouds.com* Deutsche Telekom: *https://iam.eu-de.otc.t-systems.com/v3* OpenStack: contact Altair support	String
User Domain Name	Orange: Customer ID used to log in to Orange account. Same as domain name Deutsche Telekom: OTC domain name used to log in to OTC console at vendor Huawei: Domain Name provided when your subscription to HUAWEI Cloud was created OpenStack: Domain name for cloud account in private cloud	String
Username	Administrator username created at vendor	String
Password	Huawei & Deutsche Telekom: Administrator password created at vendor Orange: API password generated at vendor OpenStack: Password for administrator account	String

- For an Alibaba Cloud account:

Table 3-6: Account Parameters for Alibaba Cloud Account

Account Parameter	Collected During Configuration at Vendor	Format
Access Key ID	Access Key ID from vendor `.csv` file	String
Access Secret Key	Access Secret Key from vendor `.csv` file	String

6. Click Create account.

3.3.3.1 Example of Adding Azure Account to PBS Cloud

1. Log in to PBS Cloud.
2. Click the Cloud tab.
3. Under Infrastructure, click Cloud.
4. Click 

5. Enter the following to add a cloud account:
   a. For Account name, enter any name for the cloud account.
      The name can be anything meaningful to your organization, e.g., azure_cloudaccount.
   b. For Client ID, enter the Application ID generated when PBS Cloud was registered with the Azure Active Directory.
   c. For Secret Key, enter the client secret key generated when you register PBS Cloud.
   d. For AD tenant ID, enter your Azure tenant ID.
   e. For Subscription ID, enter your Azure subscription ID.
6. Click Create account.

3.3.4 Create a Bursting Scenario

A bursting scenario encapsulates information needed to burst cloud nodes. Some scenario parameters are common to all scenarios, meaning that all scenarios have an associated hostname prefix, but the hostname prefix can be different for each scenario. Some parameters for a bursting scenario are different for each vendor; for example, only Azure uses a resource group. For each vendor, we list the steps to capture required scenario information, so that you can use it to fill in the scenario parameters in the PBS Cloud interface. For the vendor-specific steps, see Chapter 5, "Using Cloud Provider Services", on page 67.

You can create an unlimited number of bursting scenarios. We recommend creating and testing them one at a time.

1. Go to the bursting scenario interface in PBS Cloud:
   a. Open a browser window and log in to PBS Cloud.
   b. Click on Cloud.
   c. Under Infrastructure, click on Bursting.
   d. Click Add Bursting Scenario.
2. Add the information for the following parameters common to all scenarios:

Table 3-7: Common Scenario Parameters

Scenario Parameter	Description	Format
Name	Arbitrary friendly scenario name	String
Description	Arbitrary scenario description	String
Cloud account	Name of your account at cloud vendor	String
Region	Region selected during configuration at cloud vendor	Drop-down list

Table 3-7: Common Scenario Parameters

Scenario Parameter	Description	Format
Domain name	Domain used by cloud nodes to talk to PBS server	String
Hostname prefix	Optional prefix for burst node names; default is "node"; chosen during configuration at vendor; see section 3.3.4.1, “Adding Hostname Prefix”, on page 40	String
Add public IP to VMs	Optional public IP address to VMs for initial troubleshooting; see section 3.3.4.2, “Temporarily Adding Public IP for Debugging”, on page 40	Checkbox
cloud-init	Name of startup script launched by `cloud-init` for configuring freshly burst nodes. Browse to a file, and optionally edit the file; see section 3.3.4.3, “Specifying the Cloud Node Startup Script”, on page 40	String
SSH keys	Administrator SSH key to give you access for initial debugging if `/home` won't mount in the node; see section 3.3.4.4, “Adding SSH Key for Access to Burst Nodes”, on page 41	String
Idle time before unbursting	Time for burst node to sit idle before unbursting. Default: 180 seconds; see section 3.3.4.5, “Setting Idle Time”, on page 41	Integer seconds
Tag	Optional labeling system for convenience. You can apply multiple tags. See section 3.3.4.6, “Adding Tags (Labels) to Scenario”, on page 42	Key:value pair as *<string>:<string>*
Instances	Instances that will be available for job submitters to select for their jobs. Instances must be all non-preemptable or all preemptable, and all bare-metal or non-bare-metal; see section 3.3.4.7, “Managing Instances”, on page 42	Checkboxes

3. Add the information for the parameters that are vendor-specific:

   - For an AWS scenario:

Table 3-8: Scenario Parameters for Amazon Web Services (AWS)

Scenario Parameter	Collected During Configuration at Vendor	Format
AMI ID	Name of image to be burst; chosen during configuration at vendor	String
Security Group IDs	List of security group IDs associated with VPC and VM created at vendor	Comma separated strings
Subnet ID	Name of security group subnet for bursting VPC created at vendor. To burst nodes in multiple Availability Zones, use a comma-separated list of subnet IDs	String

   - For a GCP scenario:

Table 3-9: Scenario Parameters for Google Cloud Platform (GCP)

Scenario Parameter	Collected During Configuration at Vendor	Format
Network name	Name of VPC for cloud bursting created at vendor	String
Subnetwork name	Name of VPC network subnet created at vendor	String
OS Image URI	Choose image, click "REST Equivalent", find value of "selfLink" name-value pair, and put it here (This gives path to the OS image)	String

   - For an Azure scenario:

Table 3-10: Scenario Parameters for Microsoft Azure

Scenario Parameter	Collected During Configuration at Vendor	Format
Resource group name	Name of resource group (virtual network, virtual machine, OS image) created at vendor	String
Network name	Name of virtual network created at vendor If the network is in a different resource group from the one specified, enter it as Resource Group Name/Virtual Network Name	String
Subnetwork name	Name of virtual subnet created at vendor If the subnet is in a different resource group from the one specified, enter it as Resource Group Name/Subnet Name	String

Table 3-10: Scenario Parameters for Microsoft Azure

Scenario Parameter	Collected During Configuration at Vendor	Format
Network security group name	Name of network security group for resource group If the network security group is contained in a resource group that is different from the one entered for the bursting scenario, enter it as Resource Group Name/Network Security Group Name.	String
Managed Storage	Managed disk feature selected at vendor	Boolean
OS Image	If using managed disks, name of the image. If not using managed disks, Linux Source BLOB URI. If the OS image is contained in a Resource group that is different from the one entered for the bursting scenario, enter it as Resource Group Name/OS Image Name or Resource Group Name/URI.	String
Maximum number of VMs inside a ScaleSet with Managed Storage and a single Placement Group	Set this to the maximum number of maximum number of VMs you want allowed in a scale set. If you use InfiniBand, the default limit available is 100. This limit is set by vendor; can be negotiated. Without InfiniBand, for a scale set with managed disk and custom image, you can specify a higher limit. Make sure this conforms with what the vendor can provide.	Integer

- For an Oracle scenario:

Table 3-11: Scenario Parameters for Oracle

Scenario Parameter	Collected During Configuration at Vendor	Format
Subnet ID	OCID of subnet associated with data center where cloud bursting virtual machine is hosted	String
OS Image URI	Vendor link to bursting image OCID	String

- For a Huawei, Deutsche Telekom, Orange, or OpenStack scenario:

Table 3-12: Scenario Parameters for Huawei, Deutsche Telekom, Orange, OpenStack

Scenario Parameter	Collected During Configuration at Vendor	Format
Subnet ID	ID of subnet for VPC created at cloud vendor	String
Security Group ID	ID of security group created at cloud vendor	String
OS Image URI	ID of OS image created at cloud vendor	String

- For an Alibaba Cloud scenario:

Table 3-13: Scenario Parameters for Alibaba Cloud

Scenario Parameter	Collected During Configuration at Vendor	Format
Zone	Zone selected during VPC creation. Use the exact string listed in the Regions and Zones list	String
VPC ID	ID of VPC you created	String
vSwitch ID	ID of vSwitch you created	String
Image ID	ID of custom image you created at cloud vendor	String
Security Group ID	Security group ID associated with VPC and VM you created at vendor	String

4. Create the scenario: click on "Instantiate scenario"
5. Create an API key and add it to the scenario (PBS Cloud keeps it, but hidden; after this, you can never see it again).

   Each cloud hook uses the scenario API key as a unique identifier for that scenario. You cannot use the same API key for more than one scenario. If you lose an API key, you can generate a new one. Later, you will put this API key in the appropriate cloud bursting hook configuration file so that the hook can identify the correct scenario.

   The default lifetime of an API key is one year. You can have multiple keys for a scenario; this is to allow overlap near the expiration date. You can only list one API key per scenario in a cloud hook configuration file.

   You can create an API key only for an existing scenario.

Generate and save the key using the following steps:

a. Click *Add token* located at the bottom of the web page to open up a dialog box.

b. For Name, enter a name for the API key. Format: lowercase alphabetic + numeric

c. For Expiration date, specify the expiration date. Format: MM/DD/YYYY

d. Generate the API key by clicking *Add Token* inside the dialog box.

PBS Cloud generates the API key, and displays it only once.

e. **Copy and save the API key** so that you can paste it into the appropriate cloud hook configuration file later.

f. Click Close.

6. We recommend adding quotas on resource usage, and alerts when those quotas are reached. To set each quota and associated alert:

a. Click Add Quota.

b. For Resource, choose a resource from the menu.

c. Click Add Quota.

d. For Limit, provide a limit for the resource.

e. To add an alert for this quota, click Add.

f. Provide an alert value.

For more about quotas and alerts, see section 3.3.4.8, “Adding Quotas and Alerts”, on page 43.

7. Enable the scenario; see section 7.2.4, “Enabling or Disabling a Bursting Scenario in PBS Cloud”, on page 164.

3.3.4.1 Adding Hostname Prefix

The hostname prefix is the base name of each burst node. For example, if you choose "cloudnode", burst nodes are named "cloudnode1", "cloudnode2", "cloudnode3", etc. Format is a string.

3.3.4.2 Temporarily Adding Public IP for Debugging

You can add a public IP address to the bursting scenario to make it easier to debug, then remove the IP address when you have your scenario working. To add a public IP address to the scenario:

1. Log in to PBS Cloud.
2. Click on Cloud.
3. Under Infrastructure, click on Bursting.
4. Click the name of the bursting scenario.
5. Click on the Customization tab
6. Click Edit
7. Check the checkbox next to Enable Public IP Address.
8. Click Save.

3.3.4.3 Specifying the Cloud Node Startup Script

You can optionally use the `cloud-init` tool to run a cloud node startup script when each node is burst, to automate node configuration tasks. We describe how to create the script in Chapter 6, "The Cloud Node Startup Script", on page 155. The startup script can be located anywhere that your PBS Cloud web interface can browse to. Once a script has been added to a scenario, the script is stored in the PBS Cloud database.

Note that you may not need a startup script. If you configure the VM that you use to create your OS image to have everything you need to run jobs, you do not need a startup script.

3.3.4.3.i Startup Script Prerequisites

- The startup script must run using a shell or language available in the freshly burst node. For example, if you have `bash` and Python available, your script can use `bash`, or it could use a `bash` script to launch a Python script.
- On Windows cloud nodes, use a PowerShell startup script. Enclose the content of the PowerShell script in <powershell> and </powershell>. Refer to Microsoft documentation for more information about PowerShell.
- The startup script can have any name.

3.3.4.3.ii Steps to Add Startup Script to Scenario

You can add and edit the cloud node startup script for this scenario from the web interface:

1. Log in to PBS Cloud.
2. Click Cloud.
3. Under Infrastructure, click Bursting.
4. Click the name of the bursting scenario.
5. Click the edit pen.
6. Click the Browse button, and browse to the file you want
7. Optionally edit the file as needed
8. Click Save.

3.3.4.4 Adding SSH Key for Access to Burst Nodes

You typically add the administrator SSH key so that if `/home` fails to mount during node bursting while testing a scenario, you can log in and debug the problem. For example, you need an SSH key when `yum update` turns SELinux back on and `/home` won't mount. Public SSH keys in a scenario are copied to each burst node for secure connectivity.

You can add SSH keys for only those users allowed to submit jobs to these burst nodes, although you have to make those users' home directories available on the burst nodes so that PBS Professional can use them for jobs.

To add a public SSH key for access to burst nodes:

1. Log in to the PBS Professional server host.
2. Copy the public SSH key for the user; public key files are usually stored in `/.ssh` in the user's home directory.
3. In the PBS Cloud interface:
   a. Click Add; PBS Cloud displays an editable box
   b. In Public SSH keys, paste the public SSH key.

To remove public SSH keys so that users do not have access to burst nodes, click the "x" located next to the SSH key box.

3.3.4.5 Setting Idle Time

The Idle before unburst parameter specifies the minimum time that a cloud node can be idle before it is unburst.

Default idle time is 180 seconds. We recommend making the idle time more than double the PBS scheduler cycle time.

Format is integer seconds.

3.3.4.6 Adding Tags (Labels) to Scenario

You can optionally add tags (labels) to burst nodes in order to categorize them, for example by purpose, owner, or environment. You can add multiple tags.

1. Log in to PBS Cloud.
2. Click Cloud.
3. Under Infrastructure, click Bursting.
4. Click the name of the bursting scenario.
5. Click the Cloud tab, then the global edit pen.
6. The Tags box appears.
1. To add a label to that will be applied to burst nodes, enter a key-value pair, followed by <return>. Format:

   <key>:<value><return>

   The key and the value can contain alphanumeric, dash (-) and an underscore (_). The maximum length for the key is 35 characters, and the maximum length for the value is 42 characters.

   The <return> is required.

   When you add the tag, it appears within its own bubble:

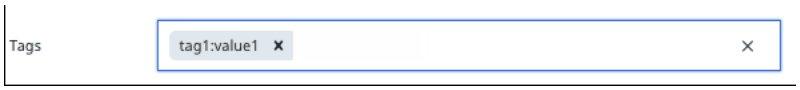

Figure 3-2:Key-Value Tag

   Repeat the previous step to add more tags:

Figure 3-3:Additional Tags

2. Click Save.

3.3.4.7 Managing Instances

When you create a scenario, choose the instance types that you want job submitters to be able to use with that scenario. The instance type determines which hardware is used to burst the cloud node. The available instance types depend on which cloud provider you use.

For each scenario, you can use either all non-preemptable instance types, or all preemptable instance types. Do not mix the two. See section 3.3.5, “Using Spot or Preemptable Pricing”, on page 46. For information about spot and preemptable instance types, see section 3.3.5, “Using Spot or Preemptable Pricing”, on page 46.

For each scenario, you can use either all bare-metal or all non-bare-metal instance types, but not both.

3.3.4.7.i Cloud Provider Instance Types

The instance type (also called shape, machine type or flavor) determines the hardware of the host computer used for your cloud nodes. Each instance type offers different compute, memory, and storage capabilities. The following table lists some instance types by cloud provider:

Table 3-14: Some Example Instance Types

Provider	Classification System	Example Instance Types
Azure	Instance sizes	Standard_DS1_v2, Standard_D2s_v3, Standard_NC6 Standard_H16r, Standard_H16mr (InfiniBand)
AWS	Amazon EC2 instance types	t2.medium, r4.large, p3.2xlarge
GCP	Machine types	n1-standard-8, n1-highmem-2, n1-highcpu-64
Oracle	Machine shapes and GPU instances	VM.Standard1.1, VM.DenseIO1.16, VM.GPU3.1
Orange Cloud	Instance family	s1.medium, s3.large.4, cc3.large.4
HUAWEI Cloud	ECS types	s2.small.1, s2.medium.4, s2.xlarge.2
OTC	ECS types	s1.medium, c1.large, m1.xlarge

3.3.4.7.ii Steps to Choose Instance Types

1. Log in to to PBS Cloud.
2. Click Cloud.
3. Under Infrastructure, click Bursting.
4. Click the name of the bursting scenario.
5. Click *Edit Instances*.
6. Choose the instance types you want available for the bursting scenario by clicking the Enabled checkbox located to the far right of the instance type name.
7. Click Save. You will see a list of the enabled instance types.

3.3.4.7.iii Managing Hyperthreading for an Instance Type

You can choose whether or not to enable hyperthreading via a checkbox next to the instance type. By default, PBS cloud enables hyperthreading. The vendor reports hyperthreading to PBS Cloud, and PBS Cloud reports hyperthreading to the cloud bursting hooks.

If you turn off hyperthreading for an instance type, PBS Cloud disables hyperthreading in the cloud node, and reports the the number of available cores to the hooks, so that job requests are aligned with core availability.

If you leave hyperthreading on, hyperthreading is enabled, and PBS Cloud reports the number of threads to the cloud bursting hooks. In this case, job requests are aligned with thread availability.

3.3.4.8 Adding Quotas and Alerts

For each scenario, you can optionally specify quotas on resource usage at any point in time, so that when PBS Cloud hits a quota, it stops bursting nodes until usage drops back down. Use quotas to prevent huge jumps in expenditure.

For each quota, you can set an associated alert so that the web interface displays a notification when the quota is reached.

You can add quotas and alerts only to an existing scenario.

You can set quotas on the following:

- Number of CPUs in use
- Amount of memory in use
- Number of burst nodes

To set each quota and associated alert:

1. Log in to PBS Cloud.
2. Click Cloud.
3. Under Infrastructure, click Bursting.
4. Click the name of the bursting scenario.
5. Click Add Quota.
6. For Resource, choose a resource from the menu.
7. Click Add Quota.
8. For Limit, provide a limit for the resource.
9. To add an alert for this quota, click Add.
10. Provide an alert value.

3.3.4.9 Example of Creating a Scenario

Example 3-1: Create an Azure cloud bursting scenario; see section 5.2.9, “Collect Information for an Azure Cloud Bursting Scenario”, on page 93

We show some recommended options:

- For Name, give the scenario a short name, all in lowercase, e.g. hyperburst
- Select Managed Disks
- For node debugging, select Public IP; you can disable this once your scenario is working properly
- We recommend using the Standard_A4 instance type for minimal cost
- Optionally provide a startup script; for a sample script, see section 6.2.4, “Example cloud-init Startup Script for Linux”, on page 158
- Create an API key and store it safely. It is lost once you close the window, although you can simply create another if you lose it
- Enable the scenario; see section 7.2.4, “Enabling or Disabling a Bursting Scenario in PBS Cloud”, on page 164

3.3.4.10 Editing a Bursting Scenario

You can use the web interface to PBS Cloud to edit a scenario and specify bursting scenario elements, including scenario name, description, domain name, OS image, and VPC details.

1. Before you edit a bursting scenario, stop the bursting process and make sure no jobs are running on the burst nodes; see section 7.2.5, “Disabling Bursting for a Scenario and Queue”, on page 165.
2. Edit the bursting scenario:
   a. Log in to PBS Cloud.
   b. Click Cloud.
   c. Under Infrastructure, click Bursting.
   d. Select the name of the bursting scenario.
   e. To modify the scenario, click the edit pen.

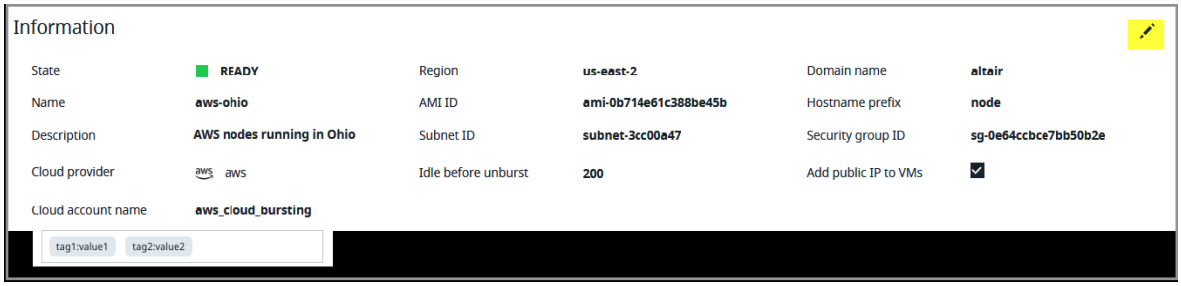

Figure 3-4:Edit Scenario Details

3. After you edit the scenario, enable it; see section 7.2.4, “Enabling or Disabling a Bursting Scenario in PBS Cloud”, on page 164.

3.3.4.11 Creating API Key for Cloud Hook to Use

Each cloud hook uses the scenario API key as a unique identifier for that scenario. You cannot use the same API key for more than one scenario. If you lose an API key, you can generate a new one. Later, you will put this API key in the appropriate cloud bursting hook configuration file so that the hook can identify the correct scenario.

The default lifetime of an API key is one year. You can have multiple keys for a scenario; this is to allow overlap near the expiration date. You can only list one API key per scenario in a cloud hook configuration file.

You can create an API key only for an existing scenario.

Generate and save the key using the following steps:

1. Log in to PBS Cloud.
2. Click Cloud.
3. Under Infrastructure, click Bursting.
4. Click the name of the bursting scenario.
5. Click *Add token* located at the bottom of the web page.
6. For Name, enter a name for the API key. Format: lowercase alphabetic + numeric
7. For Expiration date, specify the expiration date. Format: MM/DD/YYYY
8. Generate the API key by clicking Add Token.

   PBS Cloud generates the API key, and displays it only once.

9. **Copy and save the API key** so that you can paste it into the appropriate cloud hook configuration file later.
10. Click Close.

3.3.5 Using Spot or Preemptable Pricing

3.3.5.1 When to Use Spot or Preemptable Instances

Preemptable instances offer spare compute capacity available in the cloud at steep discounts compared to on-demand instances. Spot instances are preemptable. Drawbacks:

- Spot and preemptable instances can be interrupted with two minutes' notice when the provider needs the capacity back. AWS, Azure, and GCP can preempt your spot instance when the vendor needs the resource.
- AWS and Azure can interrupt your spot instance when the spot price exceeds your maximum price, when the demand for spot instances rises, or when the supply of spot instances decreases.
- Google Cloud Platform (GCP) will kill your instance if it has been running for 24 hours.

We do not recommend running critical or long-running jobs in spot instances, as jobs may be killed when spot instances are preempted.

You can take advantage of preemptable and spot instances by using them for shorter jobs, and jobs that can be preempted.

3.3.5.2 How Spot and Preemptable Instances Work

- Dedicated on-demand: the instance is guaranteed to be available, but does not need longer-term commitments or up-front payments. You can increase or decrease your compute capacity depending on the demands of your application. You pay only for what you use. Fixed per hour or per second price depending on the instance type.
- Preemptable: vendor can preempt instance with about 2 minutes' notice; You pay a fixed discount. Instance is killed after 24 hours. GCP uses this model.
- Spot: price is set by vendor, based on demand. You set the max you are willing to pay. You pay actual spot price. If current price goes over your max price, all your instances are preempted. If the vendor needs them, they are preempted. Cost savings of up to 90%, but most volatile. AWS and Azure use this model.

3.3.5.3 Setting Max for Spot Pricing

For AWS and Azure, you can specify the maximum price that you are willing to pay to continue using a spot instance. Your max spot price should be greater than 0 and less than the current on-demand price.

3.3.5.4 Preemptable Pricing

For GCP, the price for preemptable instances is fixed.

3.3.5.5 Specifying Spot Pricing

The scenario you use for spot pricing must already exist, must contain only preemptable instances, and must have preemptable set to *true* in the main cloud hook configuration file (you cannot have an instance be both spot/preemptable and bare metal).

1. Configure the main cloud bursting hook with a scenario for this instance type. Make sure that the scenario contains only preemptable instance types. Make sure the instance type is preemptable. In the cloud bursting hook, the scenario must include:

   ```
   "preemptable": true
   ```

   See section 4.2.6, “Creating a Scenario for a Preemptable or Spot Instance”, on page 61.

2. Log in to PBS Cloud.
3. Click the Cloud tab.
4. Under Infrastructure, click Bursting.
5. Select a bursting scenario by clicking on its name.
6. Go to the instance table.

   PBS Cloud displays a table of instance types you can enable for spot pricing:

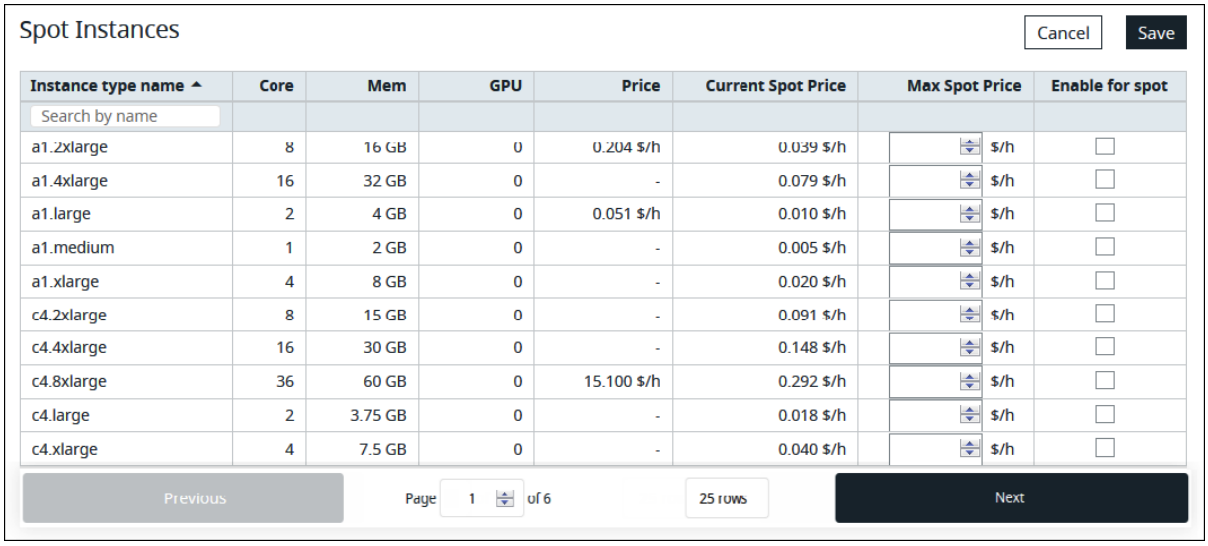

Figure 3-5:Spot Instances

7. Enable spot pricing for an instance type by checking the *Enable for spot* box next to the instance name.
8. For AWS and Azure, set the spot price your site is willing to pay by entering it in the *Max Spot Price* box.
9. Disable spot pricing for an instance type by un-checking the *Enable for spot* box.
10. For AWS and Azure, enter a maximum spot price that you are willing to pay for the instance type.

3.3.5.6 Example of Choosing Instances for Spot Pricing

Two instance types are selected for spot pricing:

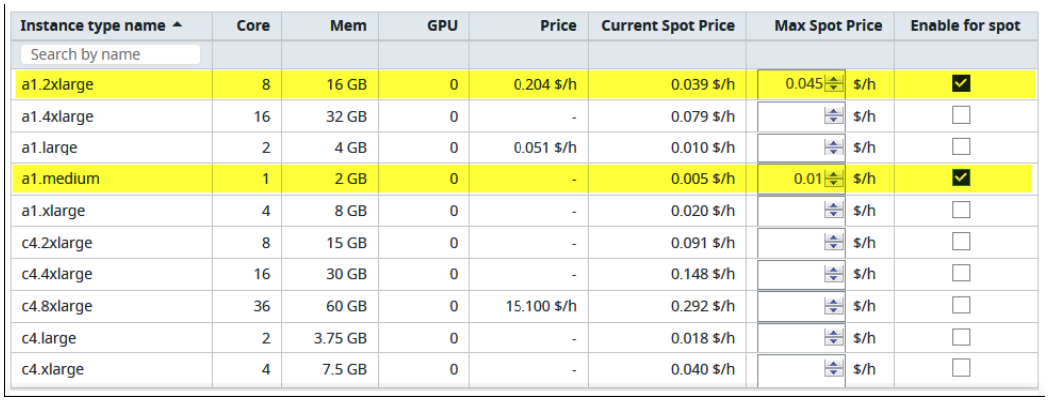

Figure 3-6:Spot Instances

3.3.6 Managing Node Licenses

Make sure that the number of cloud nodes plus the number of on premise nodes does not exceed the number of PBSProNodes licenses for your PBS complex. Set the value of resources_available.cloud_max_instances at the PBS server to be the number of PBSProNodes licenses minus the number of on premise nodes.

3.4 Providing Nodes Grouped on High Speed Network

Job submitters may want to run jobs on cloud nodes where all job nodes are on the same high speed network. Cloud providers can allow PBS Cloud to burst groups of nodes where each group is connected by a high speed switch; in this version these providers are Azure and Oracle, and the high speed network is InfiniBand. Azure provides InfiniBand *scale sets*, and Oracle provides *instance pools*. To simplify the discussion, we call a group of nodes on a high speed network a *proximate node group*.

The main cloud bursting hook handles bursting nodes on high speed networks when the instances are not on bare metal; when instances are on bare metal, that is handled by the extension cloud bursting hook.

When the main cloud bursting hook bursts a group of nodes on a high speed network, the hook labels all of the nodes in that group with the same network name. Job submitters do not need to know or request the actual network name; they only need to request that their job is on such a node group via the `cloud_network=ib` chunk request. The cloud bursting hook automatically creates a placement set for each proximate node group so that the scheduler can run the job within a single node group all on the same high speed network.

3.4.1 Requirements for Providing Nodes on High Speed Networks

To allow jobs to run on groups of nodes on high speed networks:

1. If needed, create a queue for a high speed scenario; see section 3.2.5, “Create and Configure Cloud Queues”, on page 29
2. Configure a high speed scenario using the PBS Cloud interface; see section 3.3.4, “Create a Bursting Scenario”, on page 35
   - No instances in this scenario can be bare metal
   - Make sure that the network_max_group_size scenario parameter conforms to what the vendor can provide
   - Set the network_type scenario parameter to *new*
3. Add the high speed scenario definition to the main cloud bursting hook configuration file
4. Add the API key you created when defining the high speed scenario in the PBS Cloud interface to the "api_key" line in the high speed scenario definition in the main cloud bursting hook configuration file
5. Add an instance type with a high speed network enabled to:
   - The *Instances* section of the high speed scenario definition in the PBS Cloud interface; see section 3.3.4.7, “Managing Instances”, on page 42
   - The high speed queue default_chunk.cloud_node_instance_type
   - The high speed queue resources_available.cloud_instance_type

6. Add an OS image with a high speed network driver to:
   - The "cloud_default_image" line in the high speed scenario definition in the main cloud bursting hook configuration file
   - The high speed queue default_chunk.cloud_node_image
7. Add the high speed scenario to:
   - The configuration file for the main cloud bursting hook; see section 4.2.4, "Defining a Scenario in a Cloud Bursting Hook Configuration File", on page 59
   - The high speed queue resources_available.cloud_scenario
   - The high speed queue default_chunk.cloud_scenario
8. Make sure placement sets use the cloud_network resource and are enabled:

```
qmgr -c "set server node_group_key+=cloud_network"
qmgr -c "set server node_group_enable=true"
```

9. Prevent any single job from running across multiple node groups:

```
qmgr -c "set sched do_not_span_psets=true"
```

10. **Do not** put cloud_network in the `resources:` line in `sched_config`

3.5 Providing Bare-metal Instances

Job submitters may want to run jobs on instances burst on bare metal. Cloud providers can allow PBS Cloud to burst instances on bare metal; in this version the only provider is Oracle, and the high speed network is InfiniBand. Oracle provides groups of bare metal instances in *instance pools*. To simplify the discussion, we call a group of nodes on a high speed network a *proximate node group*.

The extension cloud bursting hook handles bursting nodes on high speed networks when the instances are on bare metal; when instances are not on bare metal, that is handled by the main cloud bursting hook.

When the extension cloud bursting hook bursts a group of instances on bare metal, the hook puts all of the nodes in that group on the same network and labels the nodes with the same network name. Job submitters do not need to know or request the actual network name; they only need to request that their job is on such a node group via the `cloud_network=ib` chunk request. The cloud bursting hook automatically creates a placement set for each proximate node group so that the scheduler can run the job within a single node group all on the same high speed network.

3.5.1 Requirements for Providing Bare Metal Instances

To allow job submitters to request cloud nodes burst on bare metal:

1. Create a cloud queue for the bare metal scenario; see section 3.2.5, "Create and Configure Cloud Queues", on page 29
2. Create the extension cloud bursting hook; see section 2.5, "Create Extension Cloud Bursting Hook", on page 19
3. Create the configuration file for the extension cloud bursting hook; see section 4.2, "Configuring the Cloud Bursting Hooks", on page 55
4. Add the bare metal scenario definition to the extension cloud bursting hook configuration file

5. Configure a bare metal scenario using the PBS Cloud interface; see section 3.3.4, “Create a Bursting Scenario”, on page 35
   - All instances in this scenario must be bare metal
   - Make sure that the network_max_group_size scenario parameter conforms to what the vendor can provide
   - Set the network_type scenario parameter to *new*
6. Add the API key you created when defining the bare scenario in the PBS Cloud interface to the "api_key" line in the bare metal scenario definition in the extension cloud bursting hook configuration file
7. Add an instance type for bare metal with a high speed network enabled to:
   - The *Instances* section of the bare metal scenario definition in the PBS Cloud interface; see section 3.3.4.7, “Managing Instances”, on page 42
   - The bare metal queue default_chunk.cloud_node_instance_type
   - The bare metal queue resources_available.cloud_instance_type
8. Add an OS image for bare metal with a high speed network driver to:
   - The "cloud_default_image" line in the bare metal scenario definition in the extension cloud bursting hook configuration file
   - The bare metal queue default_chunk.cloud_node_image

   You create this OS image, possibly using a base image provided by the cloud vendor. Follow the vendor instructions for creating the OS image.
9. Add the bare metal scenario to:
   - The configuration file for the extension cloud bursting hook; see section 4.2.4, “Defining a Scenario in a Cloud Bursting Hook Configuration File”, on page 59
   - The bare metal queue resources_available.cloud_scenario
   - The bare metal queue default_chunk.cloud_scenario
10. Make sure placement sets use the cloud_network resource and are enabled:

```
qmgr -c "set server node_group_key+=cloud_network"
qmgr -c "set server node_group_enable=true"
```

11. Prevent any single job from running across multiple node groups:

```
qmgr -c "set sched do_not_span_psets=true"
```

12. **Do not** put cloud_network in the `resources:` line in `sched_config`
13. At this point, InfiniBand is not configured. Use `cloud-init` to set up InfiniBand to configure and start the InfiniBand adapter. We show an example of a section of `cloud-init` for managing an OCI BM InfiniBand adapter via its configuration file, where the network adapter is named "enp94s0f0". For a different instance type, the network adapter will be different; check with your cloud provider.

    In this example the node is configured with its main network adapter on 10.30.0.x, and we have configured a network in OCI for 10.40.0.x. Because there is no DHCP on the 10.40 network segment, and the InfiniBand isn't hooked up to any DHCP, we chop out the x from the 10.30.0 network and apply it in the 10.40.0 network. This uses DHCP on the first network to avoid IP duplication on the second network.

All other parts are using the default options for these adapters on BM.HPC2.36 instances. The name of the adapter and required options may vary on different base BM instance types.

```
IPext=$(echo $IP | awk -F. '{print $NF}')
ifdown enp94s0f0
echo "TYPE=\"Ethernet\"" > /etc/sysconfig/network-scripts/ifcfg-enp94s0f0
echo "BOOTPROTO=\"none\"" >> /etc/sysconfig/network-scripts/ifcfg-enp94s0f0
echo "IPADDR=10.40.0.$IPext" >> /etc/sysconfig/network-scripts/ifcfg-enp94s0f0
echo "NETMASK=255.255.255.0" >> /etc/sysconfig/network-scripts/ifcfg-enp94s0f0
echo "DEFROUTE=\"no\"" >> /etc/sysconfig/network-scripts/ifcfg-enp94s0f0
echo "PEERDNS=\"no\"" >> /etc/sysconfig/network-scripts/ifcfg-enp94s0f0
echo "PEERROUTES=\"no\"" >> /etc/sysconfig/network-scripts/ifcfg-enp94s0f0
echo "IPV4_FAILURE_FATAL=\"no\"" >> /etc/sysconfig/network-scripts/ifcfg-enp94s0f0
echo "IPV6INIT=\"no\"" >> /etc/sysconfig/network-scripts/ifcfg-enp94s0f0
echo "IPV6_FAILURE_FATAL=\"no\"" >> /etc/sysconfig/network-scripts/ifcfg-enp94s0f0
echo "NAME=\"System enp94s0f0\"" >> /etc/sysconfig/network-scripts/ifcfg-enp94s0f0
echo "DEVICE=\"enp94s0f0\"" >> /etc/sysconfig/network-scripts/ifcfg-enp94s0f0
echo "ONBOOT=\"yes\"" >> /etc/sysconfig/network-scripts/ifcfg-enp94s0f0
ifup enp94s0f0
```

3.6 Testing Cloud Bursting

We recommend testing each scenario before using it in the cloud bursting hook. After you can manually burst a working cloud node for a scenario, add the scenario to the relevant cloud bursting hook and test that the hook can run jobs on the cloud nodes.

3.6.1 Test Each Scenario using Manual Bursting

3.6.1.1 Troubleshooting Prerequisites

To be able to troubleshoot cloud nodes, make sure the scenario has the following:

- The Add Public IP to VMs scenario option is enabled; see section 3.3.4.2, “Temporarily Adding Public IP for Debugging”, on page 40
- The SSH keys parameter has an administrator SSH key; see section 3.3.4.4, “Adding SSH Key for Access to Burst Nodes”, on page 41
- You have the corresponding private key
- Port 22 in the vendor firewall has to be open (already covered when you were configuring vendor components)

3.6.1.2 Testing and Refining a Scenario

Manually burst a single cloud node for that scenario and test its initial configuration, by following the steps in section 6.3, “Developing the Startup Script”, on page 159.

The typical testing cycle is burst a node, check it, unburst it, modify the `cloud-init` script, and repeat.

3.6.1.3 Disabling Public IP Address

Once your scenario is working, you can disable its public IP address:

1. Log in to PBS Cloud.
2. Click Cloud.
3. Under Infrastructure, click Bursting.
4. Click the name of the bursting scenario.
5. Disable the public IP address.
6. Click Save.

4 Configuring the Cloud Bursting Hook

4.1 The Cloud Bursting Hooks

PBS Cloud uses two cloud bursting hooks: a main cloud bursting hook and an extension cloud bursting hook. The hook bodies are the same; the difference is in their configuration files.

The main cloud bursting hook is called cloud_hook, and it bursts any non-bare-metal instances. When you install the PBS Cloud module, the installer creates and imports the main cloud bursting hook. This hook comes with a default configuration file, which you then modify, as described in section 4.2, “Configuring the Cloud Bursting Hooks”, on page 55. This configuration file defines all your non-bare-metal scenarios and instances.

The extension cloud bursting hook is called cloud_ext_hook, and it bursts any bare-metal instances. You create this hook if you need it; see section 2.5, “Create Extension Cloud Bursting Hook”, on page 19. The configuration file for cloud_ext_hook is the same as for cloud_hook, except that it defines all your bare-metal scenarios and instances. You create and modify the configuration file for this hook, as described in section 4.2, “Configuring the Cloud Bursting Hooks”, on page 55.

You cannot mix bare-metal and non-bare-metal instances in the same scenario. You cannot mix bare-metal and non-bare-metal scenarios in the same hook configuration file. (No bare-metal in the main hook, and no non-bare-metal in the extension hook.)

Both cloud bursting hooks run at periodic events.

The cloud bursting hooks use PBS Simulate to figure out how many nodes and which jobs to burst.

4.1.1 Default Cloud Bursting Hook Configuration File

```
{
    "pclm_server": "https://<hostname or IP address of PBS Cloud module>:9980/pbspro-cloud/",
    "_comment_pclm_server_example": "e.g. http://control_server.mydomain:9980/pbspro-cloud/",
    "use_node_hour_license": false,
    "_comment_node_hour": "Node Hour License: True for Control, False for PBS Pro",
    "pclm_no_check_ssl_certificate": false,
    "cloud_min_instances": 1,
    "resources":["ncpus", "mem", "ngpus"],
    "cloud_driver": "PclmDriver",
    "plugin": "simulator",
    "plugin_binary_path": "<absolute path to directory containing simsh>",
    "use_custom_snapshot": false,
    "scenario":{
        "<scenario name>":{
            "api_key": "<API key>",
            "cloud_default_image": "<default cloud image for this scenario>",
            "cloud_max_instances": 10,
            "network_max_group_size" : 10,
            "__comment__network_max_group_size "Maximum high speed network size; use for Azure and
    OCI",
            "network_type":"new",
            "__comment__network_type":"available options: [new, auto]",
            "max_nodes_per_burst":50,
            "cloud_node_wait_timeout":180,
            "check_resources":["<resource name>", "<resource name>"],
            "__comment_check_resources":"List of static server-level license tracking resources",
            "preemptable": false,
            "__comment__preemptable": "Scenarios are preemptable or on-demand, not mixed.",
            "__comment__preemptable_example": "Only set to true for supported clouds and scenarios
    with spot/preemptable instances selected."
        },
        "<additional scenario name>":{
            "api_key": "<API key>",
            "cloud_default_image": "<default cloud image for this scenario>",
            "cloud_max_instances": 20,
            "max_nodes_per_burst":50,
            "cloud_node_wait_timeout":180,
            "check_resources":["<resource name>", "<resource name>"],
            "preemptable": false
        }
    }
}
```

4.2 Configuring the Cloud Bursting Hooks

4.2.1 Main Configuration Parameters for Cloud Hooks

The main section of each cloud bursting hook configuration file contains the following parameters:

cloud_driver

Cloud driver used by this cloud bursting hook.

Currently, the only value supported is "PclmDriver". DO NOT change this value.

cloud_min_instances

Required. Minimum number of instances to be present in the cloud at any time, as measured by this cloud bursting hook. Each hook has its own number of instances. Does not apply during startup; cloud nodes are not immediately burst on startup. This is the minimum number that are maintained after they are initially burst on demand.

This value is overridden by the value of the cloud_min_instances resource set at the PBS server.

pclm_no_check_ssl_certificate

Specifies whether or not the cloud bursting hook checks that PBS Cloud has an SSL certificate.

If you set up a self-signed SSL certificate for PBS Cloud, set this to *True* so you can use *https://* for the end-point for PBS Cloud instead of *http://*.

If you have an SSL certificate that is not self-signed, or no certificate, leave this set to *False*.

This should be the same for all scenarios.

Default: *False*; the hook does not check for an SSL certificate

pclm_server

Endpoint for accessing PBS Cloud.

Format: either of these:

http://<PBS Cloud hostname>:<port>/pbspro-cloud/

http://<PBS Cloud IP address>:<port>/pbspro-cloud/

Default port: *9980*

plugin

Name of plugin that figures out which nodes to burst and jobs to run. Currently the only allowed value is "simulator".

Default: "simulator"

plugin_binary_path

Absolute path to directory containing the plugin that figures out which nodes to burst and jobs to run. Currently plugin_binary_path is the absolute path to the directory containing `simsh`.

Default: no default

resources

Resources to be considered for calculating the number of nodes to burst. Resource names must be in quotes.

This does not have to be the same in both hook configuration files.

Use one of the following strings:

- ["ncpus", "mem", "ngpus"]
- ["ncpus", "mem"]

scenario

List of scenarios for this cloud bursting hook. Each scenario has a name and its own configuration parameters, listed below.

You can have one scenario for each cloud provider or multiple scenarios for a cloud provider or both. A scenario can contain either all non-preemptable instances or all preemptable instances. For the main cloud bursting hook, all scenarios must be purely non-bare-metal. For the extension cloud bursting hook, all scenarios must be purely bare-metal.

Each bursting scenario must have its own unique API key. API keys must be unique across all scenarios used by this installation of PBS Cloud; this includes both cloud bursting hooks and all PBS complexes associated with this installation of PBS Cloud.

use_custom_snapshot

Specifies whether to use a custom snapshot or one generated by the hook. See section 4.2.9, "Using Custom Snapshots", on page 62.

Default: *false*

4.2.2 Scenario Configuration Parameters for Cloud Hooks

api_key

API key you generated for a bursting scenario via the PBS Cloud user interface. Each scenario definition in a cloud bursting hook configuration file can have only one API key. Each API key must be unique across all scenarios used by this installation of PBS Cloud; this includes both cloud bursting hooks and all PBS complexes associated with this installation of PBS Cloud.

check_resources

Specifies list of static consumable server-level license-tracking resources to check for license availability.

For creating and updating license tracking resources, see section 3.2.4, "Manage Application Licenses for Cloud Jobs", on page 27.

Format: comma-separated list of quoted resources, enclosed in square brackets

This does not have to be the same in both hook configuration files.

Examples:

```
"check_resources": [],
```

or

```
"check_resources": ["App1", "App2"],
```

Default: no default

cloud_default_image

Default OS image to use when bursting a cloud node. This is the OS image you create via the vendor interface. Overridden when the OS image is provided at job submission via the `qsub` command. Same default OS image as in default_chunk.cloud_node_image for scenario queue.

cloud_max_instances

Maximum number of instances that can be made available in the cloud for this scenario. Required.

Must be greater than 0.

Format: Integer

cloud_node_wait_timeout

Maximum time to wait for freshly burst node to become usable. Minimum value: 180 seconds. You can set this to a higher value, but not lower. Because Oracle cloud nodes can take longer to get to a usable state after being burst, we recommend setting this for Oracle to a value such as *900*. For bare metal this needs to be longer, for example 960. See the cloud provider instructions.

Default: 180 seconds.

max_nodes_per_burst

Maximum number of nodes allowed to burst in a single hook cycle. Maximum number of cloud node licenses to renew per hook cycle. This is not necessarily the same for both cloud bursting hooks.

network_max_group_size

Limit on number of nodes on a single high speed switch. Depends on resources available at the vendor.

Supported on Azure and OCI only. This is not necessarily the same for both cloud bursting hooks.

Default: 10

network_type

Specifies whether hook should always create a new node group, or first try to use an existing node group. When set to *new*, always creates a new node group. When set to *auto*, hook tries to use existing group first.

Default: *new*

preemptable

Specifies whether this scenario supports preemptable or spot instances.

Default: False

use_node_hour_license

This parameter must be set to *false* for PBS Cloud.

Default: False

4.2.3 Steps to Configure Cloud Bursting Hooks

To summarize the process, you create a separate configuration file for each cloud bursting hook; you export the default cloud bursting hook configuration file, edit it for your site and add scenarios, and import it into the appropriate cloud bursting hook. Then you set each hook's frequency and alarm timeout, and enable each hook.

You can create as many scenarios as you need for each hook.

1. Log in to the PBS server host as root
2. Export the default cloud bursting hook configuration to a file:

   For the main cloud bursting hook:

   ```
   qmgr -c "export hook cloud_hook application/x-config default" > cloud_config.json
   ```

   For the extension cloud bursting hook:

   ```
   qmgr -c "export hook cloud_hook application/x-config default" > cloud_ext_config.json
   ```

3. Edit the cloud hook configuration file:

   a. If you are using a self-signed SSL certificate for PBS Cloud, set the pclm_no_check_ssl_certificate parameter to *True*:

   ```
   "pclm_no_check_ssl_certificate": true,
   ```

   b. Set pclm_server to the endpoint for PBS Cloud:

   Format depends on whether you are using `http` or `https`, and can be one of the following:

   <http/https>://<PBS Cloud hostname>:<port>/pbspro-cloud/

<http/https>://<PBS Cloud IP address>:<port>/pbspro-cloud/

Default port: *9980*

c. Set the value of cloud_min_instances to the minimum number of instances to be present in the cloud at any time. Required for bursting. The value you choose for the main cloud bursting hook may be different from the value you choose for the extension cloud bursting hook.

d. Set resources to a comma-separated list of resources that are to be considered for calculating the number of nodes to burst. Resource names must be in quotes. Use one of the following strings:

- ["ncpus", "mem", "ngpus"]
- ["ncpus", "mem"]

e. Set the path for plugin_binary_path to the absolute path to the directory containing `simsh`.

f. If you are using custom snapshots, set use_custom_snapshot to *true*. See section 4.2.9, "Using Custom Snapshots", on page 62.

g. Create each scenario; see section 4.2.4, "Defining a Scenario in a Cloud Bursting Hook Configuration File", on page 59. For the main cloud bursting hook, no instances in any scenario can use bare metal. For the extension cloud bursting hook, all instances in all scenarios must be bare metal.

4. Import the hook configuration file:

For the main cloud bursting hook:

```
qmgr -c "import hook cloud_hook application/x-config default cloud_config.json"
```

For the extension cloud bursting hook:

```
qmgr -c "import hook cloud_ext_hook application/x-config default cloud_ext_config.json"
```

5. The default cloud bursting hook frequency is 2 minutes (120 seconds). Optionally set the frequency; the format is integer seconds:

For the main cloud bursting hook:

```
qmgr -c "set hook cloud_hook freq=<number of seconds>"
```

For the extension cloud bursting hook:

```
qmgr -c "set hook cloud_ext_hook freq=<number of seconds>"
```

6. Set the alarm timeout in integer seconds. The default cloud bursting hook alarm timeout is 10 minutes (600 seconds). For non-bare-metal, we recommend setting this to less than 20 minutes (1200 seconds). For bare metal, we recommend 960 or more; contact us for recommendations. Consider the following factors:

- Time required to burst nodes in the cloud
- Time required to unburst nodes in the cloud
- Number of cloud queues

For the main cloud bursting hook:

```
qmgr -c "set hook cloud_hook alarm=<number of seconds>"
```

For the extension cloud bursting hook:

```
qmgr -c "set hook cloud_ext_hook alarm=<number of seconds>"
```

7. Each cloud bursting hook is disabled by default. Enable this cloud bursting hook:

For the main cloud bursting hook:

```
qmgr -c "set hook cloud_hook enabled=True"
```

For the extension cloud bursting hook:

```
qmgr -c "set hook cloud_ext_hook enabled=True"
```

4.2.4 Defining a Scenario in a Cloud Bursting Hook Configuration File

When you define a scenario in a cloud bursting hook configuration file, you are telling that cloud bursting hook about a scenario that you have already created using the PBS Cloud interface. The cloud bursting hook uses the API key that you generated using the PBS Cloud interface to identify the correct scenario to burst. We show the relationships between a cloud queue, a scenario definition in the PBS Cloud interface, and a hook configuration file in section 3.1.1, "Overview of Creating Bursting Scenarios", on page 22.

4.2.4.1 Put All Bare Metal Scenarios in Extension Cloud Bursting Hook

The main cloud bursting hook is for **all** non-bare-metal instances: all scenarios and all instances must be non-bare-metal (no instances in any scenario can use bare metal). The extension cloud bursting hook is for all bare-metal instances: all scenarios and all instances **must** be bare-metal. You cannot mix bare-metal and non-bare-metal instances in the same scenario. You cannot mix bare-metal and non-bare-metal scenarios in the same hook configuration file. (No bare-metal in the main hook, and no non-bare-metal in the extension hook.)

4.2.4.2 Prerequisites for Defining a Scenario in a Hook Configuration File

- The PBS Cloud scenario must already exist, have a unique API key, and be enabled. See section 3.3.4, "Create a Bursting Scenario", on page 35.
- The cloud queue for this scenario must already exist and be configured for this scenario. See section 3.2.5, "Create and Configure Cloud Queues", on page 29.

4.2.4.3 Steps to Define a Scenario in a Hook Configuration File

Define each scenario in the "scenario" section, under its own name. You can add as many scenarios as you want.

- Set the value of api_key to the API key you generated for this scenario using the PBS Cloud interface. You can use that API key for only one scenario; each API key can appear only once in any cloud hook configuration file, and in only one PBS Cloud scenario.
- Set the value of cloud_default_image to the OS image identifier (name or ID; see vendor instructions) of the default image that should be used for bursting (this is the OS image you created using the vendor interface). This default should be the same default OS image used in default_chunk.cloud_node_image for the scenario queue. If a job submitter specifies an OS image, that overrides the default.
- Set the value of cloud_max_instances to the maximum number of instances that can be made available in the cloud. Required. Must be an integer greater than 0.
- If you are using a high speed network:
  - Make sure that the value of network_max_group_size conforms to what the vendor can provide. For example, this value should match the value of Maximum number of VMs inside a scale set as specified in an Azure bursting scenario. If you are not using a high speed network, this parameter is ignored.
  - Make sure that the network_type parameter is set to *new*
  - If this scenario is for any bare metal instances, all of its instances must be for bare metal.
- Set the value of max_nodes_per_burst to the maximum number of nodes allowed to burst in a single hook cycle.
- Set the value of cloud_node_wait_timeout to the maximum time to wait for a freshly burst node to become usable.

Oracle cloud nodes can take a longer time to get to a usable state. For Oracle we recommend setting cloud_node_wait_timeout to a larger value, for example *900*. For bare metal this may be even longer, for example 960. See the cloud provider instructions.

Minimum value: 180 seconds. You can set this to a higher value, but not lower.

Default: 180 seconds

- If this scenario requires application licenses, set check_resources to the static consumable server-level resources that track those licenses (these are updated via `cron` scripts, and are **not** the same as the dynamic resources updated by server_dyn_res scripts). For example, if this scenario needs two kinds of application license App1 and App2, and you track them with resources app1_static and app2_static, set check_resources like this:

  ```
  "check_resources": ["app1_static","app2_static"],
  ```

  The cloud bursting hook bursts this scenario only when the listed resources indicate that licenses are available.

  For creating and updating license tracking resources, see section 3.2.4, “Manage Application Licenses for Cloud Jobs”, on page 27.

- Set preemptable to:
  - True: the bursting scenario supports preemptable or spot instances and cloud jobs can be preempted.
  - False: jobs that are run in the cloud should not be preempted.

  Default: *False*

4.2.5 Modifying a Cloud Bursting Hook Configuration File

When you modify either cloud bursting hook configuration file, that hook uses the new configuration information the next time it runs.

1. If you are modifying a scenario, disable bursting for the scenario. See section 7.2.5, “Disabling Bursting for a Scenario and Queue”, on page 165.
2. Log in to the PBS server host as root
3. Export the cloud bursting hook configuration to a file:

   For the main cloud bursting hook:

   ```
   qmgr -c "export hook cloud_hook application/x-config default" > cloud_config.json
   ```

   For the extension cloud bursting hook:

   ```
   qmgr -c "export hook cloud_ext_hook application/x-config default" > cloud_ext_config.json
   ```

4. Edit the cloud hook configuration file as needed.
5. To add or modify a scenario, follow the steps in section 4.2.4, “Defining a Scenario in a Cloud Bursting Hook Configuration File”, on page 59.
6. Re-import the hook configuration file:

   For the main cloud bursting hook:

   ```
   qmgr -c "import hook cloud_hook application/x-config default cloud_config.json"
   ```

   For the extension cloud bursting hook:

   ```
   qmgr -c "import hook cloud_ext_hook application/x-config default cloud_ext_config.json"
   ```

7. If you modified a scenario, re-enable bursting for the scenario; see section 7.2.6, “Re-enabling Bursting for a Scenario and Queue”, on page 165.

4.2.6 Creating a Scenario for a Preemptable or Spot Instance

- If you are changing an existing scenario:
  - Disable bursting for the scenario. See section 7.2.5, “Disabling Bursting for a Scenario and Queue”, on page 165.
  - Make sure the PBS Cloud scenario exists and has only preemptable instance types. If the scenario exists but has non-preemptable instance types:
    1. Create a new PBS Cloud scenario for the instance type
    2. Create and configure a cloud queue for the new scenario
- If the PBS Cloud scenario doesn't exist, create it; see section 3.3.4, “Create a Bursting Scenario”, on page 35

1. Log in to the PBS server host as root
2. Export the cloud bursting hook configuration to a file:

   For the main cloud bursting hook:

   ```
   qmgr -c "export hook cloud_hook application/x-config default" > cloud_config.json
   ```

   For the extension cloud bursting hook:

   ```
   qmgr -c "export hook cloud_ext_hook application/x-config default" > cloud_ext_config.json
   ```
3. To add or modify a scenario, follow the steps in section 4.2.4, “Defining a Scenario in a Cloud Bursting Hook Configuration File”, on page 59.
4. Make sure that the preemptable parameter is set to *true* for the scenario:

   ```
   "preemptable": true
   ```
5. Re-import the hook configuration file:

   For the main cloud bursting hook:

   ```
   qmgr -c "import hook cloud_hook application/x-config default cloud_config.json"
   ```

   For the extension cloud bursting hook:

   ```
   qmgr -c "import hook cloud_ext_hook application/x-config default cloud_ext_config.json"
   ```
6. If you disabled bursting for the scenario, re-enable bursting; see section 7.2.6, “Re-enabling Bursting for a Scenario and Queue”, on page 165.

4.2.7 Deleting a Scenario from the Cloud Bursting Hook Configuration File

1. Disable bursting for the scenario. See section 7.2.5, “Disabling Bursting for a Scenario and Queue”, on page 165.
2. Log in to the PBS server host as root
3. Export the cloud bursting hook configuration to a file:

   For the main cloud bursting hook:

   ```
   qmgr -c "export hook cloud_hook application/x-config default" > cloud_config.json
   ```

   For the extension cloud bursting hook:

   ```
   qmgr -c "export hook cloud_ext_hook application/x-config default" > cloud_ext_config.json
   ```
4. Edit the configuration file: delete the scenario from the "scenario" section.
5. Re-import the hook configuration file:

For the main cloud bursting hook:

```
qmgr -c "import hook cloud_hook application/x-config default cloud_config.json"
```

For the extension cloud bursting hook:

```
qmgr -c "import hook cloud_ext_hook application/x-config default cloud_ext_config.json"
```

6. Re-enable bursting for the scenario; see section 7.2.6, “Re-enabling Bursting for a Scenario and Queue”, on page 165.

4.2.8 Changing PBS Cloud Host or Port

If you will move the PBS Cloud module to a different host or port:

1. Disable bursting for each scenario. See section 7.2.5, “Disabling Bursting for a Scenario and Queue”, on page 165.
2. Log in to the PBS server host as root
3. Export the cloud bursting hook configuration to a file:

   For the main cloud bursting hook:

   ```
   qmgr -c "export hook cloud_hook application/x-config default" > cloud_config.json
   ```

   For the extension cloud bursting hook:

   ```
   qmgr -c "export hook cloud_hook application/x-config default" > cloud_ext_config.json
   ```
4. Edit the cloud hook configuration file as needed.
5. Set pclm_server to the new endpoint for PBS Cloud:

   ```
   http://<IP address or hostname of the PBS Cloud host>:<port number>/pbspro-cloud/
   ```
6. Re-import the hook configuration file:

   For the main cloud bursting hook:

   ```
   qmgr -c "import hook cloud_hook application/x-config default cloud_config.json"
   ```

   For the extension cloud bursting hook:

   ```
   qmgr -c "import hook cloud_ext_hook application/x-config default cloud_ext_config.json"
   ```
7. Re-enable bursting for each scenario; see section 7.2.6, “Re-enabling Bursting for a Scenario and Queue”, on page 165.

4.2.9 Using Custom Snapshots

The cloud bursting hook uses PBS Simulate to figure out how many nodes and which jobs to burst. PBS Simulate uses a snapshot of the PBS Professional configuration. By default the cloud bursting hook provides a snapshot each time the hook runs. If the bursting cycle takes a long time due to snapshot creation, you can provide custom snapshots instead. You can create each custom snapshot by hand, or you can use a `cron` job.

4.2.9.1 Creating Custom Snapshots

1. Use the `--config-only` option to the `pbs_snapshot` command to create the custom snapshot:

   ```
   pbs_snapshot --config-only -o <PBS_HOME>/spool/snapshot_simulate
   ```
2. Edit the cloud bursting hook configuration file and set the use_custom_snapshot parameter to *true*:

   ```
   "use_custom_snapshot": true,
   ```

4.2.9.2 Caveats and Restrictions for Using Custom Snapshots

- The custom snapshot must reside in `$PBS_HOME/spool`, and must be named "snapshot_simulate".
- You need a new snapshot every time you change the configuration of PBS Professional, for example if you change scheduling policy, the scheduling formula, or create a queue.

4.3 Testing Automated Cloud Bursting

4.3.1 Prerequisites for Testing Cloud Bursting Hook

- You have installed PBS Professional, PBS Cloud, and PBS Simulate, configured PBS Professional and PBS Simulate, created a cloud administrator account at your cloud provider and added that account to PBS Cloud, created and configured your cloud provider components including an OS image, and configured PBS Cloud. These steps are outlined in section 3.1, “Overview of Configuring PBS Cloud”, on page 21.
- Make sure the cloud bursting hook is enabled.
- You should have at least one PBS Cloud scenario to test.
- This scenario must be enabled in PBS Cloud; see section 7.2.4, “Enabling or Disabling a Bursting Scenario in PBS Cloud”, on page 164
- You have created a cloud queue for this scenario; see section 3.2.5, “Create and Configure Cloud Queues”, on page 29
- Make sure that the scenarios in the hook configuration file match the scenarios in PBS Cloud, especially whether or not a scenario is preemptable, and whether or not the scenario is for bare metal

4.3.2 Steps to Test Automate Cloud Bursting

1. Log into the PBS server host as root
2. Disable the cloud bursting hooks:

   For the main cloud bursting hook:

   ```
   qmgr -c "set hook cloud_hook enabled=False"
   ```

   For the extension cloud bursting hook:

   ```
   qmgr -c "set hook cloud_ext_hook enabled=False"
   ```

3. Add the scenario you are testing to the cloud bursting hook:
   a. Disable bursting for the scenario. See section 7.2.5, “Disabling Bursting for a Scenario and Queue”, on page 165.
   b. Log in to the PBS server host as root
   c. Export the cloud bursting hook configuration to a file:

      For the main cloud bursting hook:

      ```
      qmgr -c "export hook cloud_hook application/x-config default" > cloud_config.json
      ```

      For the extension cloud bursting hook:

      ```
      qmgr -c "export hook cloud_ext_hook application/x-config default" > cloud_ext_config.json
      ```

   d. To add or modify a scenario, follow the steps in section 4.2.4, “Defining a Scenario in a Cloud Bursting Hook Configuration File”, on page 59.
   e. Re-import the hook configuration file:

      For the main cloud bursting hook:

      ```
      qmgr -c "import hook cloud_hook application/x-config default cloud_config.json"
      ```

      For the extension cloud bursting hook:

      ```
      qmgr -c "import hook cloud_ext_hook application/x-config default cloud_ext_config.json"
      ```

   f. Re-enable bursting for the scenario; see section 7.2.6, “Re-enabling Bursting for a Scenario and Queue”, on page 165.
4. Enable the cloud bursting hooks:

   For the main cloud bursting hook:

   ```
   qmgr -c "set hook cloud_hook enabled=True"
   ```

   For the extension cloud bursting hook:

   ```
   qmgr -c "set hook cloud_ext_hook enabled=True"
   ```

5. Specify that all log events should be captured in the PBS server logs:

   ```
   qmgr -c "set server log_events=2047"
   ```

6. Submit jobs to the cloud queue for this scenario:

   ```
   qsub -l select=1:ncpus=4 -q <scenario queue> TestJobScript.sh
   qsub -l select=1:ncpus=4 -q <scenario queue> TestJobScript.sh
   ```

7. Check the status of the jobs:

   ```
   qstat -s
   ```

8. Tail the PBS Professional server logs:

   ```
   tail -f PBS_HOME/server_logs/<current PBS server log file>
   ```

9. Check the current log file to verify that the relevant cloud bursting hook is started. Search for the name of the cloud bursting hook:

   For the main cloud bursting hook:

   ```
   <PBS server>@<PBS server host>;Hook;<cloud_hook>;started
   ```

   For the extension cloud bursting hook:

   ```
   <PBS server>@<PBS server host>;Hook;<cloud_ext_hook>;started
   ```

10. Log into PBS Cloud and go to your burst scenario. You should see the initiation of the workflow that is triggered by the bursting hook. The workflow should automatically start within a couple of minutes.

11. List the nodes known to PBS Professional in order to verify that the relevant cloud bursting hook has burst cloud nodes:

    ```
    pbsnodes -av
    ```

12. Once a node is burst, jobs should start running. Check the status of the jobs:

    ```
    qstat -s
    ```

13. You should see that any nodes that were burst for the test are unburst after the Idle Before Unburst period has elapsed.

14. Go back to your normal server log levels. Reset the server log_events attribute to its previous value:

    ```
    qmgr -c "set server log_events=<previous value>"
    ```

5
Using Cloud Provider Services

Contents

5.1 Configuring Amazon Web Service Cloud Bursting

5.1.1 Types of Amazon Accounts

Amazon has two kinds of accounts: owner (root user), and AWS Identity and Access Management (IAM) users. Here we outline the steps you will follow below:

1. Create and activate an AWS root user account
2. Use the root user account to create an AWS IAM account and give the account administrator permissions.
3. Use the AWS IAM administrator account to do all administrative tasks. This is the account that PBS Cloud will use to manage cloud nodes.
4. Use the AWS IAM administrator account to create the AWS components required for cloud bursting.

5.1.2 Creating and Activating AWS Owner Account

Create and activate your AWS owner account. See How do I create and activate a new Amazon Web Services account?

5.1.3 Creating an AWS IAM User Account

Follow these steps to create an AWS user account and give this account administrative permissions. See Creating an IAM User in Your AWS Account. During this process, make sure you download a CSV file containing the following:

- Access key ID
- Secret access key

We will remind you of this step.

1. Log in to the AWS console.
2. Using the search box located under AWS services, enter IAM.
3. Click the IAM search result to open the Identity and Access Management dashboard.
4. In the navigation pane on the left-hand side of the web page, click Users.
5. Click Add user.
6. Enter the following information for this user:
   a. For User name, enter a name for the user.
      The name can be anything meaningful to your organization, e.g., pc_clouduser.
   b. For Access type, enable Programmatic access.
      The user requires this type of access because PBS Cloud needs to make API calls or use the AWS CLI. The AWS interface generates an access key ID and a secret access key for the user.
7. Click Next:Permissions.
8. Optional: Click Add user to group. This button may already be selected.
9. Click Create group.

10. Enter the following information to create a group, add the user to the group, and choose a permission policy for the group:
    a. For Group name, enter a group name.
       The name can be anything meaningful to your organization, e.g., pc_cloudgroup.
    b. For Policy type, enable Administrator Access.
       This policy provides full access to AWS services and resources.
11. Click Create group.
    This returns you to the Add user page and enables the new group, indicating that the user is added to the new group.
12. Click Next: Tags.
13. Click Next: Review.
14. Click Create user.
15. Click Download.csv.
16. **Download and sav**e this file in a secure location.
    PBS Cloud will use the access key ID and secret access key in this file to manage cloud nodes.
17. Click Close.
    The new user account is displayed.

5.1.4 Multi-Availability Zone Management on AWS

If you are not familiar with AWS regions, Availability Zones, VPCs or subnets, see the following AWS documentation:

- Regions, Availability Zones, and Local Zones
- VPCs and Subnets

Bursting cloud nodes in multiple Availability Zones allows an HPC complex to distribute the load across a region and take advantage of AWS Spot Instances. To use multiple Availability Zones, your virtual private cloud must have a subnet for each Availability Zone; all these subnets must belong to the same VPC.

Once these prerequisites are met, then it is as simple as providing a comma-separated list of subnets when the bursting scenario is created.

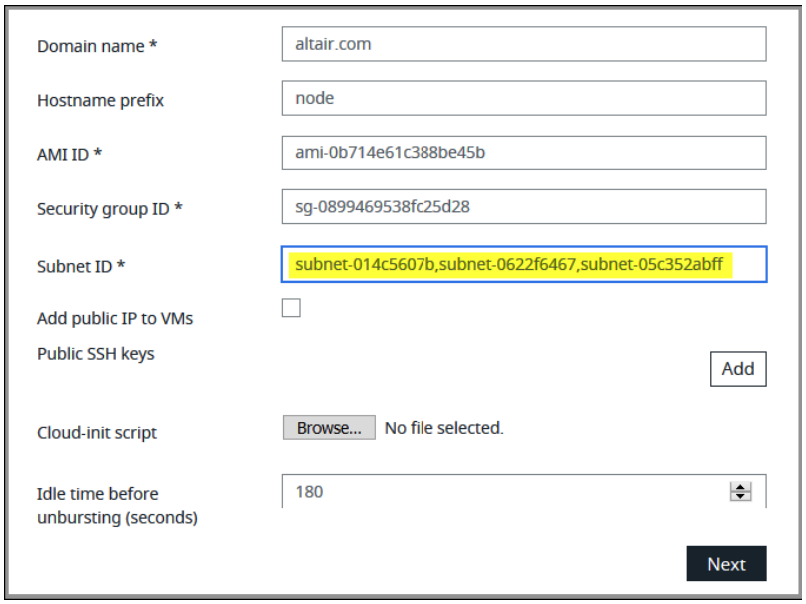

Figure 5-1:List of Subnets

PBS Cloud attempts to burst cloud nodes in the first subnet in the list. If there is no availability in that subnet, then it attempts to burst cloud nodes in the next subnet in the list and will continue until it finds a subnet where it can burst the cloud nodes or until bursting fails because no subnets have availability. The relevant cloud bursting hook attempts to burst all requested cloud nodes in a single subnet. It does not burst cloud nodes across subnets. The cloud bursting hook follows this process each bursting cycle until it finds availability to burst the cloud nodes.

Example 5-1: 10 cloud nodes are requested for bursting.

a. The cloud bursting hook attempts to burst all 10 nodes in subnet-014c5607b.

b. If there is no availability in subnet-014c5607b, the hook attempts to burst all 10 cloud nodes in subnet-0622f6467.

c. If there is no availability in subnet-0622f6467, the hook attempts to burst all 10 cloud nodes in subnet-05c352abff.

d. If there is no availability in subnet-05c352abff, cloud bursting fails for this cycle.

5.1.5 Create a Virtual Private Cloud Network

5.1.5.1 Choose a Region

Log in to your AWS Management Console and choose a region based on the geographical location of your users. All cloud resources that are created are placed in this region.

For more information see Regions and Availability Zones. The menu for selecting a region is located at the upper right-hand corner of the AWS Console menu bar.

Figure 5-2:AWS Region

AWS documentation can be found at Getting Started with IPv4 for Amazon VPC and Working with VPCs and Subnets.

Record the region(s) you selected; you will use this later in the Region parameter in the bursting scenario.

5.1.5.2 Create a VPC

1. Log in to the AWS console.
2. Click aws located in the upper left-hand corner of the web page.
3. Using the search box located under AWS services, enter VPC.
4. Click the VPC search result. The VPC dashboard is opened.
5. In the menu located on the left-hand side of the web page, click Your VPCs.
6. To create a virtual private cloud, click Create VPC.
7. Enter the following to create a VPC:
   a. For Name, enter any name for the VPC.
      The name can be anything meaningful to your organization, e.g., bursting_vpc.
   b. For IPv4 CIDR block, provide an address range in CIDR notation.
   c. For IPv6 CIDR block, enable No IPv6 CIDR Block.
   d. For Tenancy, choose Default.
   e. Click Yes, Create.

5.1.5.3 Create Subnets for the VPC

Create at least one subnet for the VPC. To allow node bursting in several Availability Zones, create a subnet for each Availability Zone that you want to burst in. For more information see Multi-Availability Zone Management on AWS.

1. In the menu located on the left-hand side of the web page, click Subnets.
2. Click Create Subnet.
   a. For Name tag, enter a name for the subnet.
      The name can be anything meaningful to your organization, e.g., bursting_subnet.
   b. For VPC, choose the VPC that was previously created (e.g. bursting_vpc).
   c. For Availability Zone, choose one of the following options:
      - Choose a unique availability zone for each subnet.
      - Choose No Preference to let Amazon choose an Availability Zone for you.
   d. For IPv4 CIDR block, provide an address range in CIDR notation.
   e. Click Create.
3. Click Close.

5.1.6 Create an Internet Gateway

You can SSH into a virtual machine that is used for cloud bursting via an internet gateway. You create an internet gateway and attach it to the bursting VPC. See AWS documentation at Internet Gateways.

1. Log in to the AWS console.
2. Click aws located in the upper left-hand corner of the web page.
3. Using the search box located under AWS services, enter VPC.

4. Click the VPC search result to open the VPC dashboard.
5. In the menu located on the left-hand side of the web page, click Internet Gateways.
6. Click Create internet gateway.
7. Enter a value for Name tag, to be a name for the internet gateway.

   The name can be anything meaningful to your organization, e.g., bursting_gateway
8. Click Create.
9. Click Close.
10. Select the internet gateway that you just created by enabling the check box next to the name of the gateway.
11. You may need to deselect any other internet gateways that are displayed in the list. Amazon creates default resources for your selected region so a default internet gateway may already exist.
12. Click Actions > Attach to VPC.
13. Select the VPC that you created previously (e.g. bursting_vpc).
14. Click Attach.

5.1.7 Update the VPC Route Table

You add a rule to the VPC route table that allows all internet access, and associate the route table with the bursting subnet. You can find AWS documentation at Route Tables.

1. Log in to the AWS console.
2. Click aws located in the upper left-hand corner of the web page.
3. Using the search box located under AWS services, enter VPC.
4. Click the VPC search result to open the VPC dashboard.
5. In the menu located on the left-hand side of the web page, click Route Tables to display a list of route tables.
6. Select the route table attached to your VPC (e.g. bursting_vpc) by enabling the check box next to the name of the route table.

   The VPC column in the route table list specifies the VPC to which the route table is attached.
7. Click the Routes tab at the bottom of the web page.
8. Click Edit routes.

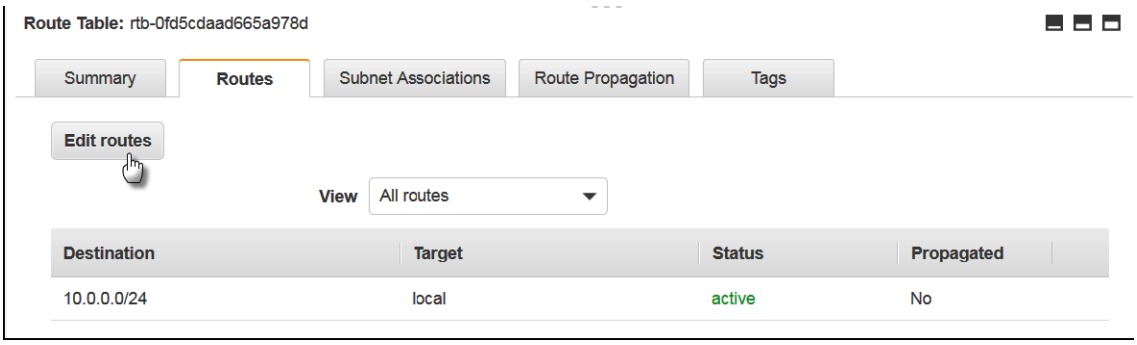

Figure 5-3:Add a Route

9. Click Add route.

10. Enter the following to add a rule that allows all traffic access to the internet gateway:
    - For Destination enter the PBS Cloud firewall IP address.
    - For Target, select Internet Gateway, then the internet gateway that you created previously (e.g. bursting_gateway).
11. Click Save routes.
12. Click Close.
13. Associate the route table to the bursting subnet:
    a. Click the Subnet Associations tab.
    b. Click Edit subnet associations.
    c. Select the subnet you created for cloud bursting from the list.
14. Click Save.

5.1.8 Add Inbound Rules to VPC Security Groups

Add inbound rules to each VPC security group so that a connection can be established with an AWS VM using SSH or RDP.

1. Log in to the AWS console.
2. Click  located in the upper left-hand corner of the web page.
3. Using the search box located under AWS services, enter VPC.
4. Click the VPC search result to open the VPC dashboard.
5. In the menu located on the left-hand side of the web page, under Security, click Security Groups.
6. Select the security groups associated with the VPC you created for cloud bursting by enabling the check box next to their names.

   When you created the VPC, the vendor system created a default VPC security group.
7. Click the Inbound Rules tab at the bottom of the web page.
8. Click Edit rules.
9. Click Add Rule.

10. Add security rules based on your site's requirements. If you enable a public IP address for the associated scenario, there is access to these ports, but the rules here filter who is allowed that access.
    - On Linux platforms, add an inbound rule to allow SSH traffic on port 22.
    - On Windows platforms, add an inbound rule to allow RDP traffic on port 3389.
    - Add the IP address of the PBS Cloud firewall (replace what is here):

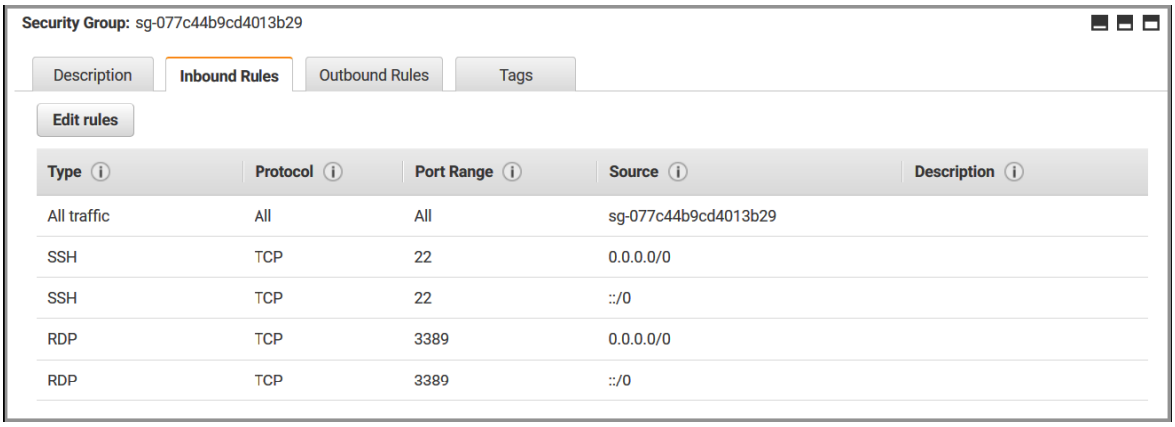

Figure 5-4:Security Rules

Warning: 0.0.0.0/0 enables all IPv4 addresses to access your instance. ::/0 enables all IPv6 address to access your instance. This is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instance.

11. Click Save rules.

5.1.9 Create a Virtual Machine

In this section you create a virtual machine in AWS Elastic Compute Cloud (EC2).

For AWS documentation, see Launch a Linux Virtual Machine and Launching a Virtual Machine with Amazon EC2.

1. Log in to the AWS console.
2. Click aws located in the upper left-hand corner of the web page.
3. Using the search box located under AWS services, enter EC2.
4. Click the EC2 search result to open the EC2 dashboard.
5. In the menu located on the left-hand side of the web page, click Instances.
6. Click Launch Instance.
7. In the menu located on the left-hand side of the web page, click AWS Marketplace.
8. Using the search box:
    - On Linux platforms, choose a Linux platform that is supported for the PBS MoM and press ENTER.
    - On Windows platforms, choose a Windows platform that is supported for the PBS MoM and press ENTER.
9. Locate the appropriate Amazon Machine Image (AMI) and click Select.
10. Click Continue.

11. Select an Instance Type appropriate for your site's workload, based on these criteria:
    - Number of cores
    - Amount of memory
    - Storage
    - Network performance

    Consider the nature of the applications that you plan to deploy on the instance, the number of users that you expect to use the applications, and also how you expect the load to scale in the future. Remember to also factor in the CPU and memory resources that are necessary for the operating system.
12. Click Next: Configure Instance Details.
13. Enter the following to configure instance details:
    a. For Number of instances, specify 1.
    b. For Network, choose the VPC that you previously created (e.g. bursting_vpc). The bursting subnet is populated automatically.
    c. For Auto-assign Public IP, select Enable.
14. Click Next: Add Storage.
15. Specify the storage options your site needs. We recommend enabling Delete on Termination to delete EBS volumes (attached disks) when the virtual machine is terminated.
16. Click Next: Add Tags.
17. Optional: You can add tags for the VM in key-value pairs.
18. Click Next: Configure Security Group.
19. Assign at least one security group to the VM. Enter the following:
    a. For Assign a security group, enable Select an existing security group.
    b. Select the security group that was automatically created for the cloud bursting VPC by enabling the check box next to its name.
20. Click Review and Launch.
21. Review the information about the VM and click Launch.
22. Create a new public/private key pair for the VM. Enter the following:
    a. Select Create a new key pair.
    b. Provide a name for the key pair.
    c. Click Download Key Pair.
    d. Download and save this file in a secure location.

    PBS Cloud will use the information in this .pem file later to SSH into the cloud node.
23. Click Launch Instances.
24. At the bottom of the web page, click View Instances.

    This displays all virtual machines that have been created.

Your virtual machine is ready when the Instance State is "running" and Status Checks are complete. The virtual machine can be accessed via its IPv4 Public IP.

Figure 5-5:Bursting Virtual Machine

5.1.10 Install a PBS MoM on the VM

5.1.10.1 Installing a PBS MoM on a Linux VM

On Linux platforms, the username for logging into the virtual machine is dependent on the Amazon Machine Image (AMI) that you used to create the virtual machine. For example, the username for a CentOS AMI is "centos". Typically you log in as "centos", using your SSH key, then switch to root:

sudo -

For information about usernames and instructions for connecting and copying files to the Linux virtual machine see Connecting to Your Linux Instance Using SSH.

To establish a connection to the VM, you need the .pem file you downloaded while creating the VM.

1. Copy the PBS Professional installer package to the virtual machine. Use scp to copy the tarball file from the PBS server host to the virtual machine. For more information, see Transferring Files to Linux Instances from Linux Using SCP.
2. Log in to your site's PBS Professional server host.
3. SSH into the virtual machine as the user "centos" using the .pem file and the IPv4 Public IP assigned to the VM:

   `ssh -i /<path to .pem file>/<.pem file> centos@<public IP address of virtual machine>`

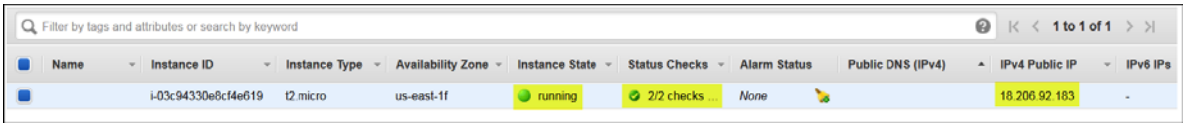

Figure 5-6:Bursting Virtual Machine

4. Switch to root:

   `sudo -i`

5. Copy the PBS Professional installation package to the VM.
6. Using the PBS Professional Installation and Upgrade Guide, install and configure the PBS Professional MoM.
7. Configure the VM to work with your site environment, for example mounting file systems, connecting to the authentication service, installing any applications you need, etc. We recommend that you include the following:
   - Mount `/home` in the VM
   - Either install applications in the VM or cross-mount them from the PBS server host
   - Either add users to the password file or connect the VM to a service such as NIS
8. If `cloud-init` is not installed, install it.

5.1.10.2 Installing the PBS MoM on the Windows VM

Use an RDP client to access the virtual machine. You can establish a connection to the Windows virtual machine through the AWS EC2 console. See Connect to Your Windows Instance for more information.

You will need the .pem file downloaded while creating the VM to establish a connection.

You will copy the PBS Professional installer package to the virtual machine, and use RDP to map a local drive to get access to the installer package. For more information, see Transfer Files to Windows Instances.

1. Log in to the AWS console.
2. Click  located in the upper left-hand corner of the web page.
3. Using the search box located under AWS services, enter EC2.
4. Click the EC2 search result.
5. In the menu located on the left-hand side of the web page, click Instances.
6. Select the Windows virtual machine created for cloud bursting by enabling the check box next to its name.
7. At the top, click Connect.
8. Click Get Password.
9. Browse to the .pem file downloaded while creating the VM.
10. Open the .pem file.
11. Click Decrypt Password.
12. Hover over the decrypted password. You will see a copy to clipboard icon.
13. Click the copy to clipboard icon.
14. Click Download Remote Desktop File.
15. Open the file.
16. Click Connect.
17. For Password, paste the password copied to the clipboard.
18. Click OK.
19. Click Yes to connect, even if there are certificate errors.

    A connection is established with the Windows virtual machine.
20. Copy the PBS Professional installation package to the VM.
21. Using the PBS Professional Installation and Upgrade Guide, install and configure the PBS Professional MoM.
22. Configure the VM for your site's environment, for example mounting file systems, connecting to the authentication service, installing any applications, etc.

5.1.11 Add Authentication and Encryption

5.1.11.1 Add Authentication via MUNGE

Configure your instance to use MUNGE to authenticate users and daemons.

To configure authentication on the instance that you will use as your image source, use MUNGE:

1. Log in as root
2. Download and install a supported version of MUNGE. You can get MUNGE either via your Linux distribution package repositories or from the MUNGE project directly.

   Follow the MUNGE installation instructions at https://github.com/dun/munge/wiki/Installation-Guide.
3. On the PBS server host, generate the munge.key file using the create-munge-key command.
4. On every host, if the library name is not exactly "libmunge.so", for example "libmunge.so.2", add a soft link to it. For example:

   ```
   ln -s /lib64/libmunge.so.2 /lib64/libmunge.so
   ```
5. Copy /etc/munge/munge.key from the PBS server host to the source instance:

   ```
   # scp $PBS_SERVER:/etc/munge/munge.key /etc/munge/munge.key
   ```
6. Start MUNGE:

   ```
   systemctl start munge
   ```
7. Make sure that on the PB server host, the PBS configuration file (/etc/pbs.conf) contains these lines:

   ```
   PBS_AUTH_METHOD=MUNGE
   PBS_SUPPORTED_AUTH_METHODS="pwd,munge"
   ```
8. On your source instance that you will use to burst nodes, edit the PBS configuration file (/etc/pbs.conf) and add this line:

   ```
   PBS_AUTH_METHOD=MUNGE
   ```
9. Restart the PBS MoM:

   ```
   systemctl restart pbs
   ```

For information about configuring encryption for PBS Professional, see "Authentication for Daemons & Users" on page 508 in the PBS Professional Administrator's Guide.

5.1.11.2 Add Encryption via TLS

Configure your instance to use TLS to encrypt communication.

To configure encryption on the instance that you will use as your image source, use TLS:

1. Log in as root
2. Edit PBS configuration file pbs.conf, and set the PBS_ENCRYPT_METHOD parameter:

   ```
   PBS_ENCRYPT_METHOD=tls
   ```
3. Make it so we can use the value of PBS_HOME in pbs.conf:

   ```
   # source /etc/pbs.conf
   ```
4. Create certificate directory PBS_HOME/certs:

   ```
   # mkdir ${PBS_HOME}/certs
   ```

5. Copy files from the PBS server host certificate directory into the VM certificate directory:
   a. Copy your cert.pem file to ${PBS_HOME}/certs/cert.pem:
      # scp $PBS_SERVER:${PBS_HOME}/certs/cert.pem ${PBS_HOME}/certs/cert.pem
   b. Copy your key.pem file to ${PBS_HOME}/certs/key.pem:
      # scp $PBS_SERVER:${PBS_HOME}/certs/key.pem ${PBS_HOME}/certs/key.pem
6. Set permissions and ownership for certificate directory:
   a. Make sure that permissions for the certificate directory and its contents are *0600:*
      # chmod -R 0600 ${PBS_HOME}/certs
   b. Make sure the owner is root on Linux or Administrator on Windows:
      # chown -R root: ${PBS_HOME}/certs
7. Restart PBS MoM:
   - On every Linux host in the complex:
     # <path to start/stop script>/pbs restart
     or
     # systemctl start pbs
   - On every Windows execution host in the complex:
     net stop pbs_mom
     net start pbs_mom

For information about configuring encryption for PBS Professional, see "Encrypting PBS Communication" on page 517 in the PBS Professional Administrator's Guide.

5.1.12 Create an OS Image

In the following steps, you will create an image of the virtual machine you have configured.

You can find AWS documentation at Create an AMI from an Amazon EC2 Instance.

1. Log in to the AWS console.
2. Click  located in the upper left-hand corner of the web page.
3. Using the search box located under AWS services, enter EC2.
4. Click the EC2 search result to open the EC2 dashboard.
5. In the menu located on the left-hand side of the web page, click Instances.
6. Select the virtual machine created for cloud bursting by enabling the check box next to its name.
7. At the top, click Actions > Instance State > Stop.
8. Click Yes, Stop.

   It may take some time for the virtual machine to be stopped.

   Do not proceed until the Instance State is "Stopped".
9. Click Actions > Image > Create Image.
10. For Image name, enter a name for the image.

    The name can be anything meaningful to your organization, e.g., bursting_image.

On Windows platforms, the name of the image must contain the string "windows" (case-insensitive). For example, Windows_Server-2012-R2__RTM-English-64Bit-Base-2019.11.13.

11. Click Create Image.
12. Click the View pending image ami-xxxxxxxxxx link. The image is complete when its Status is "available".
13. You can delete the virtual machine now to avoid storage costs, or keep the virtual machine and update it over time to create updated OS images for bursting. You will incur storage costs, but this is an effective way to keep your OS images up to date when there are changes in packages, patches, or applications.

5.1.13 Collect Information for an AWS Cloud Bursting Scenario

5.1.13.1 Scenario Parameters to Collect at Vendor Interface

Make sure that you capture the following scenario parameters. We will remind you about them:

Table 5-1: Scenario Parameters for Amazon Web Services (AWS)

Scenario Parameter	What to Collect During Configuration at Vendor	Format
Cloud account	Name of your account at cloud vendor	String
Region	Region selected during configuration at cloud vendor	Drop-down list
Domain name	Domain used by cloud nodes	String
Hostname prefix	Optional prefix for burst node names; default is "node"; chosen during configuration at vendor	String
AMI ID	Name of image to be burst; chosen during configuration at vendor	String
Security Group IDs	List of security group IDs associated with VPC and VM created at vendor	Comma separated string
Subnet ID	Name of security group subnet for bursting VPC created at vendor. To burst nodes in multiple Availability Zones, save a comma-separated list of subnet IDs	String

5.1.13.2 Steps to Collect Information

1. Open a browser window and log in to your AWS Management Console.
2. Click aws located in the upper left-hand corner of the web page.
3. Using the search box located under AWS services, enter EC2.
4. Click the EC2 search result to open the EC2 dashboard.
5. In the menu located on the left-hand side of the web page, click AMIs.
6. Select the Amazon Machine Image (AMI) you created for cloud bursting by enabling the check box next to its name.
7. In the Details tab located at the bottom of the web page, hover over the AMI ID so that the interface displays a copy to clipboard icon.
8. Click the copy to clipboard icon.

9. **Save the image name** to use for the AMI ID scenario parameter.
10. In the menu located on the left-hand side of the web page, under NETWORK & SECURITY, click Security Groups.
11. Select the security groups associated with the VPC and the VM by enabling the check box next to each Group ID.
12. In the Description tab located at the bottom of the web page, hover over the Group ID so that the interface displays a copy to clipboard icon.
13. Click on the copy to clipboard icon.
14. **Save the security group IDs** to use for the Security Group IDs scenario parameter.
15. Click  located in the upper left-hand corner of the web page.
16. Using the search box located under AWS services, enter VPC.
17. Click the VPC search result to open the VPC dashboard.
18. In the menu located on the left-hand side of the web page, click Subnets.
19. Select subnets for the bursting VPC by checking the box next to their names. Subnets are required in order to make multiple availability zones work.
20. In the Description tab located at the bottom of the web page, hover over the Subnet ID so that the interface displays a copy to clipboard icon.
21. Click the copy to clipboard icon.
22. **Save the security group subnet name** to use for the Subnet ID scenario parameter. To use cloud nodes in several Availability Zones, save a comma-separated list of subnet IDs.

5.2 Configuring Microsoft Azure Cloud Bursting

5.2.1 Prerequisites

Purchase an Azure subscription, get a tenant ID, and get an Azure user account. For more information about subscriptions see What is an Azure subscription. For more information about tenants see How to get an Azure Active Directory tenant.

5.2.2 Register PBS Cloud with Azure

You can find Azure documentation at Quickstart: Register an application with the Microsoft identity platform.

As you work through this section, save the following information in a file. We will remind you about these:

Table 5-2: Account Parameters for Microsoft Azure

Account Parameter	What to Collect During Configuration at Vendor	Format
Client ID	Application ID generated when registering PBS Cloud with the Azure Active Directory	String
Secret Key	Secret Key generated during account creation at vendor	String
AD Tenant ID	Azure tenant ID generated during account creation at vendor	String
Subscription ID	Subscription ID generated during account creation at vendor	String

1. Register PBS Cloud with the Azure Active Directory and create a client secret key:
   a. Log in to to your Microsoft Azure account.
   b. Using the search box, enter app reg. You will see a list of search results.
   c. Under Services, click App registrations.
   d. Click New registration.
   e. Enter the following to register PBS Cloud with the Azure Active Directory:
      1. For Name, enter the name you will use for PBS Cloud at the vendor.

         The name can be anything meaningful to your organization, e.g., pbs_cloud
      2. For Supported account types, choose the option that best suits your organization. Click the Help me choose link for additional information about the available options.
      3. For Redirect URI, select Web and enter the URL https://<PBS Cloud host name or IP address>:<PBS Cloud port>/pc. The default PBS Cloud port is 9980.

where hostname is the hostname of the machine where the PBS Cloud web interface is installed. This is the URL that is used to log in to PBS Cloud.

f. Register the application: click Register.

Once the application registration is complete, its details are displayed, including an Application ID.

g. To get the application ID for PBS Cloud, hover over the Application (client) ID and click the copy-to-clipboard icon when it appears.

h. **Store the application ID to a file**. You will need this later when you add the vendor cloud account to PBS Cloud.

1. Create a client secret key for PBS Cloud:

a. Under, Manage, click Certificates and secrets.

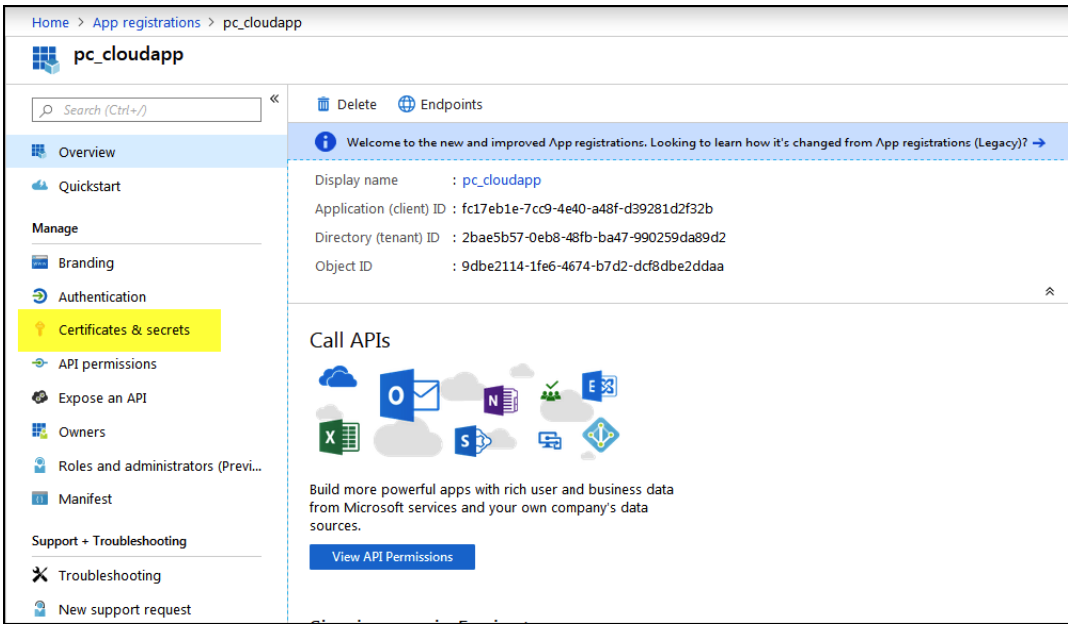

Figure 5-7:Certificates and Secrets

b. Under Client secrets, click New client secret.

c. Enter the following to add a client secret:

1. For DESCRIPTION, enter pc_client_secret.
2. For EXPIRES, select Never.

d. Click Add to generate the client secret key.

You will see the client secret key under the heading VALUE.

e. Click the copy icon next to the client secret key.

f. **Store the client secret key to a file**. The client secret key is used later to create a cloud account in PBS Cloud.

2. Get your Azure subscription ID:
   a. Using the search box, enter subscription. A list of search results is listed.
   b. Under Services, click Subscriptions.
   c. Locate and click your subscription to see details about the subscription, including its Subscription ID.
   d. Hover over the Subscription ID and click on the copy icon when it appears.
   e. **Store the Subscription ID value to a file**. You will use the Subscription ID later when you add the vendor cloud account to PBS Cloud.
3. Assign an access control role to PBS Cloud.
   a. Click Access control (IAM).

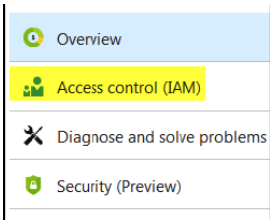

Figure 5-8:Add Access Controls

   b. Click Add.
   c. Click Add role assignment.
   d. In the Add role assignment panel, enter the following to assign a role to PBS Cloud.
      1. For Role, select Contributor.
      2. For Assign access to, select Azure AD user, group, or service principal.
      3. For Select, search for the newly registered application by entering its name, e.g., pbs_cloud.
      4. Select the application by clicking on it.
   e. Click Save.
4. Obtain your Azure tenant ID:
   a. At the top of the web page, click ?.
   b. Click Show diagnostics.

      A dialog box is displayed allowing a file called PortalDiagnostics.json to be saved.
   c. Open the file using any text editor.
   d. Search for tenantId.
   e. **Store the value of tenantId to a file**. You will use the Tenant ID later to add the vendor cloud account to PBS Cloud.

5.2.3 Create a Resource Group

Azure documentation can be found at Manage Azure resources through portal.

A resource group is container that holds related resources for an Azure solution. The resource group can include all the resources for the solution, or only those resources that you want to manage as a group. You decide how you want to allocate resources to resource groups based on what makes the most sense for your organization. Once the resource group is created, resources that are placed into the resource group are a virtual network, a virtual machine, and an image of the virtual machine.

1. Log in to your Microsoft Azure account.
2. Using the search box, enter resource groups. A list of search results is listed.
3. Under Services, click Resource Groups.
4. Click Add.
5. Enter the following to configure the basic settings for the resource group:
   a. For Project Details enter the following:
      - For Subscription, choose the subscription to be billed for the use of the VM.
      - For Resource group, enter a name for the resource group.

        The name can be anything meaningful to your organization, e.g., bursting_resource_group.
   b. For Resource Details enter the following:
      - For Region, select a location based on the geographical location of users.
6. Click Review + create.
7. Click Create.

It may take a moment to create the resource group. All resources (networks, virtual machines, etc.) that are created are placed within this resource group. The name of the resource group is required for creating a bursting scenario in PBS Cloud.

5.2.4 Create a Virtual Network

Azure documentation can be found at Virtual Network Documentation.

1. Log in to your Microsoft Azure account.
2. Using the search box, enter virtual networks. A list of search results is listed.
3. Under Services, click Virtual networks.
4. Click Add.
5. For Name, enter a name for the virtual network.

   The name can be anything meaningful to your organization, e.g., bursting_virtual_network
6. For Address space, enter an address range for the network using CIDR notation.
7. For Subscription, select the same subscription as was selected for the previously created resource group.
8. For Resource group, select the previously created resource group.
9. For Location, select the same geographical location as was selected for the previously created resource group.
10. For Subnet, enter the following:
    a. For Name, enter a name for the virtual machine's subnet.

       The name can be anything meaningful to your organization, e.g., bursting_subnet
    b. For Address range, enter an address range for the subnet in CIDR notation.
11. Click Create.

It may take a moment to create the virtual network. The name of the virtual network is required for creating a bursting scenario in PBS Cloud.

5.2.5 Create a Virtual Machine

You may want to view the following web page to learn about Azure Managed Disks before creating a VM. Additionally, a video is available from Microsoft that shows how to create a virtual machine: Create a Linux Virtual Machine.

1. Log in to your Microsoft Azure account.
2. Using the search box, enter virtual machines. A list of search results is listed.
3. Under Services, click Virtual machines.
4. Click Add.

Enter the following to configure the basic settings for the virtual machine:

5. For Project Details enter the following:
   a. For Subscription, choose the subscription to be billed for the use of the VM.
   b. For Resource group, choose the previously created resource group.
   c. For Virtual machine name, enter a name for the virtual machine.
      The name can be anything meaningful to your organization, e.g., bursting-vm.
   d. For Region, select the same geographical location as was selected for the previously created resource group.
   e. For Availability options, choose No infrastructure redundancy required.
   f. For Image, click the Browse all public and private images link.
   g. Using the search box:
      - On Linux platforms, enter CentOS 7 or RHEL 7 and press ENTER.
      - On Windows platforms, enter Windows and press ENTER.
   h. Locate the appropriate image and select it.
      - On Linux platforms, cloud bursting has been tested on on CentOS 7.2 - 7.6.
      - On Windows platforms, cloud bursting has been tested on Windows 10 and Windows Server 2012.
   i. For Size, click the Change size link and select an instance size appropriate for your site's workload based on:
      - the number of cores
      - the amount of memory
      - storage
      - network performance

      Consider the nature of the applications that you plan to deploy on the instance, the number of users that you expect to use the applications, and also how you expect the load to scale in the future. Remember to also factor in the CPU and memory resources that are necessary for the operating system.
   j. Click Select.
6. For Administrator Account, enter a user account :

This user will have sudo rights and will be able to connect to the VM to install the PBS MoM.

- On Linux platforms:
  - For Authentication type, enable SSH public key.
  - For Username, enter a username of a user account that exists on your site's PBS Server.
  - For SSH public key, copy the SSH public key (i.e., id_rsa.pub) of the user account and paste it.
- On Windows platforms:
  - For Username, enter a username.
  - For Password, enter a password.

7. For Inbound Port Rules, enter the following:
   a. For Public inbound ports, enable Allow selected ports.
   b. For Select inbound ports:
      - For Linux platforms, enable SSH (22).
      - For Windows platforms, enable RDH (3389).
8. Click Next.

Enter the following to configure the storage settings for the virtual machine:

9. For Disk Options, enter the following:
   a. For OS disk size, choose an appropriate disk size based on your site's needs.
   b. For OS disk type, choose one of the following options:
      - Premium SSD
      - Standard SSD
      - Standard HDD

      Choose SSD for I/O-intensive applications, where low latency and high throughput are critical. For testing, consider HDD to keep costs down, as you scale up and down quickly.
1. For Advanced, enter the following:
   a. Click Advanced.
   b. For Use managed disks, choose one of the following options:
      - Yes to use managed disks.
      - No to not use managed disks.

      Enable this feature to have Azure automatically manage the availability of disks to provide data redundancy and fault tolerance, without creating and managing storage accounts on your own. This option is recommended by Azure as it is a lot more scalable.
1. Click Next.

Enter the following to configure the networking settings for the virtual machine:

2. For Network Interface, enter the following:
   - For Virtual network, choose the virtual network previously created.
3. Click Review + create.
4. Click Create.

   It may take a few minutes for the VM to be deployed. You will use this virtual machine to create an OS image.

Once the virtual machine is deployed a message is displayed indicating success, click on Go to resource.

5.2.6 Install a PBS MoM on the VM

5.2.6.1 Install a PBS MoM on a Linux VM

1. Log in to your site's PBS server host as the user account (username and the public SSH key) provided during the creation of the VM.
2. SSH into the virtual machine using the public IP address of the VM:

   ```
   ssh IPV4PublicIP
   ```

   where IPV4PublicIP is the public IP address of the virtual machine.

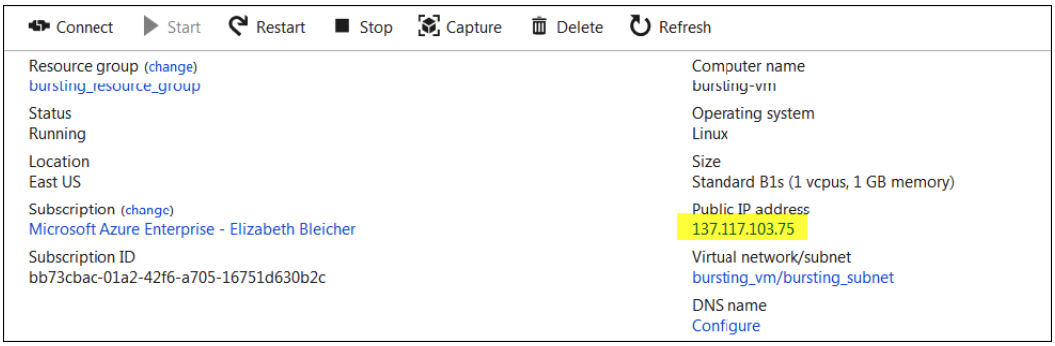

Figure 5-9:Bursting Virtual Machine

3. Enter the command:

   ```
   sudo -i
   ```

4. Copy the PBS Professional installation package to the VM. Use SCP to copy the tarball file from the PBS server host to the virtual machine. For more information, see Move files to and from a Linux VM using SCP.
5. Using the PBS Professional Installation and Upgrade Guide, install and configure the PBS MOM.
6. Configure the VM to work with your site environment, for example mounting file systems, connecting to the authentication service, installing any applications you need, etc. We recommend that you include the following:
   - Mount `/home` in the VM
   - Either install applications in the VM or cross-mount them from the PBS server host
   - Either add users to the password file or connect the VM to a service such as NIS
7. If `cloud-init` is not installed, install it.

5.2.6.2 Install a PBS MoM on a Windows VM

You will use an RDP client to access the virtual machine. A connection can be established to the Windows virtual machine through the Azure portal. For more information see How to connect and sign on to an Azure virtual machine running Windows.

You will copy the PBS Professional installer package to the virtual machine. Use RDP to map a local drive to gain access to the installer package.

1. Log in to the Azure portal.
2. Using the search box, enter virtual machines.
3. Under Services, click Virtual machines.
4. Select the Windows virtual machine created for cloud bursting by clicking its name.

5. Click Connect.
6. Click the RDP tab.
7. Click Download RDP File.
8. Open the file.
9. Click Connect.
10. Enter the password that was established for the Administrator Account when creating the virtual machine.
11. Click OK.
12. Click Yes to connect even if there are certificate errors.

    A connection is established with the Windows virtual machine.
13. Copy the PBS Professional installation package to the VM.
14. Using the PBS Professional Installation and Upgrade Guide, install and configure the PBS MoM.
15. Configure the VM for your site's environment such as mounting file systems, connecting it to the authentication service, installing any applications, etc.

5.2.7 Add Authentication and Encryption

5.2.7.1 Add Authentication via MUNGE

Configure your instance to use MUNGE to authenticate users and daemons.

To configure authentication on the instance that you will use as your image source, use MUNGE:

1. Log in as root
2. Download and install a supported version of MUNGE. You can get MUNGE either via your Linux distribution package repositories or from the MUNGE project directly.

   Follow the MUNGE installation instructions at https://github.com/dun/munge/wiki/Installation-Guide.
3. On the PBS server host, generate the `munge.key` file using the `create-munge-key` command.
4. On every host, if the library name is not exactly "libmunge.so", for example "libmunge.so.2", add a soft link to it. For example:

   ```
   ln -s /lib64/libmunge.so.2 /lib64/libmunge.so
   ```
5. Copy `/etc/munge/munge.key` from the PBS server host to the source instance:

   ```
   # scp $PBS_SERVER:/etc/munge/munge.key /etc/munge/munge.key
   ```
6. Start MUNGE:

   ```
   systemctl start munge
   ```
7. Make sure that on the PB server host, the PBS configuration file (`/etc/pbs.conf`) contains these lines:

   ```
   PBS_AUTH_METHOD=MUNGE
   PBS_SUPPORTED_AUTH_METHODS="pwd,munge"
   ```
8. On your source instance that you will use to burst nodes, edit the PBS configuration file (`/etc/pbs.conf`) and add this line:

   ```
   PBS_AUTH_METHOD=MUNGE
   ```

9. Restart the PBS MoM:

```
systemctl restart pbs
```

For information about configuring encryption for PBS Professional, see "Authentication for Daemons & Users" on page 508 in the PBS Professional Administrator's Guide.

5.2.7.2 Add Encryption via TLS

Configure your instance to use TLS to encrypt communication.

To configure encryption on the instance that you will use as your image source, use TLS:

1. Log in as root
2. Edit PBS configuration file `pbs.conf`, and set the PBS_ENCRYPT_METHOD parameter:

   ```
   PBS_ENCRYPT_METHOD=tls
   ```

3. Make it so we can use the value of PBS_HOME in `pbs.conf`:

   ```
   # source /etc/pbs.conf
   ```

4. Create certificate directory `PBS_HOME/certs`:

   ```
   # mkdir ${PBS_HOME}/certs
   ```

5. Copy files from the PBS server host certificate directory into the VM certificate directory:
   a. Copy your `cert.pem` file to `${PBS_HOME}/certs/cert.pem`:

   ```
   # scp $PBS_SERVER:${PBS_HOME}/certs/cert.pem ${PBS_HOME}/certs/cert.pem
   ```

   b. Copy your `key.pem` file to `${PBS_HOME}/certs/key.pem`:

   ```
   # scp $PBS_SERVER:${PBS_HOME}/certs/key.pem ${PBS_HOME}/certs/key.pem
   ```

6. Set permissions and ownership for certificate directory:
   a. Make sure that permissions for the certificate directory and its contents are *0600:*

   ```
   # chmod -R 0600 ${PBS_HOME}/certs
   ```

   b. Make sure the owner is root on Linux or Administrator on Windows:

   ```
   # chown -R root: ${PBS_HOME}/certs
   ```

7. Restart PBS MoM:
   - On every Linux host in the complex:

     ```
     # <path to start/stop script>/pbs restart
     ```

     or

     ```
     # systemctl start pbs
     ```

   - On every Windows execution host in the complex:

     ```
     net stop pbs_mom
     net start pbs_mom
     ```

For information about configuring encryption for PBS Professional, see "Encrypting PBS Communication" on page 517 in the PBS Professional Administrator's Guide.

5.2.8 Create an OS Image

5.2.8.1 Create a Linux OS Image

Creating an OS image requires the Azure CLI. Refer to these instructions for installing the CLI: How to install the Azure CLI. We recommend installing the CLI on a Windows or Mac machine and then using the command prompt to execute the CLI commands.

Before you can create an OS image of the previously created VM, you must first SSH into the VM and deprovision it. Next you will use the Azure CLI to deallocate and generalize the VM and then create the image. Generalizing the virtual machine removes any SSH keys and DNS settings from the VM.

Follow Step 1 and Step 2 as documented in "How to create an image of a virtual machine or VHD" to create an image of the VM.

Before you can deallocate the virtual machine you may have to execute the following commands to set your subscription to be the active subscription:

```
az account list
az account set --subscription <your subscription ID>
```

You can now delete the virtual machine so that you are no longer charged for it.

5.2.8.2 Create a Windows OS Image

You will generalize the VM using Sysprep. For more information see Create a managed image of a generalized VM in Azure.

1. Log in to the Azure portal.
2. Using the search box, enter virtual machines.
3. Under Services, click Virtual machines.
4. Select the Windows virtual machine created for cloud bursting by clicking its name.
5. Click Connect.
6. Click the RDP tab.
7. Click Download RDP File.
8. Open the file.
9. Click Connect.
10. Enter the password that was established for the Administrator Account when creating the virtual machine.
11. Click OK.
12. Click Yes to connect even if there are certificate errors.
13. Open a Command Prompt window as an administrator.
14. Using Windows Explorer, navigate to the directory C:\Windows\System32\Sysprep.
15. Right-click sysprep.exe and select Run as Administrator.
16. For System Cleanup Action, choose Enter System Out-of-Box Experience (OOBE).
17. Enable the Generalize check box.
18. For Shutdown Options, choose Shutdown.
19. Click OK.

20. Once the VM is shut down, close the RDP session.
21. Navigate to the browser window where the Azure portal is open and the VM details are displayed.
22. Click Capture.
23. For name, enter a name for the image.

    The name of the image should contain the string "windows" (case insensitive). For example, Windows Server 2012 R2 Datacenter.
24. For Resource group, choose the previously created resource group.
25. For Type the virtual machine name, enter the name of the VM.
26. Click Create.
27. You can now delete the virtual machine so that you are no longer charged for it.

5.2.9 Collect Information for an Azure Cloud Bursting Scenario

5.2.9.1 Scenario Parameters to Collect at Vendor Interface

Make sure that you capture the following scenario parameters. We will remind you about each one:

Table 5-3: Scenario Parameters for Microsoft Azure

Scenario Parameter	What to Collect During Configuration at Vendor	Format
Cloud account	Name of your account at cloud vendor	String
Region	Region selected during configuration at cloud vendor	Drop-down list
Domain name	Domain used by cloud nodes	String
Hostname prefix	Optional prefix for burst node names; default is "node"; chosen during configuration at vendor	String
Resource group name	Name of resource group (virtual network, virtual machine, OS image) created at vendor	String
Network name	Name of virtual network created at vendor If the network is in a different resource group from the one specified, enter it as Resource Group Name/Virtual Network Name	String
Subnetwork name	Name of virtual subnet created at vendor	String
Network security group name	Name of network security group for resource group	String

Table 5-3: Scenario Parameters for Microsoft Azure

Scenario Parameter	What to Collect During Configuration at Vendor	Format
Managed Storage	Managed disk feature selected at vendor	Boolean
OS Image	If using managed disks, name of the image. If not using managed disks, Linux Source BLOB URI.	String
Maximum number of VMs inside a scale set with managed storage and a single placement group	Limit selected during configuration at vendor. Default: 100	Integer

5.2.9.2 Steps to Collect Information

Open a browser window and log in to your Microsoft Azure account.

For information on virtual machine scale sets, see the following Azure article about scale sets: What are virtual machine scale sets.

A bursting scenario requires a resource group, but other scenario resources (network, subnet, network security group and the OS image) can all reside in a different resource group. However, the resource groups must be in the same geographic location for this to work.

28. In the menu located on the left-hand side of the web page, click Resource Groups.
29. Copy the name of the resource group created for cloud bursting.
30. **Save the name of the resource group to a file**. You will use this later when you create the bursting scenario.
31. In the menu located on the left-hand side of the web page, click Virtual Networks.
32. Copy the name of the virtual network created for cloud bursting.
33. **Save the name of the network to a file**. You will use this later when you create the bursting scenario.
34. Select the virtual network created for cloud bursting.
35. Click Subnets.

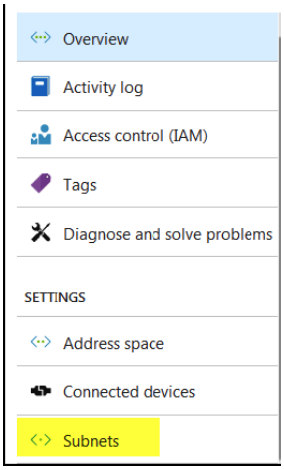

Figure 5-10:Subnet

36. For Subnet name, copy the name of the subnet created for the cloud bursting virtual network.

37. **Save the name of the subnet to a file**. You will use this later when you create the bursting scenario.
38. In the menu located on the left-hand side of the web page, click Resource Groups.
39. Select the Resource Group created for cloud bursting.
40. In the list, locate the Network Security group created for cloud bursting. The Type is Network Security group.
41. Copy the name of the network security group.
42. **Save the name of the network security group to a file**. You will use this later when you create the bursting scenario.
43. In the menu located on the left-hand side of the web page, click Resource Groups.
44. Select the Resource Group created for cloud bursting.
45. In the list, locate the image that was created for cloud bursting. The Type is Image.
46. Select the image.
47. Choose one of the following options:
    - If you chose to use managed disks when you created the VM, copy the name of the image.
    - If you did not choose to use managed disks when you created the VM, copy the Linux Source BLOB URI.
48. **Save the name of the image or the Linux Source BLOB URI to a file**. You will use this later when you create the bursting scenario.

5.3 Configuring Google Cloud Platform Cloud Bursting

5.3.1 Sign Up for a GCP Account

Sign up for a GCP user account. This is different from a GCP service account. Go to the Google Account signup page.

5.3.2 Create a Project

Google Cloud Platform projects form the basis for creating, enabling, and using all Cloud Platform services including managing APIs, enabling billing, adding and removing collaborators, and managing permissions for Cloud Platform resources. GCP documentation can be found at Creating and Managing Projects.

1. Log in to the GCP console.
2. Click  located in the upper left-hand corner of the web page.
3. Click Home.
4. Click Create.
5. For Project Name, enter a name for the project.

   The name can be anything meaningful to your organization, e.g., pc_cloudproject.
6. Click Create.

   It may take a few moments to create the project.
7. Using a browser, navigate to the following URL: https://console.developers.google.com/ apis/library/compute.googleapis.com?project=PROJECTNAME

where PROJECTNAME is the name of the project.

8. Click Enable.

5.3.3 Create a Service Account

GCP documentation can be found at Understanding Service Accounts and Compute Engine IAM Roles .

A service account is a special Google account that is used by applications to use the Google Cloud APIs. PBS Cloud will use a service account to manage cloud nodes.

1. Log in to the GCP console.
2. Click  located in the upper left-hand corner of the web page.
3. Click IAM & admin > Service accounts.
4. Click CREATE SERVICE ACCOUNT.
5. Enter the following to create a service account:
   a. For the Service account name, enter a name for the service account.

      The name can be anything meaningful to your organization, e.g., pc-service-account.
   b. Click CREATE.
   c. For the Project role, click Select a role > Compute Engine > Compute Admin. This role gives full control of all Compute Engine resources.
   d. Click CONTINUE.
   e. Under Create key (optional), click CREATE KEY.
   f. For Key type, enable JSON.
   g. Click CREATE.
   h. **Save the JSON file** in a secure location. Use the dialog box to choose a place to save it. You will need this information later when you add the provider account to PBS Cloud.
6. Make sure you have downloaded a JSON file containing the following:
   - Project ID
   - Client ID
   - Client email
   - Private key ID
   - Private key
7. Click CLOSE.
8. Click DONE.

5.3.4 Create a Virtual Private Cloud Network

GCP documentation can be found at Virtual Private Cloud Documentation and Using VPC Networks .

1. Log in to the GCP console.
2. Click  located in the upper left-hand corner of the web page.
3. Click VPC network > VPC networks.
4. Click CREATE VPC NETWORK.

5. Enter the following to create a VPC:
   a. For the Name, enter a name for the VPC.
      The name can be anything meaningful to your organization, e.g., bursting-vpc.
   b. In the Subnets section, click the Custom tab under Subnet creation mode.
   c. For Name, enter a name for the subnet.
      The name can be anything meaningful to your organization, e.g., bursting-subnet.
   d. For Region, select a Region based on the geographical location of users.
   e. For IP address range, enter an IP address range using CIDR notation
   f. For Private Google access, enable Off.
   g. Click Done.
   h. For Dynamic routing mode, enable Regional.
6. Click Create.
   Creating the VPC network may take some time. Do not proceed until the VPC is created.
7. Select the VPC by clicking on its name.
8. Click the Firewall rules tab.
9. Click CREATE FIREWALL RULE.
10. Enter the following to create a firewall rule:
    a. For Name, enter a name for the firewall rule.
       The name can be anything meaningful to your organization, e.g., ssh-all.
    b. For Direction of Traffic, enable Ingress.
    c. For Action on match, enable Allow.
    d. For Targets, select All instances in the network.
    e. For Source filter, select IP ranges.
    f. For Source IP ranges, enter the IP address of the PBS Cloud firewall
    g. For Protocols and ports, enable Specified protocols and ports.
    h. Enable tcp.
    i. Enter 22.
11. Click Create.

5.3.5 Create a Virtual Machine

GCP documentation can be found at Virtual Machine Instances and Creating and Starting a VM Instance.

1. Log in to the GCP console.
2. Click  located in the upper left-hand corner of the web page.
3. Click Compute Engine > VM instances.
4. Click CREATE INSTANCE.

5. Enter the following to create a virtual machine:

   a. For the Name, enter a name for the virtual machine.

      The name can be anything meaningful to your organization, e.g., bursting-vm.

   b. For Zone, select a zone that is in the same Region as the subnet of the previously created VPC.

   c. In the Machine type, click the Customize link.

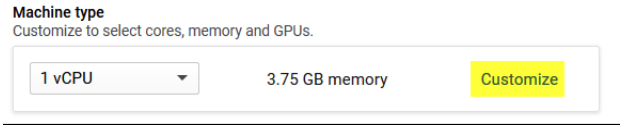

Figure 5-11:Customize the Machine Type

   d. Specify the CPUs, GPUs and RAM.

      Consider the nature of the applications that you plan to deploy on the instance, the number of users that you expect to use the applications, and also how you expect the load to scale in the future. Remember to also factor in the CPU and memory resources that are necessary for the operating system.

   e. For Boot disk, click Change.

   f. Choose CentOS 7.

   g. For Boot disk type, choose one of the following options:

      - Standard persistent disk
      - SSD persistent disk

      Choose SSD for I/O-intensive applications, where low latency and high throughput are critical. For testing, consider Standard persistent disk to keep costs down.

   h. For Size, specify the size of the boot disk.

   i. Click Select.

   j. Under Identity and API access, for Service Account, select No service account.

   k. For Firewall, choose Allow HTTP traffic.

   l. Click Management, disks, networking, SSH Keys.

   m. Click the Networking tab.

   n. Click Add network interface.

   o. For Network, choose the VPC you previously created for bursting.

   p. For Network Service Tier, click Standard.

   q. Click Done.

   r. Delete any default network interfaces that might have been automatically generated.

   s. Click the Security tab.

   t. For SSK Keys, copy the SSH public key (i.e., id_rsa.pub) of the administrator account that exists on your site's PBS server host and paste it.

      This user will have sudo rights and will be able to SSH into the VM to install the PBS MoM.

6. Click Create.

   Creating the virtual machine may take some time.

5.3.6 Install and Configure a PBS MoM on the VM

1. Log in to your site's PBS Server as the user account (public SSH key) provided during the creation of the VM.
2. SSH into the virtual machine using the public IP address of the VM:

   ```
   ssh <public IP address of VM>
   ```

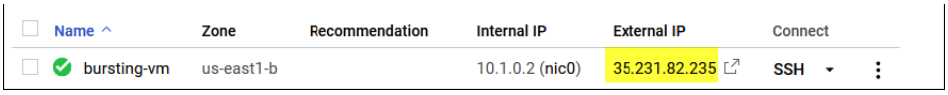

Figure 5-12:Bursting Virtual Machine

3. Switch to root:

   ```
   sudo -i
   ```

4. Using the PBS Professional Installation and Upgrade Guide, install and configure the PBS MOM.
5. Configure the VM to work with your site environment, for example mounting file systems, connecting to the authentication service, installing any applications you need, etc. We recommend that you include the following:
   - Mount /home in the VM
   - Either install applications in the VM or cross-mount them from the PBS server host
   - Either add users to the password file or connect the VM to a service such as NIS
6. If `cloud-init` is not installed, install it.

5.3.7 Add Authentication and Encryption

5.3.7.1 Add Authentication via MUNGE

Configure your instance to use MUNGE to authenticate users and daemons.

To configure authentication on the instance that you will use as your image source, use MUNGE:

1. Log in as root
2. Download and install a supported version of MUNGE. You can get MUNGE either via your Linux distribution package repositories or from the MUNGE project directly.

   Follow the MUNGE installation instructions at https://github.com/dun/munge/wiki/Installation-Guide.
3. On the PBS server host, generate the `munge.key` file using the `create-munge-key` command.
4. On every host, if the library name is not exactly "libmunge.so", for example "libmunge.so.2", add a soft link to it. For example:

   ```
   ln -s /lib64/libmunge.so.2 /lib64/libmunge.so
   ```

5. Copy /etc/munge/munge.key from the PBS server host to the source instance:

   ```
   # scp $PBS_SERVER:/etc/munge/munge.key /etc/munge/munge.key
   ```

6. Start MUNGE:

   ```
   systemctl start munge
   ```

7. Make sure that on the PB server host, the PBS configuration file (`/etc/pbs.conf`) contains these lines:

   ```
   PBS_AUTH_METHOD=MUNGE
   PBS_SUPPORTED_AUTH_METHODS="pwd,munge"
   ```

8. On your source instance that you will use to burst nodes, edit the PBS configuration file (`/etc/pbs.conf`) and add this line:

   ```
   PBS_AUTH_METHOD=MUNGE
   ```

9. Restart the PBS MoM:

   ```
   systemctl restart pbs
   ```

For information about configuring encryption for PBS Professional, see "Authentication for Daemons & Users" on page 508 in the PBS Professional Administrator's Guide.

5.3.7.2 Add Encryption via TLS

Configure your instance to use TLS to encrypt communication.

To configure encryption on the instance that you will use as your image source, use TLS:

1. Log in as root
2. Edit PBS configuration file `pbs.conf`, and set the PBS_ENCRYPT_METHOD parameter:

   ```
   PBS_ENCRYPT_METHOD=tls
   ```

3. Make it so we can use the value of PBS_HOME in `pbs.conf`:

   ```
   # source /etc/pbs.conf
   ```

4. Create certificate directory `PBS_HOME/certs:`

   ```
   # mkdir ${PBS_HOME}/certs
   ```

5. Copy files from the PBS server host certificate directory into the VM certificate directory:
   a. Copy your `cert.pem` file to `${PBS_HOME}/certs/cert.pem`:

      ```
      # scp $PBS_SERVER:${PBS_HOME}/certs/cert.pem ${PBS_HOME}/certs/cert.pem
      ```

   b. Copy your `key.pem` file to `${PBS_HOME}/certs/key.pem`:

      ```
      # scp $PBS_SERVER:${PBS_HOME}/certs/key.pem ${PBS_HOME}/certs/key.pem
      ```

6. Set permissions and ownership for certificate directory:
   a. Make sure that permissions for the certificate directory and its contents are *0600:*

      ```
      # chmod -R 0600 ${PBS_HOME}/certs
      ```

   b. Make sure the owner is root on Linux or Administrator on Windows:

      ```
      # chown -R root: ${PBS_HOME}/certs
      ```

7. Restart PBS MoM:
   - On every Linux host in the complex:

     ```
     # <path to start/stop script>/pbs restart
     ```

     or

     ```
     # systemctl start pbs
     ```

   - On every Windows execution host in the complex:

     ```
     net stop pbs_mom
     net start pbs_mom
     ```

For information about configuring encryption for PBS Professional, see "Encrypting PBS Communication" on page 517 in the PBS Professional Administrator's Guide.

5.3.8 Create an OS Image

GCP documentation can be found at Creating, Deleting, and Deprecating Custom Images.

1. Log in to the GCP console.
2. Click located in the upper left-hand corner of the web page.
3. Click Compute Engine > VM instances. A list of virtual machines is displayed.
4. Click the three vertical dots next to the virtual machine that was created for cloud bursting.

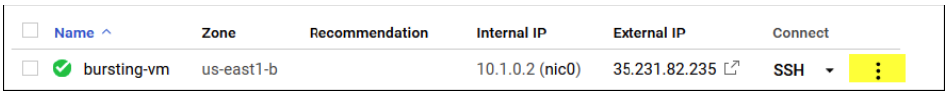

Figure 5-13:Bursting Virtual Machine

5. Click Stop.

   It may take some time for the VM to be stopped. Do not proceed until the VM is stopped.
6. In the menu located on the left-hand side of the web page, click Images .
7. Click CREATE IMAGE.
8. Enter the following to create an image:

   a. For Name, enter a name for the image.

   The name can be anything meaningful to your organization, e.g., bursting-image.

   b. For Source select Disk.

   c. For Source disk, select the previously created virtual machine.
9. Click Create.

   It may take some time to create the image. Do not proceed until the image is created.
10. You can delete the virtual machine now to avoid storage costs, or keep the virtual machine and update it over time to create updated OS images for bursting. You will incur storage costs, but this is an effective way to keep your OS images up to date when there are changes in packages, patches, or applications.

5.3.9 Collect Information for GCP Cloud Bursting Scenario

5.3.9.1 Scenario Parameters to Collect at Vendor Interface

Make sure that you capture the following scenario parameters. We will remind you about each one:

Table 5-4: Scenario Parameters for Google Cloud Platform (GCP)

Scenario Parameter	What to Collect During Configuration at Vendor	Format
Cloud account	Name of your account at cloud vendor	String
Region	Region selected during configuration at cloud vendor	Drop-down list
Domain name	Domain used by cloud nodes	String
Hostname prefix	Optional prefix for burst node names; default is "node"; chosen during configuration at vendor	String

Table 5-4: Scenario Parameters for Google Cloud Platform (GCP)

Scenario Parameter	What to Collect During Configuration at Vendor	Format
Network name	Name of VPC network for cloud bursting created at vendor	String
Subnetwork name	Name of VPC network subnet created at vendor	String
OS Image URI	Choose image, click "REST Equivalent", collect value of "selfLink" name-value pair (This gives path to the OS image)	String

5.3.9.2 Steps to Collect Information

1. Open a browser window and log in to your GCP console.
2. Click  located in the upper left-hand corner of the web page.
3. Click VPC network > VPC networks.
4. Click on the name of the VPC that was created for cloud bursting. VPC network details are displayed.
5. Copy the name of the VPC network.
6. **Save the name of the VPC network**. You will use this later when you create a bursting scenario.
7. Copy the name of the VPC network subnet.
8. **Save the name of the VPC subnet**. You will use this later when you create a bursting scenario.
9. Click  located in the upper left-hand corner of the web page.
10. Click Compute Engine > Images.
11. Select the image created for cloud bursting.
12. Click Equivalent REST
13. Copy the value for the entry called selfLink.
14. **Save this value**. You will use this later when you create a bursting scenario.
15. Click Next.

5.4 Configuring Oracle Cloud Platform Cloud Bursting

While you are working your way through the following sections, make sure you save the items in the following table for later when you add the vendor account to PBS Cloud. We will remind you about them:

Table 5-5: Account Parameters for Oracle

Account Parameter	What to Collect During Configuration at Vendor	Format
User OCID	User OCID generated when creating Oracle cloud user account at vendor	String
Tenant OCID	Tenancy OCID generated at vendor	String
Compartment OCID	Root compartment OCID generated at vendor	String
Fingerprint OCID	Fingerprint generated when adding the public SSH key for Oracle user at vendor	String
Private Key	RSA private key generated at vendor	String

5.4.1 Sign Up for an Oracle Cloud Account

Sign up for an Oracle Cloud account and get an associated tenancy. Oracle documentation can be found at Adding Users and Resource Identifiers.

5.4.2 Create Oracle Cloud User Account

Click ☰ located in the upper left-hand corner of the web page.

1. Log in to the Oracle Cloud Infrastructure console.
2. Click Identity > Users.
3. Click Create User.
4. Enter the following to create the user:
   a. For NAME, enter a name for the user.
      The name can be anything meaningful to your organization, e.g., pc_clouduser.
   b. For DESCRIPTION, enter a description of the user.
5. Click Create.
   The user account is created and displayed in the users list.
6. Click Show located under the name of the user. The user account's OCID is displayed.
7. Click Copy to copy the OCID.
8. **Store the user OCID to a file**. You will need this later when you add the account to PBS Cloud.
9. Click Group from the menu located on the left-hand side of the web page.
10. Click Create Group.

11. Enter the following:
    a. For Name, enter Administrators.
    b. For Description, enter a description for the group.
    c. Click Submit.

    The group is created and is displayed in the Groups list.
12. Click on the name of the group.
13. Click Add User to Group.
    a. For User, select the user that was previously created (e.g., pc_clouduser).
    b. Click Add.
14. Click ☰ located in the upper left-hand corner of the web page.
15. Click Identity > Policies.
16. Click Create Policy.
    a. For Name, enter a name for the policy.
    b. For Policy Versioning, enable Keep Policy Current.
    c. For Policy Statements, enter: ALLOW GROUP Administrators to manage all-resources IN TENANCY
    d. Click Create.

5.4.3 Generating an SSH Public Key for the Oracle Cloud User

You will use OpenSSL to create a private and public key in a PEM format for the previously created Oracle Cloud user. If you're using Windows, you'll need to install Git Bash for Windows and run the commands with that tool.

1. Generate a private key by executing the following command:
   ```
   openssl genrsa -out oracle_private_key.pem 2048
   ```
   We recommend changing the permissions on this file so that only you have read/write access.
2. **Save the private key file**. You will need this later when you add the vendor to PBS Cloud.
3. Generate the public key by executing the following command:
   ```
   openssl rsa -pubout -in oracle_private_key.pem -out oracle_public_key.pem
   ```
4. Log in to the Oracle Cloud Infrastructure console.
5. Click ☰ located in the upper left-hand corner of the web page.
6. Click Identity > Users.
7. Click the name of the previously created user (e.g., pc_clouduser).
8. Click Add Public Key.
9. Copy and paste the contents of the public RSA key file.

10. Click Add to generate a fingerprint:

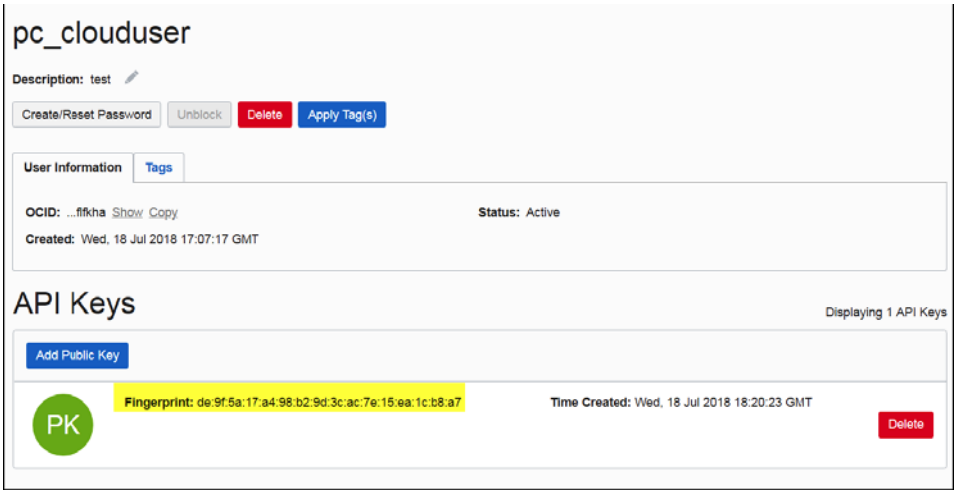

Figure 5-14:Public Key Fingerprint

11. Copy the fingerprint.
12. **Store the fingerprint to a file**. You will need the fingerprint later to add the vendor account to PBS Cloud.

5.4.4 Obtain the Root Compartment Identifier

Oracle documentation can be found at Understand Compartments.

When your tenancy is provisioned, a root compartment is created for you. Compartments can be used to organize and isolate your resources to make it easier to manage and secure access to them. Your root compartment holds all of your cloud resources. You can think of the root compartment like a root folder in a file system. The first time you sign in to the Oracle Cloud Console and select a service, you will see your root compartment. All the resources required for cloud bursting will be contained in this root compartment. You will need the root compartment's resource identifier to add an Oracle cloud account to PBS Cloud.

1. Log in to the Oracle Cloud Infrastructure console.
2. Click ☰ located in the upper left-hand corner of the web page.
3. Click Identity > Compartments.
4. Click Show located under the name of the root compartment. The compartment's OCID is displayed.
5. Click Copy to copy the OCID.
6. **Store the root compartment OCID to a file**. You will need this later when you add the vendor to PBS Cloud.

5.4.5 Obtain the Tenancy Identifier

1. Log in to the Oracle Cloud Infrastructure console.
2. Click ☰ located in the upper left-hand corner of the web page.
3. Click Administration > Tenancy Details.
4. Under Tenancy Information, click Show located to the right of OCID:

The tenancy's OCID is displayed.

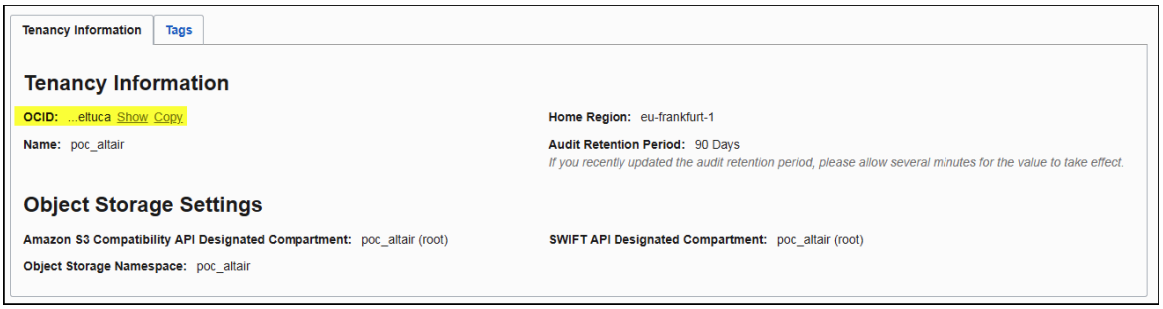

Figure 5-15:Tenancy OCID

5. Click Copy to copy the OCID.
6. **Store the tenancy OCID to a file**. You will need this later when you add the vendor cloud account to PBS Cloud

5.4.6 Create a Virtual Cloud Network

Oracle documentation can be found at Overview of Networking and Creating a Virtual Cloud Network.

Make sure that the VCN has a subnet associated with each of the region's availability domains.

1. Log in to the Oracle Cloud Infrastructure console.
2. Click ☰ located in the upper left-hand corner of the web page.
3. Click Networking > Virtual Cloud Networks.
4. Choose a region based on the geographical location of your users. Use the REGION pull-down menu.
5. Click Create Virtual Cloud Network.
6. Enter the following to create a VCN:
   a. For CREATE IN COMPARTMENT, select the root compartment.
   b. For NAME, enter a name for the VCN.

      The name can be anything meaningful to your organization, e.g., bursting_vcn.
   c. Enable CREATE VIRTUAL CLOUD NETWORK PLUS RELATED RESOURCES.

      Choosing this option automatically creates a VCN with a CIDR block 10.0.0.0/16, an internet gateway, a route rule to enable traffic to and from the internet gateway, the default security list, the default set of DHCP options, and one public subnet per availability domain.
7. Click Create Virtual Cloud Network.

   A summary of the VCN, internet gateway, default route table, and subnets is displayed.
8. Click Close.

A list of VCNs is displayed.

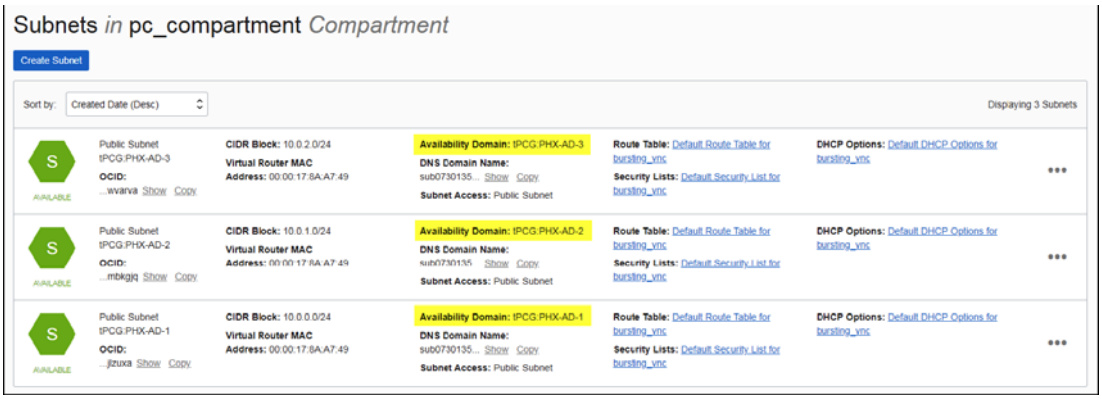

Figure 5-16:Virtual Machine Subnets and Associated Availability Domains

9. Click the name of the VCN.

   The subnets are displayed. A subnet is created for each availability domain (data center) located in the previously selected region.

5.4.7 Check Tenancy Service Limits

When you sign up for Oracle Cloud Infrastructure, a set of service limits are configured for your tenancy. The service limit is the quota or allowance set on a resource. For example, your tenancy is allowed a maximum number of compute instances (virtual machines) per availability domain. These limits are generally established with your Oracle sales representative when you purchase Oracle Cloud Infrastructure. Oracle documentation can be found at Service Limits and Regions and Availability Domains.

When you reach the service limit for a resource, you receive an error when you try to create a new resource of that type. You cannot create a new resource until you are granted an increase to your service limit or you terminate an existing resource.

View your tenancy's limits to ensure that there are sufficient resources available in a region's availability domains.

1. Log in to the Oracle Cloud Infrastructure console.
2. Choose the region where the previously created VCN is hosted. Use the REGION pull-down menu.
3. Click ☰ located in the upper left-hand corner of the web page.
4. Click Governance > Service Limits.
5. Scroll down to the Service Limits section.
6. Click Compute.

Availability domains (data centers) for the region are displayed. For each resource (VM shape) the number of nodes that can be burst in the corresponding availability domains are displayed. In the below example, three nodes can be burst in each data center in the us-phoenix-1 region for the VM Standard1.1 shape.

Resource	Region (us-phoenix-1)		tPCG:PHX-AD-1		tPCG:PHX-AD-2		tPCG:PHX-AD-3	
	Limit	Usage	Limit	Usage	Limit	Usage	Limit	Usage
Custom Images	25	0	*n/a*	*n/a*	*n/a*	*n/a*	*n/a*	*n/a*
VM.DenseIO1.16	*n/a*	*n/a*	0	0	0	0	0	0
VM.DenseIO1.4	*n/a*	*n/a*	1	0	1	0	1	0
VM.DenseIO1.8	*n/a*	*n/a*	0	0	0	0	0	0
VM.DenseIO2.16	*n/a*	*n/a*	0	0	0	0	0	0
VM.DenseIO2.24	*n/a*	*n/a*	0	0	0	0	0	0
VM.DenseIO2.8	*n/a*	*n/a*	0	0	0	0	0	0
VM.Standard1.1	*n/a*	*n/a*	3	0	3	0	3	0
VM.Standard1.16	*n/a*	*n/a*	0	0	0	0	0	0
VM.Standard1.2	*n/a*	*n/a*	3	0	3	0	3	0

Figure 5-17:Virtual Machine Type Limits

7. Verify that the appropriate service limits are set for your tenancy based on the VM shape chosen for the virtual machine and the region's availability domains.

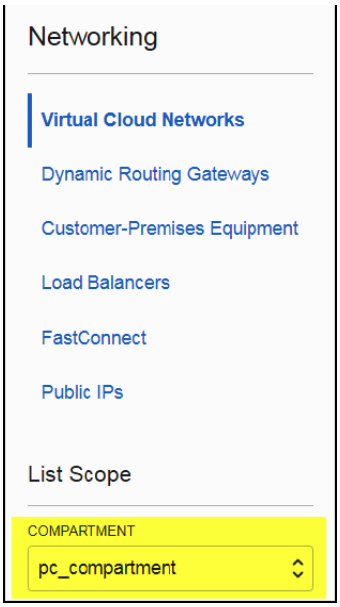
To request an increase a service limits for your tenancy see Requesting a Service Limit Increase.

5.4.8 Creating a Virtual Machine

Virtual machines are hosted in availability domains (data centers) located in a region and are based on predefined VM shapes. Before proceeding, determine the VM shape that your site requires for cloud bursting based on the number of CPUs, memory, disk space, network bandwidth, and virtual network interface cards. While selecting the shape for a VM, consider the nature of the applications that you plan to deploy on the instance, the number of users that you expect to use the applications, and also how you expect the load to scale in the future. Remember to also factor in the CPU and memory resources that are necessary for the operating system.

1. Log in to the Oracle Cloud Infrastructure console.
2. Click ☰ located in the upper left-hand corner of the web page.
3. Click Compute > Instances.
4. Choose the region where the previously created VCN is hosted. Use the REGION pull-down menu.

5. For COMPARTMENT, select the root compartment.



6. Click Create Instance.
7. Enter the following to create a virtual machine:
   a. For NAME, enter a name for the VM.

      The name can be anything meaningful to your organization, e.g., bursting_vm.

   b. For AVAILABILITY DOMAIN, choose one of the region's availability domains.

      The virtual machine is hosted in the chosen availability domain (data center). Choose the availability domain that best suits your site's cloud bursting requirements based on the machine type of the virtual machine (VM shape) and service limits.

   c. For BOOT VOLUME, enable ORACLE-PROVIDED OS IMAGE.
   d. For IMAGE OPERATING SYSTEM, choose CentOS 7.
   e. For SHAPE TYPE, enable VIRTUAL MACHINE.
   f. For SHAPE, select a VM shape.

      Choose the VM shape that best suits your site's cloud bursting requirements based on number of CPUs, memory, disk space, and network bandwidth.

   g. For IMAGE VERSION, select the latest available one.
   h. For BOOT VOLUME CONFIGURATION, enable CUSTOM BOOT VOLUME SIZE and enter a boot volume size in GBs.
   i. Enable PASTE SSH KEYS and copy the SSH public key (i.e., id_rsa.pub) of a user account that exists on your site's PBS Server and paste it.

      This user will have sudo rights and will be able to SSH into the VM to install the PBS MoM.

   j. For VIRTUAL CLOUD NETWORK, choose the VCN that was created for cloud bursting.
   k. For SUBNET, choose the subnet associated with the previously chosen availability domain.
8. Click Create Instance.

Creating the virtual machine may take some time. It is done when the state is "Running".

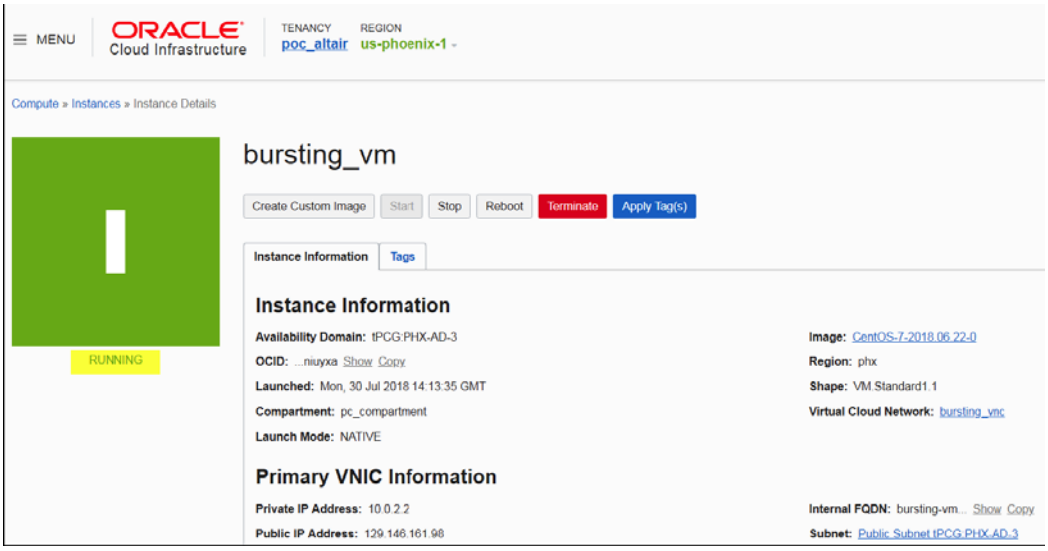


Figure 5-18:Running Virtual Machine

5.4.9 Installing and Configuring a PBS MoM on the VM

1. Log in to your site's PBS Server as the user account provided during the creation of the VM.
2. SSH into the virtual machine using the default user "opc", the private SSH key of the user account provided during the creation of the VM and the External IP assigned to the VM.

   ```
   ssh -i PRIVATE_KEY_PATH opc@PUBLIC_IP_ADDR
   ```

   Where PRIVATE_KEY_PATH is the path to the file that contains the private SSH key of the user account provided during the creation of the VM and PUBLIC_IP_ADDR is the public IP address of the VM.

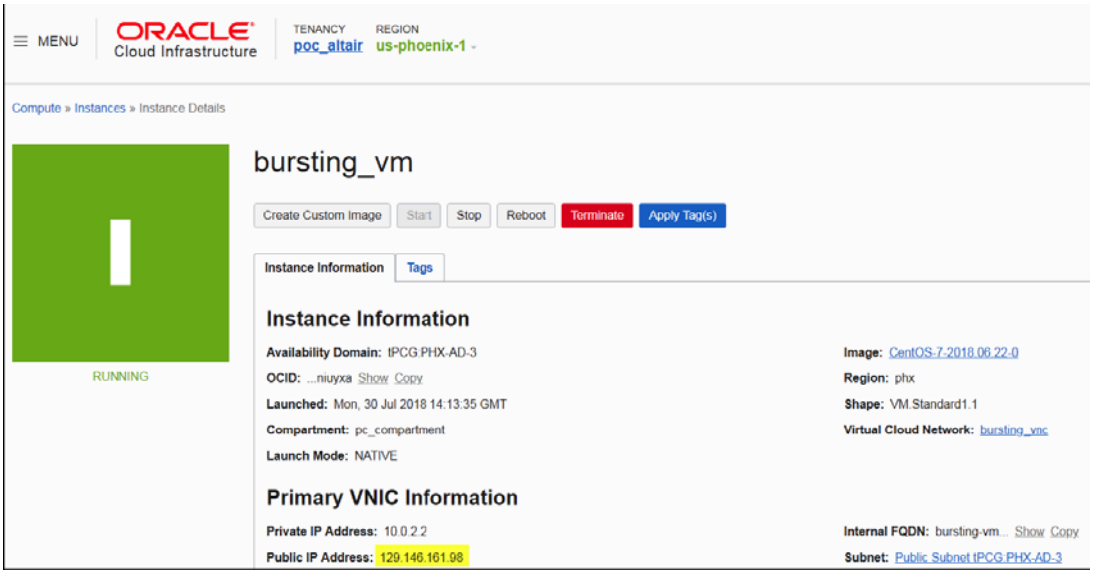

Figure 5-19:Bursting Virtual Machine

3. Switch to root:

   ```
   sudo -i
   ```

4. Using the PBS Professional Installation and Upgrade Guide, install and configure the PBS MOM.
5. Configure the VM to work with your site environment, for example mounting file systems, connecting to the authentication service, installing any applications you need, etc. We recommend that you include the following:
   - Mount /home in the VM
   - Either install applications in the VM or cross-mount them from the PBS server host
   - Either add users to the password file or connect the VM to a service such as NIS
6. If `cloud-init` is not installed, install it.

5.4.10 Add Authentication and Encryption

5.4.10.1 Add Authentication via MUNGE

Configure your instance to use MUNGE to authenticate users and daemons.

To configure authentication on the instance that you will use as your image source, use MUNGE:

1. Log in as root
2. Download and install a supported version of MUNGE. You can get MUNGE either via your Linux distribution package repositories or from the MUNGE project directly.

   Follow the MUNGE installation instructions at https://github.com/dun/munge/wiki/Installation-Guide.
3. On the PBS server host, generate the munge.key file using the `create-munge-key` command.
4. On every host, if the library name is not exactly "libmunge.so", for example "libmunge.so.2", add a soft link to it. For example:

   ```
   ln -s /lib64/libmunge.so.2 /lib64/libmunge.so
   ```
5. Copy /etc/munge/munge.key from the PBS server host to the source instance:

   ```
   # scp $PBS_SERVER:/etc/munge/munge.key /etc/munge/munge.key
   ```
6. Start MUNGE:

   ```
   systemctl start munge
   ```
7. Make sure that on the PB server host, the PBS configuration file (`/etc/pbs.conf`) contains these lines:

   ```
   PBS_AUTH_METHOD=MUNGE
   PBS_SUPPORTED_AUTH_METHODS="pwd,munge"
   ```
8. On your source instance that you will use to burst nodes, edit the PBS configuration file (`/etc/pbs.conf`) and add this line:

   ```
   PBS_AUTH_METHOD=MUNGE
   ```
9. Restart the PBS MoM:

   ```
   systemctl restart pbs
   ```

For information about configuring encryption for PBS Professional, see "Authentication for Daemons & Users" on page 508 in the PBS Professional Administrator's Guide.

5.4.10.2 Add Encryption via TLS

Configure your instance to use TLS to encrypt communication.

To configure encryption on the instance that you will use as your image source, use TLS:

1. Log in as root
2. Edit PBS configuration file pbs.conf, and set the PBS_ENCRYPT_METHOD parameter:

   PBS_ENCRYPT_METHOD=tls
3. Make it so we can use the value of PBS_HOME in pbs.conf:

   # source /etc/pbs.conf
4. Create certificate directory PBS_HOME/certs:

   # mkdir ${PBS_HOME}/certs
5. Copy files from the PBS server host certificate directory into the VM certificate directory:
   a. Copy your cert.pem file to ${PBS_HOME}/certs/cert.pem:

      # scp $PBS_SERVER:${PBS_HOME}/certs/cert.pem ${PBS_HOME}/certs/cert.pem

   b. Copy your key.pem file to ${PBS_HOME}/certs/key.pem:

      # scp $PBS_SERVER:${PBS_HOME}/certs/key.pem ${PBS_HOME}/certs/key.pem
6. Set permissions and ownership for certificate directory:
   a. Make sure that permissions for the certificate directory and its contents are *0600:*

      # chmod -R 0600 ${PBS_HOME}/certs

   b. Make sure the owner is root on Linux or Administrator on Windows:

      # chown -R root: ${PBS_HOME}/certs
7. Restart PBS MoM:
   - On every Linux host in the complex:

     # <path to start/stop script>/pbs restart

     or

     # systemctl start pbs
   - On every Windows execution host in the complex:

     net stop pbs_mom

     net start pbs_mom

For information about configuring encryption for PBS Professional, see "Encrypting PBS Communication" on page 517 in the PBS Professional Administrator's Guide.

5.4.11 Create an OS Image

Oracle documentation can be found at Managing Custom Images.

1. Log in to the Oracle Cloud Infrastructure console.
2. Click ☰ located in the upper left-hand corner of the web page.
3. Click Compute > Instances.

   A list of virtual machines is displayed.
4. Click the name of the virtual machine created for cloud bursting.
5. Click Create Custom Image.

6. Enter the following to create a custom image:
   a. For CREATE IN COMPARTMENT, select the root compartment.
   b. For NAME, enter a name for the image.
      The name can be anything meaningful to your organization, e.g., bursting_image.
7. Click Create Custom Image.
   It may take some time to create the image. Do not proceed until the image is created.
8. You can delete the virtual machine now to avoid storage costs, or keep the virtual machine and update it over time to create updated OS images for bursting. You will incur storage costs, but this is an effective way to keep your OS images up to date when there are changes in packages, patches, or applications.

5.4.12 Collect Information for Oracle Cloud Bursting Scenario

5.4.12.1 Scenario Parameters to Collect at Vendor Interface

Make sure that you capture the following scenario parameters. We will remind you about them:

Table 5-6: Scenario Parameters for Oracle

Scenario Parameter	What to Collect During Configuration at Vendor	Format
Cloud account	Name of your account at cloud vendor	String
Region	Region selected during configuration at cloud vendor	Drop-down list
Domain name	Domain used by cloud nodes	String
Hostname prefix	Optional prefix for burst node names; default is "node"; chosen during configuration at vendor	String
Subnet ID	OCID of subnet associated with data center where cloud bursting virtual machine is hosted,	String
OS Image URI	Vendor link to bursting image OCID	String

5.4.12.2 Steps to Collect Information

Open a browser window and log in to the Oracle Cloud Infrastructure console.

9. Click ☰ located in the upper left-hand corner of the web page.
10. Click Networking > Virtual Cloud Networks.
11. Click the name of the VCN created for cloud bursting.

12. Locate the subnet associated with the availability domain where the cloud bursting virtual machine is hosted.

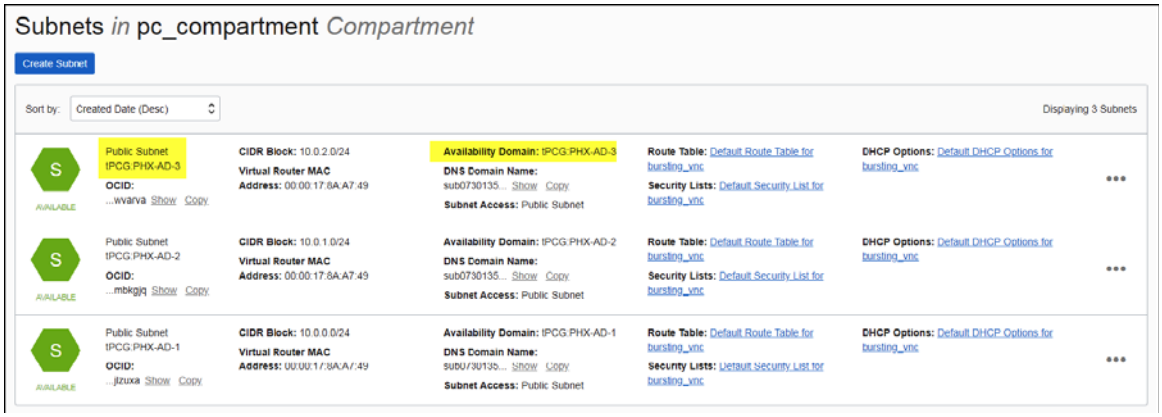

Figure 5-20:Subnet and Associated Availability Domain

13. Click Show located under the name of the subnet.

    The subnet's OCID is displayed.

14. Click Copy to copy the OCID.
15. **Save the subnet OCID to a file**. You will need this later when you create the bursting scenario.
16. Navigate to the Oracle Cloud Infrastructure browser window.
17. Click ☰ located in the upper left-hand corner of the web page.
18. Click Compute > Custom Images. A list of custom images is displayed.
19. Locate the custom image created from the cloud bursting virtual machine.
20. Click the Show link below the name of the image to view the OCID.
21. Click Copy to copy the OCID of the image.
22. **Save the the image OCID to a file**. You will need this later when you create the bursting scenario.

5.5 Configuring Orange Cloud Flexible Engine for Cloud Bursting

5.5.1 Purchase an Orange Business Services Account

Purchase an Orange Business Services account. You will use your Orange ID and password to access the Flexible Engine console. For more information visit Orange Cloud.

You should be able to log in to the Orange Cloud Customer space (https://selfcare.cloud.orange-business.com/) with the credentials provided to you with your Orange Cloud account. You will also be provided with a domain name when you sign up for your Orange Cloud account.

5.5.2 Create an Orange Cloud Flexible Engine User Account

PBS Cloud will use an Orange Cloud user account to manage cloud nodes. Make sure that you collect the following information while you are creating the user account (we will also remind you):

Table 5-7: Account Parameters for Orange

Account Parameter	What to Collect During Configuration at Vendor	Format
Auth URL	*https://iam.<orange region>.<console link>*	String
User Domain Name	Orange ID used to log in to Orange account. Same as domain name.	String
Username	Administrator username created at vendor	String
Password	API password generated at vendor	String

1. Go to the Orange Cloud Customer space login page.
2. Enter your Orange Cloud credentials.
3. Click Your services.

Figure 5-21:Orange Cloud Customer Space Services

4. In the navigation bar on the top click Users
5. Click Add user.
6. Enter the following user details:
   a. For Civility, choose the form of address
   b. For Last name, enter the user's last name.
   c. For First name, enter the user's first name.
   d. For Login, enter a login name for the user.
   e. For Email, enter the user's email address.
   f. For Phone number, enter the user's phone number.
   g. For Mobile phone, enter the user's mobile phone number.
   h. For Preferred language, choose the language in which the application should be displayed.
   i. Click next.

7. In the Roles section enter these details:
   a. For Billing, choose Visitor.
   b. For Contracts, choose Account Manager.
   c. For Dashboard, choose Visitor.
   d. For Documents, choose Visitor.
   e. For Orders, choose Visitor.
   f. For Services, choose Visitor.
   g. For Subscriptions, choose Visitor.
   h. For Support, choose Visitor.
   i. For Users, choose Manager.
   j. For Flexible Engine Console, choose admin.
   k. Click next.
8. In the Summary section review your choices. Click previous to edit your choices.
9. Click finish.

   The new user account is created and displayed in the list of users. Emails are sent to the email address you specified. The emails will contain:
   - Orange ID (Domain Name). This is the administrator username PBS Cloud will use to manage cloud nodes.
   - Link to set Orange Password. This password is for the administrator to log into Web interface.
   - Link to access Cloud Customer Space.
   - Link to log in to the Flexible Engine Console.
   - Link to define your API password. This password is used by the administrator account for making API requests; PBS Cloud will use this to make API requests.
10. Click the link in the email to set your Orange Password.
11. Click the link in the email to set your API Password.
12. **Store the API Password to a file**. The API Password is used later to create a cloud account in PBS Cloud.

5.5.3 Select a Region

Define a region in the Orange Cloud Flexible Engine console to set up the infrastructure for cloud bursting.

A region is a geographic area where resources used by your ECSes are located. ECSes in the same region can communicate with each other over an intranet, but ECSes in different regions cannot. Before setting up the infrastructure for cloud bursting, it is important to ensure that all the resources are defined in the same region. An Authorization URL is required for adding the Orange Cloud Flexible Engine cloud account in PBS Cloud. This is based on the region selected.

1. Log in to the Orange Cloud Flexible Engine console.
2. In the navigation bar on the top, pull down the region menu and select the region for setting up your infrastructure.
3. For the Authorization URL, (IAM URL), enter the URL in the following format based on the region you chose in the Orange Cloud Flexible Engine console:

   https://iam.<orange region>.<console link>

   e.g. `https://iam.eu-west-0.prod-cloud-ocb.orange-business.com`
4. **Store the region and Auth (IAM) URL in a file**. You will use these to add the provider cloud account to PBS Cloud.

5.5.4 Check Orange Cloud Flexible Engine Account Service Quota

Quotas are used to limit the number of resources available to users. It is important to ensure you are not exceeding your quota while setting up the resources for cloud bursting. If the existing resource quota cannot meet your service requirements, you can submit a work order to increase your quota. Once your application is approved, Orange Cloud Flexible Engine will update your resource quota accordingly and send you a notification.

1. Log in to the Orange Cloud Flexible Engine console.
2. In the navigation bar on the top right hand side, click 

   Information about resources usage and availability is displayed.

5.5.5 Create a Virtual Private Cloud

Orange Cloud Flexible Engine documentation for VPC can be found at:Virtual Private Cloud Documentation

1. Log in to the Orange Cloud Flexible Engine console.
2. In the top navigation bar select the region where you wish to deploy your cloud infrastructure.
3. From the Network section click Virtual Private Cloud.
4. Click + Create VPC.
5. In the Basic Information section:
   a. For Region, ensure the VPC is the same region as the other resources.
   a. For Name, enter a name for the VPC.
   a. For CIDR Block, enter CIDR values for the VPC.
6. In the Subnet Settings section:
   a. For the Subnet Settings choose the AZ (Availability Zone) as the same as the region.
   b. For Subnet Name, enter a name to match the VPC Name.
   c. Enter CIDR Block for Subnet.
   d. For Advanced Settings, click Default.
7. Review the Configuration information.
8. Click Create Now.
9. Once the VPC is created, click the Back to VPC List.
10. Click Security Group in the left hand side menu.
11. Click + Create Security Group.
12. For Name, enter a name for the Security Group.
13. For Description, enter a suitable Description.
14. Click OK
15. By default, the Outbound and Inbound traffic over IPv4 is open. You can add firewall rules to this security group if required.

5.5.6 Creating a Virtual Machine

1. Log in to the Orange Cloud Flexible Engine console.
2. In the Computing section and click Elastic Cloud Server.
3. From the menu on the left hand side click Key Pair.
4. Click + Create Key Pair.
5. Enter a Name for the Key Pair.
6. Click OK.
7. Save the Key Pair (.pem) file to your local disk in a secure location. The information in this .pem file is used later to SSH into the VM.
8. Click OK to confirm that you have downloaded the Key Pair file.
9. From the menu on the left hand side, click Elastic Cloud Server.
10. Click + Create ECS.
11. For Region, click the region you selected for setting up the infrastructure.
12. For AZ (Availability Zone), select the AZ related to the region.
13. In the Specifications section:
    a. For ECS type, click one of the flavor names. Orange Cloud Flexible Engine provides a set of predefined ECS types for specific requirements. Click a flavor name to get the list of available configurations.
    b. Review the specifications you have selected.
14. In the Image section:
    a. Click Public image.
    b. From the drop down menu select CentOS
    c. From the version drop down menu select Select OBS_U_CentOS_7.2(40GB)
15. In the Disk section select the defaults.
16. In the VPC section:
    a. For VPC, select the VPC you created from the drop down menu.
    a. For NIC, choose the default primary NIC.
    b. For Security Group, select the Security Group you created for the VPC.
    c. For EIP, click Automatically assign
    d. For Bandwidth, specify it as 5 Mbit/s.
17. For Login Mode, select the Key Pair you generated earlier from the drop down menu.
18. For Auto Recovery, click Enable.
19. For Advanced Settings, click Do not configure.
20. For ECS Name, enter a name.
21. For Quantity, specify 1.
22. Review the Current Configuration.
23. Click Create Now.

24. Review the Specifications.
25. Click Submit.

    The ECS (Virtual Machine) is created and displayed in the list of ECS.

5.5.7 Installing and Configuring a PBS MoM on the VM

1. Log in to your site's PBS Server.
2. Log in to the Flexible Engine console.
3. In the Computing section, click Elastic Cloud Server.
4. In the search box above the upper right corner of the ECS list, enter the ECS name, IP address, or ID, and click the search icon.
5. Click the name of the target ECS.
6. The page providing details about the ECS is displayed.
7. Copy the Public IP address (External IP) of the ECS.
8. SSH into the VM using the default user "cloud", the .pem file you generated when creating the VM, and the External IP assigned to the VM. For more information about logging into the Linux ECS, refer to the Elastic Cloud Server User Guide.

   ssh -i /<path to .pem file>/<name of .pem file>.pem cloud@<public IP address of VM>
9. Switch to root:

   sudo -i
10. Using the PBS Professional Installation and Upgrade Guide, install and configure the PBS MOM.
11. Save the file.
12. Configure the VM to work with your site environment, for example mounting file systems, connecting to the authentication service, installing any applications you need, etc. We recommend that you include the following:
    - Mount `/home` in the VM
    - Either install applications in the VM or cross-mount them from the PBS server host
    - Either add users to the password file or connect the VM to a service such as NIS
13. If `cloud-init` is not installed, install it.

5.5.8 Add Authentication and Encryption

5.5.8.1 Add Authentication via MUNGE

Configure your instance to use MUNGE to authenticate users and daemons.

To configure authentication on the instance that you will use as your image source, use MUNGE:

1. Log in as root
2. Download and install a supported version of MUNGE. You can get MUNGE either via your Linux distribution package repositories or from the MUNGE project directly.

   Follow the MUNGE installation instructions at https://github.com/dun/munge/wiki/Installation-Guide.
3. On the PBS server host, generate the `munge.key` file using the `create-munge-key` command.

4. On every host, if the library name is not exactly "libmunge.so", for example "libmunge.so.2", add a soft link to it. For example:

   ```
   ln -s /lib64/libmunge.so.2 /lib64/libmunge.so
   ```

5. Copy /etc/munge/munge.key from the PBS server host to the source instance:

   ```
   # scp $PBS_SERVER:/etc/munge/munge.key /etc/munge/munge.key
   ```

6. Start MUNGE:

   ```
   systemctl start munge
   ```

7. Make sure that on the PB server host, the PBS configuration file (/etc/pbs.conf) contains these lines:

   ```
   PBS_AUTH_METHOD=MUNGE
   PBS_SUPPORTED_AUTH_METHODS="pwd,munge"
   ```

8. On your source instance that you will use to burst nodes, edit the PBS configuration file (/etc/pbs.conf) and add this line:

   ```
   PBS_AUTH_METHOD=MUNGE
   ```

9. Restart the PBS MoM:

   ```
   systemctl restart pbs
   ```

For information about configuring encryption for PBS Professional, see "Authentication for Daemons & Users" on page 508 in the PBS Professional Administrator's Guide.

5.5.8.2 Add Encryption via TLS

Configure your instance to use TLS to encrypt communication.

To configure encryption on the instance that you will use as your image source, use TLS:

1. Log in as root
2. Edit PBS configuration file pbs.conf, and set the PBS_ENCRYPT_METHOD parameter:

   ```
   PBS_ENCRYPT_METHOD=tls
   ```

3. Make it so we can use the value of PBS_HOME in pbs.conf:

   ```
   # source /etc/pbs.conf
   ```

4. Create certificate directory PBS_HOME/certs:

   ```
   # mkdir ${PBS_HOME}/certs
   ```

5. Copy files from the PBS server host certificate directory into the VM certificate directory:
   a. Copy your cert.pem file to ${PBS_HOME}/certs/cert.pem:

      ```
      # scp $PBS_SERVER:${PBS_HOME}/certs/cert.pem ${PBS_HOME}/certs/cert.pem
      ```

   b. Copy your key.pem file to ${PBS_HOME}/certs/key.pem:

      ```
      # scp $PBS_SERVER:${PBS_HOME}/certs/key.pem ${PBS_HOME}/certs/key.pem
      ```

6. Set permissions and ownership for certificate directory:
   a. Make sure that permissions for the certificate directory and its contents are *0600:*

      ```
      # chmod -R 0600 ${PBS_HOME}/certs
      ```

   b. Make sure the owner is root on Linux or Administrator on Windows:

      ```
      # chown -R root: ${PBS_HOME}/certs
      ```

7. Restart PBS MoM:
   - On every Linux host in the complex:
     ```
     # <path to start/stop script>/pbs restart
     ```
     or
     ```
     # systemctl start pbs
     ```
   - On every Windows execution host in the complex:
     ```
     net stop pbs_mom
     net start pbs_mom
     ```

For information about configuring encryption for PBS Professional, see "Encrypting PBS Communication" on page 517 in the PBS Professional Administrator's Guide.

5.5.9 Create an OS Image

Orange Cloud Flexible Engine documentation can be found at Creating a Linux Private Image Using an ECS.

5.5.9.1 Prerequisites

Before creating the Image from the ECS, you must have.

- A Linux ECS in the Stopped state.
- Configured DHCP for the NICs of the ECS
- Configured Network attributes of the ECS
- Detached Data Disks from the ECS

5.5.9.2 Steps to Create OS Image

1. Log in to the Flexible Engine console.
2. In the Computing section, click Image Management Service.
3. On the Image Management Service page, click + Create Private Image.
4. In the Image Type and Source section, .
   a. For Type, click System disk image
   b. For Source, click ECS
   c. Select the target ECS from the ECS list.
5. Set the required information, such as Name and Description.
6. Click Create Now.
7. Confirm the parameters and click Submit.
8. Switch back to the Image Management Service page to view the image status.

   The time required for creating an image varies depending on the image file size. Generally, it takes about 20 minutes to create an image. The image is successfully created when its image status changes to Normal.

   Do not perform any operation on the selected ECS or its associated resources during image creation.
9. You can delete the virtual machine now to avoid storage costs, or keep the virtual machine and update it over time to create updated OS images for bursting. You will incur storage costs, but this is an effective way to keep your OS images up to date when there are changes in packages, patches, or applications.

5.5.10 Create Orange Cloud Cloud Bursting Scenario

5.5.10.1 Scenario Parameters to Collect at Vendor Interface

Make sure that you capture the following scenario parameters. We will remind you about them:

Table 5-8: Scenario Parameters for Orange

Scenario Parameter	What to Collect During Configuration at Vendor	Format
Cloud account	Name of your administrator account at cloud vendor	String
Region	Region selected during configuration at cloud vendor	Drop-down list
Domain name	Domain used by cloud nodes	String
Hostname prefix	Optional prefix for burst node names; default is "node"; chosen during configuration at vendor	String
Subnet ID	ID of subnet for VPC created at cloud vendor	String
Security Group ID	ID of security group created at cloud vendor	String
OS Image URI	ID of OS image created at cloud vendor	String

5.5.10.2 Steps to Collect Information

Open a browser window and log in to the Orange Cloud Flexible Engine console.

10. Click Service List in the menu bar.

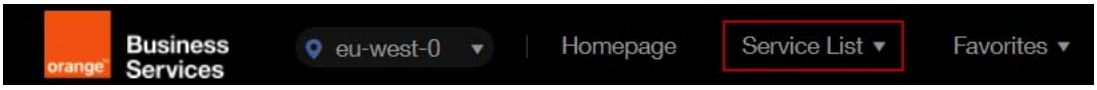

Figure 5-22:Orange Cloud Flexible Engine Console

11. Under Network, click Virtual Private Cloud.
12. Click Virtual Private Cloud from the menu located on the left-hand side of the web page.
13. Click the name of the VPC you created for cloud bursting.
14. Click the name of the Subnet for the VPC.
15. Copy the Subnet ID.
16. **Save the subnet ID to a file**. You will need this later when you create a bursting scenario.
17. Click Security Group from the left hand side menu.
18. Click the name of the Security Group you created for the VPC.
19. Copy the ID of the Security Group.
20. **Save the security group to a file**. You will need this later when you create a bursting scenario.
21. Click Service List in the menu bar.
22. Under Computing, click Image Management Service.
23. Click the Private Images tab.
24. Click the name of the VM image you created for cloud bursting.

25. Copy the ID of the image.
26. **Save the OS Image ID to a file**. You will need this later when you create a bursting scenario.

5.6 Configuring HUAWEI Cloud for Cloud Bursting

5.6.1 Create and Activate HUAWEI Account

Create and activate a HUAWEI Cloud account.

5.6.2 Get the HUAWEI Cloud Administrator Credentials

PBS Cloud will use the HUAWEI Cloud administrative user account to manage cloud nodes. While you are getting the credentials for the administrative user account, make sure you capture the following information:

Table 5-9: Account Parameters for Huawei

Account Parameter	What to Collect During Configuration at Vendor	Format
Auth URL	*https://iam.ap-southeast-1.myhwclouds.com*	String
User Domain Name	Domain Name provided when your subscription to HUAWEI Cloud was created If you do not know your Domain name, contact HUAWEI Cloud support.	String
Username	Administrator username created at vendor	String
Password	Administrator password created at vendor	String

5.6.2.1 Choose Administrative User

You can create a new user and give the user administrative privileges, or you can use the administrative user account that is automatically created when you subscribe to HUAWEI Cloud.

The automatically-created user is an administrative user account with permissions for all system operations.

If you create a new user, give the user administrative privileges by setting its User Group to "admin".

5.6.2.2 Get Credentials

1. Log in to the HUAWEI Cloud Console.
2. Click Service List.

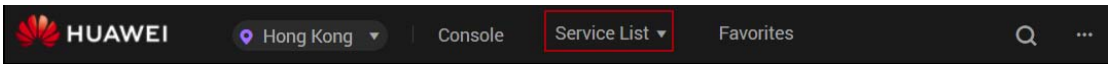

Figure 5-23:HUAWEI Cloud Console

3. Under Management & Deployment, click Identity and Access Management.
4. Click Users from the menu located on the left-hand side of the web page. A list of users is displayed.
5. Click the down-arrow located next to a username to display the user's details.

The user account listed as an "admin" is the account to use to create the cloud account in PBS Cloud.

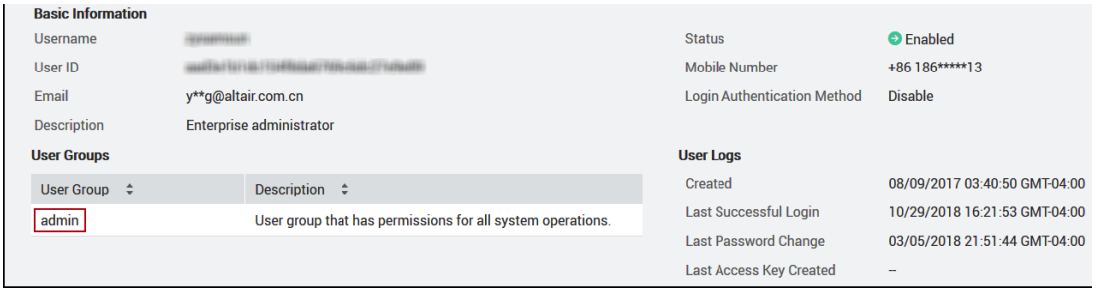

Figure 5-24:User Details

6. If you do not know the password for the administrative user account, click Set Credentials.

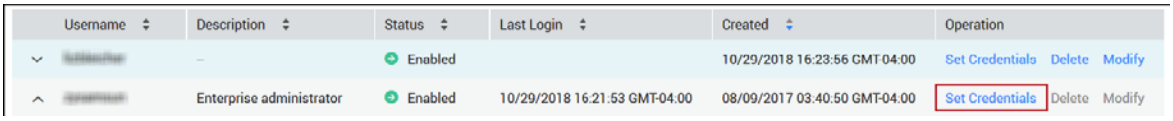

Figure 5-25:Set Password

a. Enable Set manually.

b. For Password, enter a password for the user account.

c. For Confirm Password, enter the password a second time.

d. **Save the password**. You will need this later when you add the administrative user account to PBS Cloud.

e. Click OK.

You may have to confirm the password change either by email or by a SMS text.

5.6.3 Check HUAWEI Cloud Account Service Quotas

View your OTC account resource usage and limits.

Quotas are used to limit the number of resources available to users. It is important to ensure you are not exceeding your quota while setting up the resources for cloud bursting. If the existing resource quota cannot meet your service requirements, you can submit a work order to increase your quota. Once your application is approved, HUAWEI Cloud will update your resource quota accordingly and send you a notification.

1. Log in to the HUAWEI Cloud console.
2. Click Resources > My Quota.

Information about resources usage and availability is displayed.

5.6.4 Create a Virtual Private Cloud

HUAWEI Cloud documentation for creating a VPC can be found at: Creating a VPC and Regions and AZs.

1. Log in to the HUAWEI Cloud Console.
2. Click Service List in the menu bar.
3. Under Network, click Virtual Private Cloud.
4. Click + Create VPC.

5. In the Basic Information section:
   a. For Region, select a region.

      Regions are geographic areas isolated from each other. Resources are region-specific and cannot be used across regions through internal network connections. For low network latency and quick resource access, select the nearest region.

   b. For Name, enter a name for the VPC.
   c. For CIDR Block, enter an address range for the network using CIDR notation.
6. In the Subnet Settings section:
   a. For the Subnet Settings choose the AZ (Availability Zone).

      An Availability Zone is a physical location where resources use independent power supplies and networks. AZs are physically isolated and AZs in the same VPC are interconnected through an internal network.

   b. For Subnet Name, enter a name for the subnet.
   c. For CIDR, enter an address range for the subnet using CIDR notation.
   d. For Advanced Settings, click Default.
7. Click Create Now.
8. Click Back to VPC List.
9. Click Security Group in the left hand side menu.
10. Click + Create Security Group.
11. For Name, enter a name for the security group.
12. For Description, enter a suitable description.
13. Click OK.
14. By default, the Outbound and Inbound traffic over IPv4 is open. You can add firewall rules to this security group if required.

5.6.5 Creating a Virtual Machine

HUAWEI Cloud documentation for creating an ECS (virtual machine) can be found at Purchase an ECS.

1. Log in to the HUAWEI Cloud Console.
2. Click Service List in the menu bar.
3. Under Computing, click Elastic Cloud Server.
4. Click Key Pair from the menu located on the left-hand side of the web page.
5. Click + Create Key Pair.
6. For Name, enter a name for the key pair.
7. Click OK.
8. Save the key pair (.pem) file to your local disk in a secure location. The information in this .pem file is used later to SSH into the VM.
9. Click OK to confirm that you have downloaded the key pair file.
10. Click Elastic Cloud Server from the menu located on the left-hand side of the web page.
11. Click Buy ECS.

12. For Billing Mode, click Pay-per-use.
13. For Region, select the same region that was chosen for the previously created VPC.
14. For AZ (Availability Zone), select the same AZ that was chosen for the previously created VPC.
15. In the Type section:
    a. Choose an ECS type category:
       - General computing
       - General computing-plus
       - Memory-optimized
       - Large-memory
       - High-performance computing
       - Disk-intensive
    b. For ECS type, click one of the flavor based on the needs of your site.
16. In the Image section:
    a. Click Public image.
    b. For Select an OS, select CentOS.
    c. For Select an OS version, select CentOS 7.2 64bit(40GB).
17. In the Disk section, select your system disk requirements.
18. In the VPC section:
    a. For VPC, select the VPC you created for cloud bursting. The NIC information is automatically populated.
    b. For Security Group, select the security group you created for cloud bursting.
    c. For EIP, click Automatically assign
    d. For Bandwidth, specify it as 5 Mbit/s.
19. For Login Mode, select Key Pair.
20. For Key Pair, select the key pair file you generated earlier.
21. For Advanced Settings, click Not required.
22. For ECS Name, enter a name for the virtual machine.
23. For Quantity, specify 1.
24. Click Next.
25. Review the specifications.
26. Enable the I have read and agree to the Huawei Image Disclaimer checkbox.
27. Click Submit Application.
28. Click Back to ECS List.

    It may take some time to create the virtual machine. Once the ECS is created it is displayed in the ECS list.

5.6.6 Installing and Configuring a PBS MoM on the VM

1. Log in to the HUAWEI Cloud console.
2. Click Service List in the menu bar.

3. Under Computing, click Elastic Cloud Server.
4. Copy the Public IP address (External IP) of the ECS.

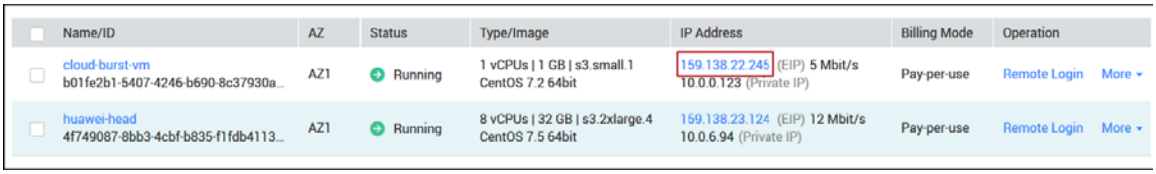

Figure 5-26:VM IP Address

5. Log in to your site's PBS Server.
6. SSH into the VM using the default user "root", the .pem file you generated when creating the VM and the External IP assigned to the VM.

   ```
   sh -i /path/my-key-pair.pem root@IPV4PublicIP
   ```

   where /path/my-key-pair.pem is the path to the .pem file downloaded while creating the virtual machine and IPV4PublicIP is the public IP address of the virtual machine.
7. Using the PBS Professional Installation and Upgrade Guide, install and configure the PBS MOM.
8. Configure the VM to work with your site environment, for example mounting file systems, connecting to the authentication service, installing any applications you need, etc. We recommend that you include the following:
   - Mount `/home` in the VM
   - Either install applications in the VM or cross-mount them from the PBS server host
   - Either add users to the password file or connect the VM to a service such as NIS
9. If `cloud-init` is not installed, install it.

5.6.7 Add Authentication and Encryption

5.6.7.1 Add Authentication via MUNGE

Configure your instance to use MUNGE to authenticate users and daemons.

To configure authentication on the instance that you will use as your image source, use MUNGE:

1. Log in as root
2. Download and install a supported version of MUNGE. You can get MUNGE either via your Linux distribution package repositories or from the MUNGE project directly.

   Follow the MUNGE installation instructions at https://github.com/dun/munge/wiki/Installation-Guide.
3. On the PBS server host, generate the `munge.key` file using the `create-munge-key` command.
4. On every host, if the library name is not exactly "libmunge.so", for example "libmunge.so.2", add a soft link to it. For example:

   ```
   ln -s /lib64/libmunge.so.2 /lib64/libmunge.so
   ```
5. Copy `/etc/munge/munge.key` from the PBS server host to the source instance:

   ```
   # scp $PBS_SERVER:/etc/munge/munge.key /etc/munge/munge.key
   ```
6. Start MUNGE:

   ```
   systemctl start munge
   ```

7. Make sure that on the PB server host, the PBS configuration file (/etc/pbs.conf) contains these lines:

   ```
   PBS_AUTH_METHOD=MUNGE
   PBS_SUPPORTED_AUTH_METHODS="pwd,munge"
   ```

8. On your source instance that you will use to burst nodes, edit the PBS configuration file (/etc/pbs.conf) and add this line:

   ```
   PBS_AUTH_METHOD=MUNGE
   ```

9. Restart the PBS MoM:

   ```
   systemctl restart pbs
   ```

For information about configuring encryption for PBS Professional, see "Authentication for Daemons & Users" on page 508 in the PBS Professional Administrator's Guide.

5.6.7.2 Add Encryption via TLS

Configure your instance to use TLS to encrypt communication.

To configure encryption on the instance that you will use as your image source, use TLS:

1. Log in as root
2. Edit PBS configuration file pbs.conf, and set the PBS_ENCRYPT_METHOD parameter:

   ```
   PBS_ENCRYPT_METHOD=tls
   ```

3. Make it so we can use the value of PBS_HOME in pbs.conf:

   ```
   # source /etc/pbs.conf
   ```

4. Create certificate directory PBS_HOME/certs:

   ```
   # mkdir ${PBS_HOME}/certs
   ```

5. Copy files from the PBS server host certificate directory into the VM certificate directory:
   a. Copy your cert.pem file to ${PBS_HOME}/certs/cert.pem:

      ```
      # scp $PBS_SERVER:${PBS_HOME}/certs/cert.pem ${PBS_HOME}/certs/cert.pem
      ```

   b. Copy your key.pem file to ${PBS_HOME}/certs/key.pem:

      ```
      # scp $PBS_SERVER:${PBS_HOME}/certs/key.pem ${PBS_HOME}/certs/key.pem
      ```

6. Set permissions and ownership for certificate directory:
   a. Make sure that permissions for the certificate directory and its contents are *0600:*

      ```
      # chmod -R 0600 ${PBS_HOME}/certs
      ```

   b. Make sure the owner is root on Linux or Administrator on Windows:

      ```
      # chown -R root: ${PBS_HOME}/certs
      ```

7. Restart PBS MoM:
   - On every Linux host in the complex:

     ```
     # <path to start/stop script>/pbs restart
     ```

     or

     ```
     # systemctl start pbs
     ```

   - On every Windows execution host in the complex:

     ```
     net stop pbs_mom
     net start pbs_mom
     ```

For information about configuring encryption for PBS Professional, see "Encrypting PBS Communication" on page 517 in the PBS Professional Administrator's Guide.

5.6.8 Create an OS Image

HUAWEI Cloud documentation can be found at Creating a Linux Private Image.

1. Log in to the HUAWEI Cloud console.
2. Click Service List in the menu bar.
3. Under Computing, click Image Management Service.
4. Click + Create Image.
5. For Region, select the same region that was chosen for the previously created VPC and ECS.
6. In the Image Type and Source section, .
   a. For Type, click System disk image.
   b. For Source, click ECS.
   c. Select the virtual machine created for cloud bursting.
   d. For Name, enter a name for the virtual machine.
7. Click Next.
8. Review the specifications.
9. Enable the I have read and agree to the Statement of Commitment to Image Creation and Huawei Image Disclaimer checkbox.
10. Click Submit.
11. Click Back to Image List.

    The time required for creating an image varies depending on the image file size. Generally, it takes about 20 minutes to create an image. The image is successfully created when its image status changes to Normal.

    Do not perform any operation on the selected ECS or its associated resources during image creation.
12. You can delete the virtual machine now to avoid storage costs, or keep the virtual machine and update it over time to create updated OS images for bursting. You will incur storage costs, but this is an effective way to keep your OS images up to date when there are changes in packages, patches, or applications.

5.6.9 Collect HUAWEI Cloud Bursting Scenario Information

5.6.9.1 Scenario Parameters to Collect at Vendor Interface

Make sure that you capture the following scenario parameters. We will remind you about them:

Table 5-10: Scenario Parameters for Huawei

Scenario Parameter	What to Collect During Configuration at Vendor	Format
Cloud account	Name of your account at cloud vendor	String
Region	Region selected during configuration at cloud vendor	Drop-down list
Domain name	Domain used by cloud nodes	String
Hostname prefix	Optional prefix for burst node names; default is "node"; chosen during configuration at vendor	String
Subnet ID	ID of subnet for VPC created at cloud vendor	String
Security Group ID	ID of security group created at cloud vendor	String
OS Image URI	ID of OS image created at cloud vendor	String

5.6.9.2 Steps to Collect Information

Open a browser window and log in to the HUAWEI Cloud console.

13. Click Service List in the menu bar.
14. Under Network, click Virtual Private Cloud.
15. Click Virtual Private Cloud from the menu located on the left-hand side of the web page.
16. Click the name of the VPC you created for cloud bursting.
17. Click the name of the VPC's subnet.
18. Copy the Subnet ID.
19. **Save the subnet ID to a file**. You will need this later when you create a bursting scenario.
20. Click Security Group from the menu located on the left-hand side of the web page.
21. Click the name of the security group you created for the VPC.
22. Copy the ID of the security group.
23. **Save the security group to a file**. You will need this later when you create a bursting scenario.
24. Click Service List in the menu bar.
25. Under Computing, click Image Management Service.
26. Click the Private Images tab.
27. Click the name of the VM image you created for cloud bursting.
28. Copy the ID of the image.
29. **Save the OS Image ID to a file**. You will need this later when you create a bursting scenario.

5.7 Configuring Open Telekom Cloud for Cloud Bursting

5.7.1 Create and Activate OTC Cloud Account

Create and activate an OTC Cloud account.

5.7.2 Obtain the OTC Administrator Credentials

PBS Cloud will use the OTC administrative user account to manage cloud nodes. While you are getting the credentials for the administrative user account, make sure you capture the following information:

Table 5-11: Account Parameters for Deutsche Telekom OTC

Account Parameter	What to Collect During Configuration at Vendor	Format
Auth URL	*https://iam.eu-de.otc.t-systems.com/v3*	String
User Domain Name	Deutsche Telekom: OTC domain name used to log in to OTC console at vendor	String
Username	Administrator username created at vendor	String
Password	Administrator password created at vendor	String

5.7.2.1 Choose Administrative User

You can create a new user and give the user administrative privileges, or you can use the administrative user account that is automatically created when you subscribe to OTC.

The automatically-created user is an administrative user account with permissions for all system operations.

If you create a new user, give the user administrative privileges by setting its User Group to "admin".

5.7.2.2 Get Credentials

1. Log in to the OTC Console.
2. Click Service List in the menu bar.
3. Under Management & Deployment, click Identity and Access Management.
4. Click Users from the menu located on the left-hand side of the web page. A list of users is displayed.
5. Click the down-arrow located next to a username to display the user's details.

The user account listed as an "admin" is the account to use to create the cloud account in PBS Cloud.

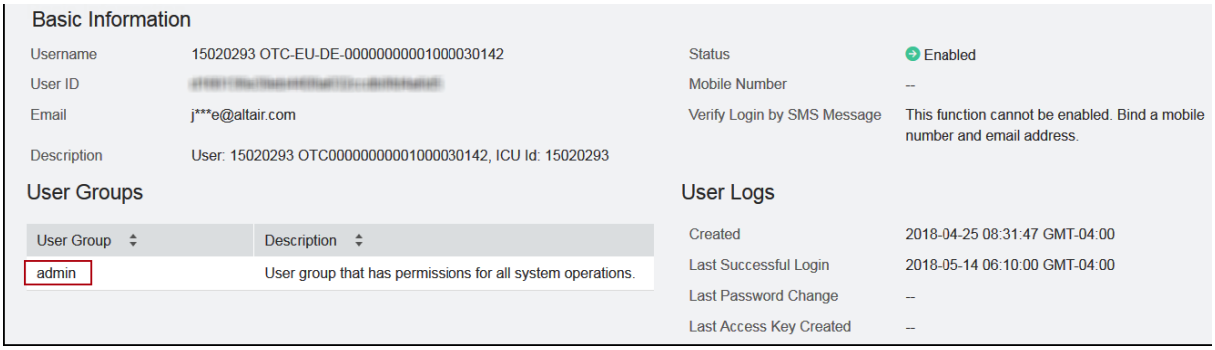

Figure 5-27:User Details

6. If you do not know the password for the admin user account, click Set Credentials

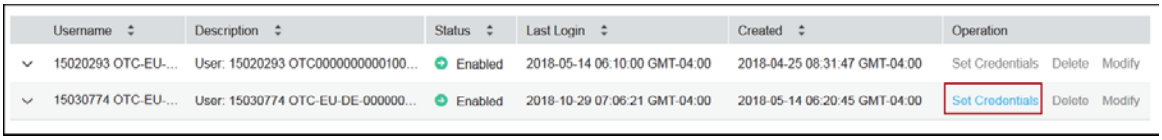

Figure 5-28:Set Password

7. Enable Set manually.
8. For Password, enter a password for the user account.
9. For Confirm Password, enter the password a second time.
10. Click OK.

    You may have to confirm the password change either by email or by a SMS text.

5.7.3 Check OTC Account Service Quotas

Quotas are used to limit the number of resources available to users. It is important to ensure you are not exceeding your quota while setting up the resources for cloud bursting. If the existing resource quota cannot meet your service requirements, you can submit a work order to increase your quota. Once your application is approved, OTC will update your resource quota accordingly and send you a notification.

1. Log in to the OTC Console.
2. Click the three vertical bars in the menu bar:

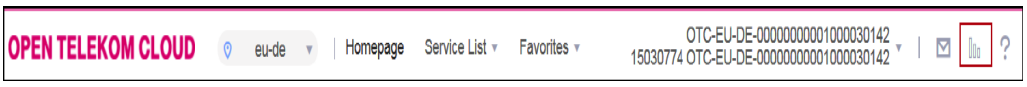

Figure 5-29:Viewing Quotas

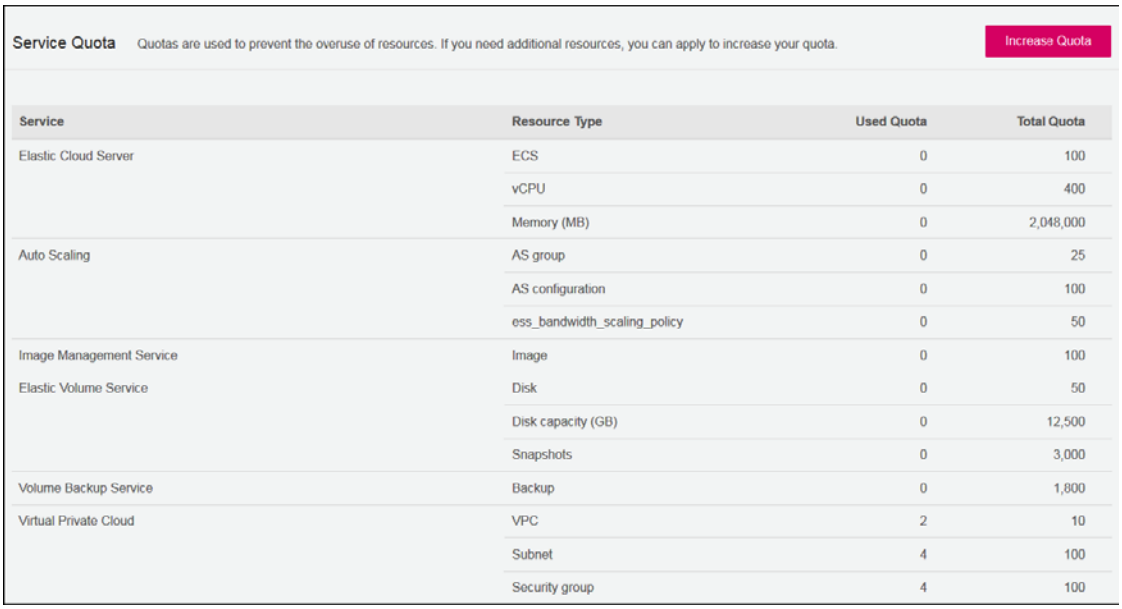
You can see resource usage and availability:



Service Quota Quotas are used to prevent the overuse of resources. If you need additional resources, you can apply to increase your quota. Increase Quota

Service	Resource Type	Used Quota	Total Quota
Elastic Cloud Server	ECS	0	100
	vCPU	0	400
	Memory (MB)	0	2,048,000
Auto Scaling	AS group	0	25
	AS configuration	0	100
	ess_bandwidth_scaling_policy	0	50
Image Management Service	Image	0	100
Elastic Volume Service	Disk	0	50
	Disk capacity (GB)	0	12,500
	Snapshots	0	3,000
Volume Backup Service	Backup	0	1,800
Virtual Private Cloud	VPC	2	10
	Subnet	4	100
	Security group	4	100

Figure 5-30:Resource quotas and availability

5.7.4 Create a Virtual Private Cloud

OTC documentation for creating a VPC can be found at: Creating a VPC and Regions.

1. Log in to the OTC Console.
2. Click Service List.
3. Under Network, click Virtual Private Cloud.
4. Click + Create VPC.
5. In the Basic Information section:
   a. For Region, select a region.

OPEN TELEKOM CLOUD eu-de Homepage Service List Favorites

Figure 5-31:Regions

   A region is a geographical areas and can comprise one or more availability zones (AZs). A region is completely isolated from other regions. Only AZs in the same region can communicate with one another through an internal network.

   b. For Name, enter a name for the VPC.
   c. For CIDR Block, enter an address range for the network using CIDR notation.
6. In the Subnet Settings section:
   a. For Subnet Name, enter a name for the subnet.
   b. For CIDR, enter an address range for the subnet using CIDR notation.
   c. For Advanced Settings, click Default.
7. Click Create Now.
8. Click Back to VPC List.

9. Click Security Group in the left hand side menu.
10. Click + Create Security Group.
11. For Name, enter a name for the security group.
12. For Description, enter a suitable description.
13. Click OK.

    The security group rules are displayed.
14. Click the Inbound tab.
15. Click Add Rule.
    a. For Protocol/Application, select TCP.
    b. For Port, enter 22.
    c. For Source, select IP Address. and enter the PBS Cloud firewall IP address.
    d. Click OK.

5.7.5 Creating a Virtual Machine

OTC documentation for creating an ECS (virtual machine) can be found at Create an ECS.

1. Log in to the OTC Console.
1. Click Service List in the menu bar.
2. Under Computing, click Elastic Cloud Server.
3. Click Key Pair from the menu located on the left-hand side of the web page.
4. Click + Create Key Pair.
5. For Name, enter a name for the key pair.
6. Click OK.
7. Save the key pair (.pem) file to your local disk in a secure location. The information in this .pem file is used later to SSH into the VM.
8. Click OK to confirm that you have downloaded the key pair file.
9. Click Elastic Cloud Server from the menu located on the left-hand side of the web page.
10. Click Create ECS.
11. For Region, select the same region that was chosen for the previously created VPC.
12. For AZ (Availability Zone), select an availability zone.

13. In the Specifications section:
    a. Choose an ECS type category:
        - General-purpose
        - Dedicated general-purpose
        - Memory-optimized
        - Large-memory
        - High-performance
        - Disk-intensive
        - GPU-accelerated
    b. For ECS type, choose one of the flavors based on the needs of your site.
14. In the Image section:
    a. Click Public image.
    b. Select a supported OS as the operating system.
    c. Select a supported version of the OS.
15. In the Disk section, select your system disk requirements.
16. In the VPC section:
    a. For VPC, select the VPC you created for cloud bursting. The NIC information is automatically populated.
    b. For Security Group, select the security group you created for cloud bursting.
    c. For EIP, click Automatically assign
    d. For Bandwidth, specify it as 5 Mbit/s.
17. For Log in Mode, select Key Pair.
18. For Key Pair, select the key pair file you generated earlier.
19. For Advanced Settings, click Do not configure.
20. For ECS Name, enter a name for the virtual machine.
21. For Quantity, specify 1.
22. Click Create Now.
23. Review the specifications.
24. Click Submit.
25. Click Back to ECS List.

    It may take some time to create the virtual machine. Once the ECS is created it is displayed in the ECS list.

5.7.6 Installing and Configuring a PBS MoM on the VM

1. Log in to the OTC Console.
2. Click Service List in the menu bar.
3. Under Computing, click Elastic Cloud Server.

4. Copy the Public IP address (External IP) of the ECS.

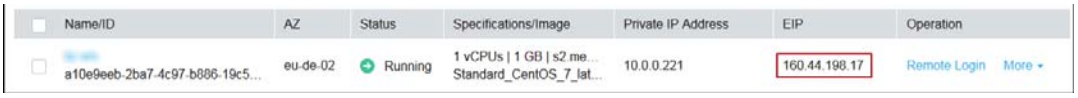


Figure 5-32:VM IP Address

5. Log in to your site's PBS Server.
6. SSH into the VM using the default user "root", the .pem file you generated when creating the VM and the External IP assigned to the VM.

   ssh -i /path/my-key-pair.pem root@IPV4PublicIP

   where /path/my-key-pair.pem is the path to the .pem file downloaded while creating the virtual machine and IPV4PublicIP is the public IP address of the virtual machine.
7. Using the PBS Professional Installation and Upgrade Guide, install and configure the PBS MOM.
8. Configure the VM to work with your site environment, for example mounting file systems, connecting to the authentication service, installing any applications you need, etc. We recommend that you include the following:
   - Mount /home in the VM
   - Either install applications in the VM or cross-mount them from the PBS server host
   - Either add users to the password file or connect the VM to a service such as NIS
9. If `cloud-init` is not installed, install it.

5.7.7 Add Authentication and Encryption

5.7.7.1 Add Authentication via MUNGE

Configure your instance to use MUNGE to authenticate users and daemons.

To configure authentication on the instance that you will use as your image source, use MUNGE:

1. Log in as root
2. Download and install a supported version of MUNGE. You can get MUNGE either via your Linux distribution package repositories or from the MUNGE project directly.

   Follow the MUNGE installation instructions at https://github.com/dun/munge/wiki/Installation-Guide.
3. On the PBS server host, generate the munge.key file using the `create-munge-key` command.
4. On every host, if the library name is not exactly "libmunge.so", for example "libmunge.so.2", add a soft link to it. For example:

   ln -s /lib64/libmunge.so.2 /lib64/libmunge.so
5. Copy /etc/munge/munge.key from the PBS server host to the source instance:

   # scp $PBS_SERVER:/etc/munge/munge.key /etc/munge/munge.key
6. Start MUNGE:

   systemctl start munge
7. Make sure that on the PB server host, the PBS configuration file (`/etc/pbs.conf`) contains these lines:

   ```
   PBS_AUTH_METHOD=MUNGE
   PBS_SUPPORTED_AUTH_METHODS="pwd,munge"
   ```

8. On your source instance that you will use to burst nodes, edit the PBS configuration file (`/etc/pbs.conf`) and add this line:

   ```
   PBS_AUTH_METHOD=MUNGE
   ```

9. Restart the PBS MoM:

   ```
   systemctl restart pbs
   ```

For information about configuring encryption for PBS Professional, see "Authentication for Daemons & Users" on page 508 in the PBS Professional Administrator's Guide.

5.7.7.2 Add Encryption via TLS

Configure your instance to use TLS to encrypt communication.

To configure encryption on the instance that you will use as your image source, use TLS:

1. Log in as root
2. Edit PBS configuration file `pbs.conf`, and set the PBS_ENCRYPT_METHOD parameter:

   ```
   PBS_ENCRYPT_METHOD=tls
   ```

3. Make it so we can use the value of PBS_HOME in `pbs.conf`:

   ```
   # source /etc/pbs.conf
   ```

4. Create certificate directory `PBS_HOME/certs`:

   ```
   # mkdir ${PBS_HOME}/certs
   ```

5. Copy files from the PBS server host certificate directory into the VM certificate directory:
   a. Copy your `cert.pem` file to `${PBS_HOME}/certs/cert.pem`:

      ```
      # scp $PBS_SERVER:${PBS_HOME}/certs/cert.pem ${PBS_HOME}/certs/cert.pem
      ```

   b. Copy your `key.pem` file to `${PBS_HOME}/certs/key.pem`:

      ```
      # scp $PBS_SERVER:${PBS_HOME}/certs/key.pem ${PBS_HOME}/certs/key.pem
      ```

6. Set permissions and ownership for certificate directory:
   a. Make sure that permissions for the certificate directory and its contents are *0600:*

      ```
      # chmod -R 0600 ${PBS_HOME}/certs
      ```

   b. Make sure the owner is root on Linux or Administrator on Windows:

      ```
      # chown -R root: ${PBS_HOME}/certs
      ```

7. Restart PBS MoM:
   - On every Linux host in the complex:

     ```
     # <path to start/stop script>/pbs restart
     ```

     or

     ```
     # systemctl start pbs
     ```

   - On every Windows execution host in the complex:

     ```
     net stop pbs_mom
     net start pbs_mom
     ```

For information about configuring encryption for PBS Professional, see "Encrypting PBS Communication" on page 517 in the PBS Professional Administrator's Guide.

5.7.8 Create an OS Image

OTC documentation can be found at Creating a Linux Private Image.

1. Log in to the OTC Console.
2. Click Service List in the menu bar.
3. Under Computing, click Image Management Service.
4. Click + Create System Disk Image.
   a. For Region, select the same region that was chosen for the previously created VPC and ECS.
   b. For Source, click Server.
   c. For Server Type, click ECS.
   d. For ECS, select the virtual machine created for cloud bursting.
   e. If the virtual machine is not stopped, stop it.
   f. Click OK when prompted to verify that certain operations have been performed on the ECS. You do not need to configure or optimize the ECS.
   g. For Name, enter a name for the virtual machine.
5. Click Create Now.
6. Review the specifications.
7. Click Submit.
8. Click Back to Image List.

   The time required for creating an image varies depending on the image file size. Generally, it takes about 20 minutes to create an image. The image is successfully created when its image status changes to Normal.

   Do not perform any operation on the selected ECS or its associated resources during image creation.
9. You can delete the virtual machine now to avoid storage costs, or keep the virtual machine and update it over time to create updated OS images for bursting. You will incur storage costs, but this is an effective way to keep your OS images up to date when there are changes in packages, patches, or applications.

5.7.9 Create an OTC Cloud Bursting Scenario

5.7.9.1 Scenario Parameters to Collect at Vendor Interface

Make sure that you capture the following scenario parameters. We will remind you about them:

Table 5-12: Scenario Parameters for OTC

Scenario Parameter	What to Collect During Configuration at Vendor	Format
Cloud account	Name of your account at cloud vendor	String
Region	Region selected during configuration at cloud vendor	Drop-down list
Domain name	Domain used by cloud nodes	String
Hostname prefix	Optional prefix for burst node names; default is "node"; chosen during configuration at vendor	String

Table 5-12: Scenario Parameters for OTC

Scenario Parameter	What to Collect During Configuration at Vendor	Format
Subnet ID	ID of subnet for VPC created at cloud vendor	String
Security Group ID	ID of security group created at cloud vendor	String
OS Image URI	ID of OS image created at cloud vendor	String

5.7.9.2 Steps to Collect Information

1. Open a browser window and log in to the OTC Console.
2. Click Service List in the menu bar.
3. Under Network, click Virtual Private Cloud.
4. Click Virtual Private Cloud from the menu located on the left-hand side of the web page.
5. Click the name of the VPC you created for cloud bursting.
6. Click the name of the VPC's subnet.
7. Copy the Subnet ID.
8. **Save the subnet ID to a file**. You will need this later when you create a bursting scenario.
9. Click Security Group from the menu located on the left- hand side of the web page.
10. Click the name of the security group you created for the VPC.
11. Copy the ID of the security group.
12. **Save the security group to a file**. You will need this later when you create a bursting scenario.
13. Click Service List in the menu bar.
14. Under Computing, click Image Management Service.
15. Click the Private Images tab.
16. Click the name of the VM image you created for cloud bursting.
17. Copy the Image ID of the image.
18. **Save the OS Image ID to a file**. You will need this later when you create a bursting scenario.

5.8 Configuring OpenStack Cloud Bursting

You can find OpenStack documentation for the Stein release at https://docs.openstack.org/stein/index.html. For specific details, contact Altair support.

5.8.1 Get OpenStack Administrator Credentials

Get administrator credentials. While you work through the process of getting the administrator credentials, collect the following, and save them to a file:

Table 5-13: Account Parameters for OpenStack

Account Parameter	What to Collect During Configuration in Cloud Interface	Format
Auth URL	OpenStack: contact Altair support	String
User Domain Name	Domain name used to log in to your private cloud; see your OpenStack administrator	String
Username	Administrator username created using cloud interface	String
Password	Administrator password created using cloud interface	String

1. Find the username of the administrative user.
2. If you do not know the password, reset it.
3. **Save the password**. You will need this later when you add the administrative user account to PBS Cloud.

5.8.2 Create Virtual Private Cloud and OS Image

In the following sections, we touch on the steps to create a VPC and an OS image. While you are in the process, collect the following information, and save it to a file:

Table 5-14: Scenario Parameters for OpenStack

Scenario Parameter	What to Collect During Configuration at Vendor	Format
Cloud account	Name of your account at cloud vendor	String
Region	Region selected during configuration at cloud vendor	Drop-down list
Domain name	Domain used by cloud nodes	String
Hostname prefix	Optional prefix for burst node names; default is "node"; chosen during configuration at vendor	String
Subnet ID	ID of subnet for VPC created at cloud vendor	String
Security Group ID	ID of security group created at cloud vendor	String
OS Image URI	ID of OS image created at cloud vendor	String

5.8.2.1 Create a Virtual Private Cloud

Create a virtual private cloud using the Stein release of OpenStack:

1. Choose a region, a name, and an address range for the VPC.
2. Create a subnet and choose a name and an address range for it.
3. Create a security group and choose a name for it.

4. Add an inbound rule:
   - Use TCP
   - Use port 22
   - Choose IP Address
   - Specify your PBS Cloud firewall IP address

     Warning: 0.0.0.0/0 enables all IPv4 addresses to access your instance. ::/0 enables all IPv6 addresses to access your instance. This is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instance.

5.8.2.2 Create a Virtual Machine

Create a virtual machine using the instructions for your cloud. We recommend the following:

- Create a key pair, give it a name, and save the .pem file containing the key pair to your local disk in a secure location. PBS Cloud will use this later to manage cloud nodes.
- Choose the same region you chose for the VPC.
- Choose an availability zone, if you have more than one
- Choose a type that fits your needs.
- Use a public image.
- Choose a supported OS
- Choose the disk characteristics you need.
- Assign the VPC you created.
- Assign the security group you created.
- Choose the Key Pair login mode.
- For the key pair, choose the .pem file you generated.
- Give the VM a name.
- Select a quantity of 1 for the number of nodes.

  It may take some time to create the virtual machine.

5. You can delete the virtual machine now to avoid storage costs, or keep the virtual machine and update it over time to create updated OS images for bursting. You will incur storage costs, but this is an effective way to keep your OS images up to date when there are changes in packages, patches, or applications.

5.8.2.3 Install and Configure a PBS MoM on the Virtual Machine

1. Get the public IP address of the VM.
2. Log in to your site's PBS server host.
3. SSH into the VM using the default user "root", the .pem file you generated when creating the VM and the external IP address assigned to the VM.

   ```
   ssh -i /<path to .pem>/<.pem filename>.pem root@<public IP of VM>
   ```

4. Using the PBS Professional Installation and Upgrade Guide, install and configure the PBS MoM.

5. Configure the VM to work with your site environment, for example mounting file systems, connecting to the authentication service, installing any applications you need, etc. We recommend that you include the following:
   - Mount /home in the VM
   - Either install applications in the VM or cross-mount them from the PBS server host
   - Either add users to the password file or connect the VM to a service such as NIS
6. If `cloud-init` is not installed, install it.

5.8.2.4 Add Authentication and Encryption

5.8.2.4.i Add Authentication via MUNGE

Configure your instance to use MUNGE to authenticate users and daemons.

To configure authentication on the instance that you will use as your image source, use MUNGE:

1. Log in as root
2. Download and install a supported version of MUNGE. You can get MUNGE either via your Linux distribution package repositories or from the MUNGE project directly.

   Follow the MUNGE installation instructions at https://github.com/dun/munge/wiki/Installation-Guide.
3. On the PBS server host, generate the munge.key file using the `create-munge-key` command.
4. On every host, if the library name is not exactly "libmunge.so", for example "libmunge.so.2", add a soft link to it. For example:

   ```
   ln -s /lib64/libmunge.so.2 /lib64/libmunge.so
   ```
5. Copy /etc/munge/munge.key from the PBS server host to the source instance:

   ```
   # scp $PBS_SERVER:/etc/munge/munge.key /etc/munge/munge.key
   ```
6. Start MUNGE:

   ```
   systemctl start munge
   ```
7. Make sure that on the PB server host, the PBS configuration file (`/etc/pbs.conf`) contains these lines:

   ```
   PBS_AUTH_METHOD=MUNGE
   PBS_SUPPORTED_AUTH_METHODS="pwd,munge"
   ```
8. On your source instance that you will use to burst nodes, edit the PBS configuration file (`/etc/pbs.conf`) and add this line:

   ```
   PBS_AUTH_METHOD=MUNGE
   ```
9. Restart the PBS MoM:

   ```
   systemctl restart pbs
   ```

For information about configuring encryption for PBS Professional, see "Authentication for Daemons & Users" on page 508 in the PBS Professional Administrator's Guide.

5.8.2.4.ii Add Encryption via TLS

Configure your instance to use TLS to encrypt communication.

To configure encryption on the instance that you will use as your image source, use TLS:

1. Log in as root
2. Edit PBS configuration file pbs.conf, and set the PBS_ENCRYPT_METHOD parameter:

   PBS_ENCRYPT_METHOD=tls
3. Make it so we can use the value of PBS_HOME in pbs.conf:

   # source /etc/pbs.conf
4. Create certificate directory PBS_HOME/certs:

   # mkdir ${PBS_HOME}/certs
5. Copy files from the PBS server host certificate directory into the VM certificate directory:
   a. Copy your cert.pem file to ${PBS_HOME}/certs/cert.pem:

      # scp $PBS_SERVER:${PBS_HOME}/certs/cert.pem ${PBS_HOME}/certs/cert.pem

   b. Copy your key.pem file to ${PBS_HOME}/certs/key.pem:

      # scp $PBS_SERVER:${PBS_HOME}/certs/key.pem ${PBS_HOME}/certs/key.pem
6. Set permissions and ownership for certificate directory:
   a. Make sure that permissions for the certificate directory and its contents are *0600:*

      # chmod -R 0600 ${PBS_HOME}/certs

   b. Make sure the owner is root on Linux or Administrator on Windows:

      # chown -R root: ${PBS_HOME}/certs
7. Restart PBS MoM:
   - On every Linux host in the complex:

     # <path to start/stop script>/pbs restart

     or

     # systemctl start pbs
   - On every Windows execution host in the complex:

     net stop pbs_mom

     net start pbs_mom

For information about configuring encryption for PBS Professional, see "Encrypting PBS Communication" on page 517 in the PBS Professional Administrator's Guide.

5.8.2.5 Create OS Image from VM

Follow your cloud instructions to create an OS image from the VM you created. Use the same region you chose for the VPC.

On Azure, you can now delete the virtual machine so that you are no longer charged for it.

On AWS, you can delete the virtual machine now to avoid storage costs, or keep the virtual machine and update it over time to create updated OS images for bursting. You will incur storage costs, but this is an effective way to keep your OS images up to date when there are changes in packages, patches, or applications.

5.9 Configuring Alibaba Cloud Bursting

5.9.1 Create Alibaba Cloud Account

You create a user account at the cloud provider; the user account you create will have administrative rights to any machines hosted in the cloud. This account is used to create cloud environment elements such as VPCs, instances, and networks.

When you ssh into cloud nodes and do operations inside cloud nodes, you operate as root.

Here is an outline of the steps to create your Alibaba cloud account:

1. Sign up for an Alibaba cloud account
2. Create an Alibaba Cloud Resource Access Management (RAM) user account
3. Grant permissions to the Cloud RAM user

Save the account information for later. **Save** the account name, and during the process of creating your Alibaba cloud account, make sure you download a CSV file containing the following:

- Access Key ID
- Access Secret Key

We will remind you of this step.

5.9.1.1 Steps for Creating Alibaba Cloud Account

1. Go to the login page of the International site (alibabacloud.com)
2. Click *Sign In as RAM User*
3. Log in to the RAM console by using your Alibaba Cloud account.
4. In the navigation pane on the left-hand side of the web page, choose *Identities -> Users*
5. Click *Create User*
6. Enter the following information:
   a. For Logon Name, enter a name for the user
   b. For Display Name, enter a name that will be displayed for the user. The name can be anything meaningful to your organization, e.g. "ali_cloud_user".
   c. For Access type, enable OpenAPI access; this allows PBS to make API calls or use the Alibaba Cloud CLI
7. Click *OK* to generate an AccessKey pair consisting of an Access Key ID and an Access Secret Key for the user
8. Click *Download CSV File* to download the AccessKey pair information
9. **Save** the CSV file in a secure location

   PBS Cloud will use the access key ID and secret access key in this file to manage cloud nodes
10. Grant administrator permissions to the user by choosing *Identities > User*
11. In the Actions column, click *Add Permission* for the user.
12. Select the AdministratorAccess system policy; use the default settings for all parameters.
13. Click *OK* to attach the system policy to the administrator. This attaches a policy of roles and permissions to the user you have created.

5.9.2 Create a Virtual Private Cloud and a vSwitch (Subnet)

1. Log in to the Alibaba Cloud Management Console
2. Choose a region based on the geographical location of your users. All cloud resources that are created are placed in this region.

   Availability of instance types is determined by the region that you select and the resource inventory in the region. You can go to the *ECS Instance Types Available for Each Region* page to view the instance types available in each region.
3. **Save** the region for later when you tell PBS Cloud about it.
4. Move the cursor over the menu button in the upper left corner. The Products and Services page is displayed.
5. In the Products and Services menu, use the search box to search for "vpc"
6. Choose the "virtual private cloud" option to open the VPC console
7. In the top navigation bar, select the region where you want to create a VPC and a vSwitch
8. Create a Resource Group. This is a convenience for filtering and tracking resources.
   a. Go to the All Resources dropdown at the top of the page and click Manage Resource Groups. This takes you to a separate page.
   b. On this separate page, create a resource group:
      1. Click *Create Resource Group*
      2. Provide a Resource Group Identifier and Display Name (they can be the same)
9. Navigate back to the VPC page
10. Click *All Resources* at the top of the VPC page and select your resource group
11. On the VPCs page, click *Create VPC*
12. Enter the following to create a VPC:
    a. For Region, make sure the region you selected in the top navigation bar is displayed
    b. For Name, enter any name for the VPC. The name can be anything meaningful to your organization, e.g., bursting_vpc.
    c. For IPv4 CIDR block, provide an address range in CIDR notation, e.g. "10.17.0.0/24"
    d. For Description, enter a meaningful description for the VPC
    e. For Resource Group, select the resource group to which the VPC belongs
    f. For vSwitch Name, enter a name for the vSwitch (2 to 128 characters long, begins with an alphabetic, can contain digits, underscores, and hyphens)
    g. For Zone, select a zone for the vSwitch from the drop-down menu. Each vSwitch works in one zone. The page offers you vSwitches in your region. You need a vSwitch in each zone where you burst nodes. A vSwitch in one zone can communicate with vSwitches in other zones in the same region. Allowing a vSwitch to communicate with a vSwitch in a different region requires more setup and costs extra.
    h. Take note of the zone you selected and **save** it. You will need this later.
    i. For IPv4 CIDR, enter an IPv4 CIDR block for the vSwitch; this must be a subset of the CIDR for the VPC.

       You can add at most 10 vSwitches in each VPC.

       You cannot change the CIDR block of a vSwitch after it is created.
13. Click *OK*.

5.9.3 Create a Virtual Machine

Here are the steps to create a virtual machine in Alibaba Cloud Elastic Compute Service (ECS) console:

1. Log in to the Alibaba cloud console
2. Move the cursor over the menu button in the upper left corner. The Products and Services page is displayed.
3. In the Products and Services menu, use the search box to search for "Elastic Compute Service"
4. Search for "Elastic Compute Service" and click the search result link to open the ECS console
5. Click *Instances* from the menu located on the left-hand side of the web page
6. Click *Create Instance*.
7. Click the *Custom Launch* tab.
8. In the Basic Configurations section, fill in the following:
   a. For Billing Method, choose the subscription type suitable for your instance. We suggest using "Pay-as-you-go" because you only need this instance for the process of creating your VM, but you want to make sure the instance is not preempted while you are using it.
   b. For Region, select the region you want the instance to be in
   c. For Zone, select one of the zones you chose for a vSwitch.

      You cannot change the region or zone after the instance is created.
   d. For Instance Type, choose *Type-based Selection*, *x86-Architecture*, and the *General Purpose* category. (This is the only supported combination)
   e. Choose a specific instance type based on your requirements for vCPU, Memory, Clock Speed, Network Bandwidth and pricing
   f. For Image, select *Public Image*.
      1. Go to the Alibaba Cloud Linux drop-down menu. Choose the Linux flavor you want.
      2. Go to the Select a Version drop-down and choose the version you want.

      This is your base image.
   g. For Storage, select *System Disk*
   h. For Disk specifications and performance choose *Enhanced SSD (ESSD)*. Enhanced SSD is required.

      40GB is the minimum recommended amount.
9. Click *Next*
10. In the Networking section, fill in the following:
    a. For Network Type, select the VPC and vSwitch you created
    b. For Public IP Address, select *Assign Public IPv4 Address*
    c. For Bandwidth Billing, select *Pay-By-Traffic*
    d. For Peak Bandwidth, set a speed of 4 Mbps
    e. For Security Group, you can either accept the default or you can create what you want:
       1. Click on *Create Security Group*. This brings up a form.
       2. The form pre-selects your VPC
       3. Select your resource group
       4. Set the rules you want for inbound and outbound access.

By default, security groups block all incoming connections and allow all outbound connections.

To be able to connect via the Internet, allow access to port 22 from 0.0.0.0/0 and/or from the IP address from which you will connect to the cloud nodes (this happens in the default security group).

You can update the security group later if you need to add connections.

5. Click *Create Security Group* at the bottom of the form

11. Navigate back to the Networking section
12. Select the security group you just created or accepted by clicking the *Reselect Security Group* button
13. Click *Next*
14. In the System configurations section:
    a. For Logon Credentials, choose "Key Pair"
    Note that the preselected username is "root".
    b. Click *Create Key Pair*
    c. Generate an SSH key pair by autocreating or importing it
    d. Provide an instance name (this is a friendly name for your own purposes) and a description
15. In the Grouping (optional) section:
    a. For Tags, select the tags for the instance
16. Click *Next*
17. In the Preview step, confirm the configurations in the Configurations Selected section or click the *Edit* icon to modify configurations.
18. Read and select *ECS Terms of Service*.
19. Click *Create Instance*
20. In the Created message box, click *Console* to view the instance creation progress on the Instances page. If the instance is created, it is in the *Running* state
21. Copy the public IP address of the instance so that you can use it when you want to connect to the ECS instance.

5.9.4 Install a PBS MoM on the VM

The user who logs into the virtual machine is root; root uses the SSH key that you specified during creation of the VM.

You may want to use a `cloud-init` script. The script configures cloud nodes so that they meet your needs. See Chapter 6, "The Cloud Node Startup Script", on page 155.

1. Log in to the VM as root
2. ssh into the virtual machine using the public IP address of the VM:

```
ssh <public IP address of VM>
```

3. Copy the appropriate PBS Professional installation package to the VM.
4. Using the *PBS Professional Installation and Upgrade Guide* and the *PBS Professional Administrator's Guide*, install and configure the PBS Professional MoM
5. Configure the VM for your site's environment. For example, mount file systems, connect it to the authentication service, install any applications, etc.
6. If `cloud-init` is not installed, install it. To see whether it is installed:

```
yum list installed | grep cloud
```

7. Test the VM:

   a. Tell the PBS Professional server about the VM so that we can test whether we can submit a job to it:

   ```
   qmgr -c 'create node <IP address of VM>'
   ```

   a. Create a queue for this node only:

   ```
   qmgr -c 'create queue cloudtestqueue'
   qmgr -c 'set queue cloudtestqueue queue_type=execution'
   qmgr -c 'set queue cloudtestqueue enabled=true'
   qmgr -c 'set queue cloudtestqueue started=true'
   ```

   a. Attach the node to the queue via a custom resource; see "Associating Vnodes with Queues" on page 106 in the PBS Professional Administrator's Guide.

   a. Submit a job to ensure it is working as expected:

   ```
   qsub -q cloudtestqueue -- /bin/sleep 60
   ```

5.9.5 Create a Custom OS Image

You can find Alibaba Cloud documentation at *Create a custom image from an instance*.

1. Log in to the Alibaba cloud console
2. Move the cursor over the menu button in the upper-left corner. The Products and Services page is displayed.
3. In the Products and Services page, search for Elastic Compute Service and click the search result link to open the ECS console
4. Click *Instances* from the menu located on the left-hand side of the web page
5. Click *More* in the Actions column of the instance from which an image has to be created
6. Select *Disk and Image -> Create Custom Image*
7. In the Create Custom Image page:
   a. For Custom Image Name, provide a suitable name
   b. For Custom Image Description, provide a brief description of the image
   c. You can add Image Family, Resource Groups, and tags as per your requirements
8. Click *Create*

   Save the name and ID of the custom image you created. You will use the image ID and name of the custom image in PBS Cloud to create a cloud bursting scenario.

5.9.6 Collect Information for an Alibaba Cloud Bursting Scenario

5.9.6.1 Scenario Parameters to Collect at Vendor Interface

Make sure that you capture the following scenario parameters:

Table 5-15: Scenario Parameters for Alibaba Cloud

Scenario Parameter	What to Collect During Configuration at Vendor	Format
Cloud account	Name of your account at cloud vendor	String
Region	Region selected during configuration at cloud vendor. Use the exact string listed in the Regions and Zones list	String
Domain name	Domain used by cloud nodes	String
Hostname prefix	Optional prefix for burst node names; default is "node"; chosen during configuration at vendor	String
Zone	Zone selected during VPC creation. Use the exact string listed in the Regions and Zones list	String
VPC ID	ID of VPC you created	String
vSwitch ID	ID of vSwitch you created	String
Image ID	ID of custom image you created at cloud vendor	String
Security Group ID	Security group ID associated with VPC and VM you created at vendor	String

5.9.6.2 Steps to Collect Information

1. Collect the name of the custom image you created in Section 5.9.5, "Create a Custom OS Image"
1. Open a browser window and log in to the Alibaba cloud console
2. Move the cursor over the menu button in the upper left corner. The Products and Services page is displayed.
3. Collect VPC ID:
   a. Search for VPC and click the search result link to open the VPC console
   b. Copy the ID of the VPC to be used for the cloud bursting scenario
4. Collect vSwitch ID:
   a. Click vSwitch from the VPC menu located on the left-hand side of the web page
   b. On the vSwitch page, find the vSwitch that you want to use and copy its ID
5. Collect security group:
   a. In the left-side navigation pane, choose *Network & Security > Security Groups*
   b. Find the security group that you want to use and copy its ID

5.9.7 Alibaba Cloud Regions and Zones

Alibaba Cloud segregates geography by regions, and segregates region by zones. Information related to the regions is available in the Alibaba cloud documentation.

5.9.7.1 Zone IDs for Specific Regions

Here is a list of regions and their zone IDs:

"cn-qingdao"

- "cn-qingdao-c"
- "cn-qingdao-b"

"cn-beijing"

- "cn-beijing-k"
- "cn-beijing-h"
- "cn-beijing-g"
- "cn-beijing-f"
- "cn-beijing-e"
- "cn-beijing-d"
- "cn-beijing-c"
- "cn-beijing-b"
- "cn-beijing-a"
- "cn-beijing-i"
- "cn-beijing-j"
- "cn-beijing-l"

"cn-zhangjiakou"

- "cn-zhangjiakou-a"
- "cn-zhangjiakou-c"
- "cn-zhangjiakou-b"

"cn-huhehaote"

- "cn-huhehaote-a"
- "cn-huhehaote-b"

"cn-wulanchabu"

- "cn-wulanchabu-b"
- "cn-wulanchabu-a"
- "cn-wulanchabu-c"

"cn-hangzhou"

- "cn-hangzhou-k"
- "cn-hangzhou-i"
- "cn-hangzhou-j"
- "cn-hangzhou-h"
- "cn-hangzhou-g"
- "cn-hangzhou-f"
- "cn-hangzhou-b"
- "cn-hangzhou-e"
- "cn-hangzhou-d"
- "cn-hangzhou-c"

"cn-shanghai"

- "cn-shanghai-l"
- "cn-shanghai-b"
- "cn-shanghai-g"
- "cn-shanghai-f"
- "cn-shanghai-e"
- "cn-shanghai-d","cn-shanghai-c"
- "cn-shanghai-a"
- "cn-shanghai-k"
- "cn-shanghai-m"
- "cn-shanghai-n"

"cn-shenzhen"

- "cn-shenzhen-e"
- "cn-shenzhen-f"
- "cn-shenzhen-d"
- "cn-shenzhen-c"
- "cn-shenzhen-a",
- "cn-shenzhen-b"

"cn-heyuan"

- "cn-heyuan-b"
- "cn-heyuan-a"

"cn-guangzhou"

- "cn-guangzhou-a"
- "cn-guangzhou-b"

"cn-chengdu"

- "cn-chengdu-a"
- "cn-chengdu-b"

"cn-hongkong"
- "cn-hongkong-b"
- "cn-hongkong-c"
- "cn-hongkong-d"

"ap-northeast-1"
- "ap-northeast-1b"
- "ap-northeast-1a"

"ap-northeast-2"
- "ap-northeast-2a"

"ap-southeast-1"
- "ap-southeast-1c"
- "ap-southeast-1b"
- "ap-southeast-1a"

"ap-southeast-2"
- "ap-southeast-2b"
- "ap-southeast-2a"

"ap-southeast-3"
- "ap-southeast-3a"
- "ap-southeast-3b"

"ap-southeast-6"
- "ap-southeast-6a"

"ap-southeast-5"
- "ap-southeast-5a"
- "ap-southeast-5b"
- "ap-southeast-5c"

"ap-south-1"
- "ap-south-1b"
- "ap-south-1a"

"ap-southeast-7"
- "ap-southeast-7a"

"us-east-1"
- "us-east-1b"
- "us-east-1a"

"us-west-1"
- "us-west-1b"
- "us-west-1a"

"eu-west-1"
- "eu-west-1b"
- "eu-west-1a"

"me-east-1"

- "me-east-1a"

"eu-central-1"

- "eu-central-1b"
- "eu-central-1a"

"cn-nanjing"

- "cn-nanjing-a"

5.10 Windows Bursting on AWS and Azure

Bursting of Windows virtual machines is supported on AWS and Azure. Windows cloud bursting is similar to cloud bursting on Linux platforms. Three special requirements are necessary to burst Windows cloud nodes.

5.10.1 OS Image Name

When creating the OS image, the name of the image must contain the term "windows" (case insensitive). For example, on AWS, the AMI Name should look something like this:

```
Windows_Server-2012-R2_RTM-English-64Bit- Base-2019.11.13
```

On Azure, the Image Name should look something like Windows Server 2012 R2 Datacenter.

5.10.2 Inbound Security Rule for RDP

Secondly, an inbound rule to open the port 3389 must be added to the AWS security group or the Azure network security group that is associated with the cloud provider virtual network. This allows a connection to be made to the Windows VM via RDP so that the PBS MoM can be installed.

For more information see AWS: Authorizing Inbound Traffic for Your Windows Instances and Azure: Cannot connect remotely to a VM because RDP port is not enabled in NSG.

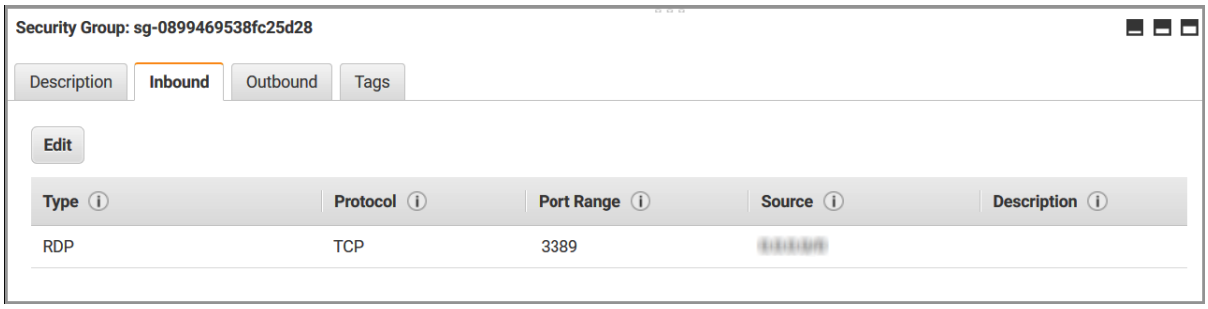

Figure 5-33:AWS Inbound Security Rule for RDP

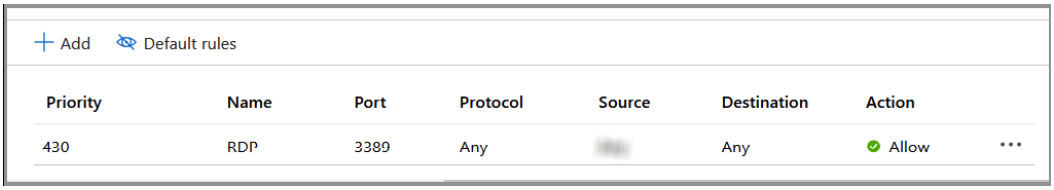

Figure 5-34:Azure Inbound Security Rule for RDP

5.10.3 Startup Script

The cloud node startup script must use a PowerShell script. For more information see PowerShell Scripting. The below PowerShell script example generates a file in C:\Windows\Temp:

```
<powershell>
$file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
```

5.10.4 See Also

- "Configuring Amazon Web Service Cloud Bursting" on page 69
- "Configuring Microsoft Azure Cloud Bursting" on page 82

6 The Cloud Node Startup Script

6.1 Introduction

For each scenario, you will want to do some configuration of each cloud node after it boots. The simplest way to configure an instance at boot time is to use a shell script. You can add a startup script to each bursting scenario that runs when a scenario instance boots, in order to perform automated tasks to customize your cloud nodes. For example, you may want to install packages, perform updates, start services, add users, configure filesystems (`/etc/fstab`), configure NIS (`/etc/yp.conf`), or mount necessary filesystems.

The `cloud-init` tool is a utility for initializing cloud instances. PBS Cloud uses the `cloud-init` tool to launch its own startup script first to configure each freshly burst cloud node so that the PBS server can connect to the cloud node. If you use a startup script, it runs after the built-in script.

For more information on `cloud-init`, see the `cloud-init` documentation at cloud-init.

Note that you may not need a startup script. If you configure the VM that you use to create your OS image to have everything you need to run jobs, you do not need a startup script.

6.1.1 Making cloud-init Tool Available in OS Image

For each scenario, you create an OS image that includes the `cloud-init` tool. Make sure that `cloud-init` is installed in the VM that you use to create the image (we include that step in the instructions). Sometimes it is pre-installed; if it's not there, install it. For example, on CentOS:

```
yum install -y cloud-init
```

6.1.2 Adding a cloud-init Script to a Scenario

You add a `cloud-init` script to each scenario via the PBS Cloud web interface; see section 3.3.4.3, “Specifying the Cloud Node Startup Script”, on page 40. You can add a script while creating a scenario, and you can edit the script or choose a new script later. The startup script to be included in a scenario can be located anywhere that your PBS Cloud web interface can browse to. Once a script has been added to a scenario, the script is stored in the PBS Cloud database.

Make sure you develop the startup script for each scenario. See section 6.3, “Developing the Startup Script”, on page 159.

6.1.3 Startup Script Prerequisites

- The startup script must run using a shell or language available in the freshly burst node. For example, if you have `bash` and Python available, your script can use `bash`, or it could use a `bash` script to launch a Python script.
- On Windows cloud nodes, use a PowerShell startup script. Enclose the content of the PowerShell script in <powershell> and </powershell>. Refer to Microsoft documentation for more information about PowerShell.
- The startup script can have any name.

6.1.4 Startup Script Recommendations

- We strongly recommend mounting /home to simplify making each cloud node usable for jobs.
- We recommend installing your applications somewhere and then mounting that directory in each cloud node.

6.2 Customizing Your Startup Script

Make sure that your startup script uses the correct locations for PBS_HOME, PBS_EXEC, etc.

6.2.1 Mounting /home Directory

We strongly recommend that you mount /home so that users can run jobs in the cloud node. This makes user SSH keys available, and /home can be used for PBS data transfer. If you do not mount /home, you have to create a /home directory in the image, pre-fill it for each user who will submit jobs, and set up the user space.

```
echo "<PBS server host IP address> <PBS server hostname> <PBS server hostname>.<domain name>" >>
    /etc/hosts
...
...
yum install -y nfs-utils
mount -t nfs <hostname of machine with /home>:/home /home
```

6.2.2 Configuring MoM for Local Copy

We recommend that you set the $usecp MoM configuration parameter to tell the MoM which local directories are mapped to mounted directories, so that MoM can use the local copy mechanism for them:

```
echo "<PBS server host IP address> <PBS server hostname> <PBS server hostname>.<domain name>" >>
    /etc/hosts
...
...
echo "\$usecp <hostname of machine with /home>:/home/ /home/" >> /var/spool/pbs/mom_priv/config
```

See "Letting MoM Know Whether Transfer is Local or Remote" on page 441 in the PBS Professional Administrator's Guide.

6.2.3 Creating Local Scratch Space

You can create local scratch on a fast local disk and use it as the default location where PBS runs jobs, if PBS will be creating the directories where jobs run. To do this, each job must have its sandbox attribute set to *PRIVATE*, and the $jobdir_root MoM configuration parameter has to be set to /scratch.

```
mkdir /scratch
chmod 1777 /scratch
```

For example, if /scratch is not shared:

```
echo "\$jobdir_root /scratch" >> /var/spool/pbs/mom_priv/config
```

6.2.3.1 Creating Job-specific Staging and Execution Directories

Whether or not PBS creates job-specific staging and execution directories for a job is controlled by the job's sandbox attribute:

- If the job's sandbox attribute is set to *PRIVATE*, PBS creates a staging and execution directory for each job, in the location specified by the $jobdir_root MoM parameter. If the $jobdir_root parameter is unset, PBS creates job-specific staging and execution directories in the job submitter's home directory.
- If the job's sandbox attribute is set to *HOME* or is unset, PBS does not create job-specific staging and execution directories. Instead PBS uses the job submitter's home directory.

6.2.3.2 Using Shared Directories for Staging and Execution

Using a shared directory for job staging and execution is a little more complicated when nodes are released early from a job. Normally each MoM on a sister node that is being released cleans up its own files upon release. However, if the directory is shared, you need to prevent those sister MoM(s) from prematurely cleaning up job files before the job has finished. This is an issue whether or not the directory is the user home directory. You take care of this by specifying whether the directory is shared via the $jobdir_root MoM parameter:

- When staging and execution directories are to be created in a shared (e.g. NFS) directory specified in `$jobdir_root`, set the *shared* directive after the directory name:

  $jobdir_root <directory name> shared

  For example:

  ```
  echo "\$jobdir_root /scratch shared " >> /var/spool/pbs/mom_priv/config
  ```

- If job submitter home directories are shared, tell MoM:

  $jobdir_root PBS_USER_HOME shared

  For example:

  ```
  echo "\$jobdir_root PBS_USER_HOME shared " >> /var/spool/pbs/mom_priv/config
  ```

See "Staging and Execution Directories for Job" on page 473 in the PBS Professional Administrator's Guide.

6.2.4 Example cloud-init Startup Script for Linux

Example 6-1: `cloud-init` startup script for Linux. Do not use this script as is; make sure you adapt it for your site.

```
#!/bin/sh
# Map PBS server host IP address to hostnames via /etc/hosts
echo "/etc/hosts setup"
rm -f /etc/hosts
echo "127.0.0.1 localhost localhost.localdomain localhost4 localhost4.localdomain4" > /etc/hosts
echo "<PBS server host IP address> <PBS server host> <PBS server host>.<cloud node domain>" >>
    /etc/hosts

# Disable NetworkManager and use network interface
# so that it does not overwrite the /etc/resolv.conf file
systemctl disable NetworkManager
systemctl stop NetworkManager
systemctl enable network
systemctl start network

# Configure PBS via /etc/pbs.conf
echo "PBS setup"
systemctl stop pbs
rm -f /etc/pbs.conf
echo "PBS_EXEC=/opt/pbs/default" > /etc/pbs.conf
echo "PBS_HOME=/var/spool/PBS" >> /etc/pbs.conf
echo "PBS_START_SERVER=0" >> /etc/pbs.conf
echo "PBS_START_MOM=1" >> /etc/pbs.conf
echo "PBS_START_SCHED=0" >> /etc/pbs.conf
echo "PBS_START_COMM=0" >> /etc/pbs.conf
echo "PBS_SERVER=PBS_SERVER_HOSTNAME" >> /etc/pbs.conf
echo "PBS_CORE_LIMIT=unlimited" >> /etc/pbs.conf
echo "PBS_SCP=/bin/scp" >> /etc/pbs.conf

# Update pbs.conf with the cloud node's IP address
IP=$(ip addr show eth0 | grep "inet\b" | awk '{print $2}' | cut -d/ -f1)
echo "PBS_MOM_NODE_NAME=$IP" >> /etc/pbs.conf

# Configure the MoM by updating PBS_HOME/mom_priv/config
echo "MoM configuration setup"
. /etc/pbs.conf
echo "\$clienthost $PBS_SERVER" >> /var/spool/pbs/mom_priv/config
echo "\$clienthost ${PBS_SERVER//.*}" >> /var/spool/pbs/mom_priv/config
echo "\$restrict_user_maxsysid 999" >> /var/spool/pbs/mom_priv/config

# Restart PBS
systemctl start pbs
```

6.3 Developing the Startup Script

Troubleshooting issues with cloud bursting can be difficult and time consuming. Issues that can arise include the following:

- Network issues
- SSH key issues
- Missing users or groups
- Missing packages
- Mounted file system errors

6.3.1 Prerequisites for Developing a Startup Script

- You have installed PBS Professional, Simulate, and PBS Cloud, configured PBS Professional and Simulate, created a cloud administrator account at your cloud provider and added that account to PBS Cloud, created and configured your cloud provider components including an OS image, and configured the PBS Cloud module. These steps are outlined in section 3.1, “Overview of Configuring PBS Cloud”, on page 21.
- Make sure the cloud bursting hooks are disabled.
- You should have at least one PBS Cloud scenario to test.
- This scenario must be enabled.
- The Add Public IP to VMs scenario option is enabled; see section 3.3.4.2, “Temporarily Adding Public IP for Debugging”, on page 40
- The SSH keys parameter has an administrator SSH key; see section 3.3.4.4, “Adding SSH Key for Access to Burst Nodes”, on page 41
- You have the corresponding private key
- Port 22 in the vendor firewall has to be open (already covered when you were configuring vendor components)

6.3.2 What to Test For

- You can log into the node
- The `/home` directory is mounted
- The directory containing your applications is mounted
- Make sure applications work
- Make sure the node was added to PBS (use `pbsnodes -a`)
- All references work on the internal network; don't use external IP addresses
- You can `ping` and `ssh` from the cloud node to the PBS server host and vice versa
- The cloud infrastructure (VPN connectivity, networks, firewalls etc.) is working
- On the cloud node, the hostname for the PBS server appears in the following:
  `/etc/pbs.conf`
  `/etc/hosts`
  `/var/spool/pbs/mom_priv/config`

6.3.3 Steps to Develop the Startup Script

We recommend that you burst a single cloud node, test it, and resolve one issue at a time. Each time you resolve an issue, keep a log of your changes, and incorporate your solution into the `cloud-init` script. You can log your command-line input as you work to resolve the issue, and convert this record into script inputs.

Once the cloud node is configured correctly, you can enable the cloud bursting hooks, use the relevant hook to burst cloud nodes, and troubleshoot the cloud bursting hooks.

6.3.4 Example of Developing a cloud-init Script

This example is intended to be used after you have installed PBS Professional and PBS Cloud, configured PBS Professional, created a cloud administrator account at your cloud provider and added that account to PBS Cloud, created and configured your cloud provider components including an OS image, and configured the PBS Cloud module. These steps are outlined in section 3.1, "Overview of Configuring PBS Cloud", on page 21.

Make sure the cloud bursting hooks are disabled.

You should have at least one PBS Cloud scenario to test. This scenario must be enabled.

1. If you have not already prepared the scenario for developing a startup script:
   a. Create a `cloud-init` script by copying the example `cloud-init` script
   b. In the script, map the PBS server host to its IP address:

   ```
   echo "<PBS server host IP address> <PBS server hostname> <PBS server hostname>.<cloud node domain name>" >> /etc/hosts
   ```

   c. Make any other necessary changes to the script
   d. Upload the `cloud-init` script to the scenario. Enable the Add public IP to VMs option for the scenario, and add a suitable public SSH key to the scenario. Make sure you have the corresponding private key.
2. Log in to PBS Cloud.
3. Click the Cloud tab.
4. Under Infrastructure, click Bursting.
5. Select a bursting scenario by clicking on its name.
6. Go to the Node tab.
7. Under Machines (manually burst), click "Burst machines"
8. Choose the instance type and OS. Set the number of cloud nodes to be 1.
9. Choose "Burst", then confirm.
10. Once the cloud node is burst, attempt to SSH into the cloud node using the value of the private_ip parameter that is returned from the PBS Cloud CLI bursting command.
11. If you encounter a "Permission denied" error, there is a problem with the cloud node configuration and/or the `cloud-init` script. Each user's SSH keys are stored in the user's home directory under the .ssh directory and the public key has been added to `.ssh/authorized_keys` in the user's home directory, so SSH should be working. .
12. Using PuTTY or a similar SSH client, SSH into the cloud node using the cloud node's public IP address (the value of the parameter public_ip address returned from the PBS Cloud bursting command) and your previously generated private SSH key (matching the public key used in the bursting scenario).
13. Check the contents of the `/etc/hosts` file. If the PBS server hostname is mapped to its IP address, the `cloud-init` script is being run.

14. Check which filesystems have been mounted using the `df` command. If `/home` is not mounted, this is the cause of the SSH failure to the private IP address of the cloud node.
15. Use the `ls` command to see whether `/home` exists.
16. To mount the directory, install `nfs-utils` and then mount `/home`:

```
yum install nfs-utils
mount -t nfs <PBS server hostname>:/home /home
```

17. Log in to PBS Cloud.
18. Click the Cloud tab.
19. Under Infrastructure, click Bursting.
20. Select a bursting scenario by clicking on its name.
21. Under Machines (manually burst), click Manual unbursting page.
22. Enabling the check box to the right of the cloud node.
23. Click Unburst.
24. Click Unburst machines to confirm the action.
25. Edit the bursting scenario.
26. Edit the `cloud-init` script.
27. Copy the two commands to install `nfs-utils` and mount `/home` and paste them into the `cloud-init` script.
28. Save the `cloud-init` script.
29. Burst another cloud node and repeat the process.

6.3.5 Caveats for Testing Startup Script

Occasionally you will burst a node that appears to be correct in all respects, but it simply won't run a job. Sometimes you just get a bad node. In this case, unburst the node and burst a new one.

7 Managing Cloud Bursting

7.1 Logging into PBS Cloud

To log into PBS Cloud, go to the PBS Cloud interface in your web browser:

```
http://<PBS Cloud hostname or IP address>:<port>/pbspro-cloud/#/login
```

The default port is 9980.

7.2 Managing Cloud Bursting

7.2.1 Viewing Cloud Account Details

1. Log in to PBS Cloud.
2. Click the Cloud tab.
3. Under Infrastructure, click Cloud.
4. Select a cloud account by clicking on its name.

   The information that was entered to create the cloud account is displayed.
5. Click Close.

7.2.2 Manually Bursting Cloud Nodes

Here we describe how to use the PBS Cloud GUI to manually burst cloud nodes.

The steps for bursting bare metal instances are the same as for other instance types.

1. Log in to PBS Cloud.
2. Click the Cloud tab.
3. Under Infrastructure, click Bursting.
4. Select a bursting scenario by clicking on its name.
5. Go to the Node tab.
6. Under Machines (manually burst), click "Burst machines"
7. Choose the instance type and OS.
8. Choose the number of nodes to burst.
9. Choose "Burst", then confirm.

7.2.2.1 Tagging Burst Nodes

The PBS cloud bursting hooks always add a tag named "burst-by" and set its value to "pbs-cloudhook".

You can use the same tag with a different value, or a different tag altogether, to distinguish manually burst nodes from those burst via the cloud bursting hooks.

7.2.2.2 Caveats for Manually Burst Nodes

Cloud nodes that are manually burst remain up and running until explicitly unburst.

7.2.3 Viewing Burst Cloud Nodes

Information that is displayed about cloud nodes:

Machine Name
: Hostname of the node.

IP Address
: IP address assigned to the node.

Instance Type
: Cloud provider instance type (machine type, shape or flavor) of cloud node.

Image
: OS image used to burst the node.

1. Log in to PBS Cloud.
2. Click the Cloud tab.
3. Under Infrastructure, click Bursting.
4. Select a bursting scenario by clicking on its name.

   Any cloud nodes that have been burst are displayed under the Machines category.

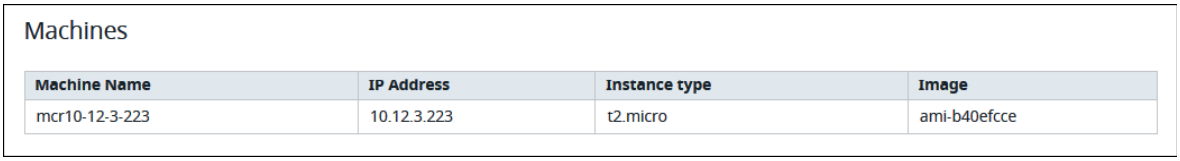

Figure 7-1:Burst Cloud Nodes

7.2.4 Enabling or Disabling a Bursting Scenario in PBS Cloud

Each bursting scenario is enabled by default when you create it.

1. Log in to PBS Cloud.
2. Click Cloud.
3. Click the Bursting tab on the left-hand side of the web page.
4. Select the name of the bursting scenario.
   - To enable the bursting scenario, click Enable.
   - To disable the bursting scenario, click Disable.

7.2.5 Disabling Bursting for a Scenario and Queue

How you stop the bursting process depends on whether the remaining jobs in the scenario queue can run using either the existing or edited scenario.

- If the jobs in the queue can run using the changed scenario:
  a. Stop the cloud queue associated with the scenario (prevent jobs in the queue from starting):
     qmgr -c "set queue <queue name> started=false"
  b. Allow the burst nodes for that scenario to drain and unburst, or requeue them
- If the jobs in the cloud queue must use the existing scenario:
  a. Disable the cloud queue (prevent jobs being enqueued):
     qmgr -c "set queue <queue name> enabled=false"
  b. Log in to PBS Cloud.
  c. Click Cloud.
  d. Click the Bursting tab on the left-hand side of the web page.
  e. Under Infrastructure, click Bursting.
  f. Select the name of the bursting scenario.
  g. Click Disable.
  h. Allow the cloud queue associated with the bursting scenario to drain; allow time for the jobs that are waiting in the queue to run and finish; allow automated unbursting to finish. You can shorten the time to unburst using the PBS Cloud interface or the PBS Cloud CLI.

Verify that all cloud nodes are unburst:

a. Click on the name of the cloud bursting scenario.
b. Look under the Machines heading. The following message indicates that all cloud nodes are unburst:
   `No machines are available`

7.2.6 Re-enabling Bursting for a Scenario and Queue

How you start the bursting process depends on how you stopped it.

- If you stopped the queue to prevent jobs from starting, start the cloud queue associated with the scenario (allow jobs to start):
  qmgr -c "set queue <queue name> started=true"
- If you disabled the queue to prevent jobs from being enqueued:
  a. Enable the cloud queue (allow jobs to be enqueued):
     qmgr -c "set queue <queue name> enabled=true"
  b. Log in to PBS Cloud.
  c. Click Cloud.
  d. Click the Bursting tab on the left-hand side of the web page.
  e. Under Infrastructure, click Bursting.
  f. Select the name of the bursting scenario.
  g. Click Enable.

7.3 Starting, Stopping, Restarting, and Statusing PBS Cloud

7.3.1 Start PBS Cloud

Starting PBS Cloud must be done as root or as a user with sudo permissions using the sudo command.

When your server hosting the PBS Cloud component reboots, containers are restarted automatically. If you need to manually start PBS Cloud containers, please follow the below instructions.

1. Log in to the machine where PBS Cloud is installed.
2. Enter the following command to start PBS Cloud:

```
pkr start
```

7.3.2 Stop PBS Cloud

Stop PBS Cloud after a manual installation.

Stopping PBS Cloud must be done as root or as a user with sudo permissions using the sudo command.

1. Log in to the machine where PBS Cloud is installed.
2. Enter the following command to stop PBS Cloud:

```
pkr stop
```

7.3.3 Restart PBS Cloud

Restarting PBS Cloud must be done as root or as a user with sudo permissions using the sudo command.

When your server hosting the PBS Cloud component reboots, containers are restarted automatically. If you need to manually restart PBS Cloud containers, please follow below instructions.

1. Log in to the machine where PBS Cloud is installed.
2. Enter the following command to restart PBS Cloud:

```
pkr restart
```

7.3.4 Determine the Status of PBS Cloud

Determine whether PBS Cloud is up or down.

1. Log in to the machine where PBS Cloud is installed.
2. Enter the following command to display the status of PBS Cloud:

```
pkr status
```

7.4 Monitoring Logs and Workflows

PBS Cloud includes a Loki interface for monitoring logs and workflows. To use this, log into PBS Cloud, then choose *Monitoring*, *Logs*, or *Workflows*.

The Monitoring section shows the status of the cloud services, including how many nodes are in the cloud, etc.

The Logs section shows all the PBS Cloud logs in chronological order.

The Workflows section shows you specific information about each workflow stage.

7.5 Updating PBS Cloud Administrator Password

We strongly recommend changing the administrator password after installing PBS Cloud.

Procedure to change PBS Cloud administrator password:

1. Log in to the PBS Cloud host as root
1. Run the following commands:

```
docker exec -ti guardian bash
source /opt/keystone_venv/bin/activate
openstack --os-identity-api-version 3 --os-auth-url http://localhost:4999/v3 --os-username
    altair_admin --os-password $ADMIN_PASSWORD --os-system-scope all user set --password <new
    password> pbsadmin
```

2. Type "exit" or ctrl-D to log out and close the connection to the container

7.6 Troubleshooting Cloud Bursting

Log messages can help you troubleshoot cloud bursting:

- Check log messages written to PBS_HOME/server_logs on the PBS server host.
- For debugging issues with node creation or issues with starting MoM on the cloud node, SSH to the cloud node and check PBS_HOME/mom_logs. This requires:
  - The Add Public IP to VMs scenario option is enabled; see section 3.3.4.2, “Temporarily Adding Public IP for Debugging”, on page 40
  - The SSH keys parameter has an administrator SSH key; see section 3.3.4.4, “Adding SSH Key for Access to Burst Nodes”, on page 41
- You can use PBS Cloud to view the logs through a Loki interface; see section 7.4, “Monitoring Logs and Workflows”, on page 166

7.6.1 PBS MoM is Stopped or Down

When you are using cloud bursting and all PBS MoMs are stopped or down, you may find error messages similar to the following in the PBS Server logs:

```
Server@server;Hook;Server@server;CLBR: Error: /opt/pbs/bin/pbsnodes: Server has no node list
Server@server;Hook;Server@server;CLBR: Error: Failed to get nodes info
```

Resolve the issue by starting at least one MoM.

7.6.2 Loki Logs

You can use the Loki logs to check the health of daemons/services. These logs collect information from daemons/services. Go to the Loki Home Page, choose the Explore option (the compass symbol), and select "Loki" from the menu. Enter your query in the query box. For more information, see https://grafana.com/oss/loki

7.6.3 Examining Node Bursting Workflows

A *workflow* is the process of bursting one or more nodes in the cloud. A workflow consists of a set of steps.

You can get useful debugging information by looking at workflow error messages returned by the cloud vendor. For each workflow step, you can see the request that PBS Cloud sent to the cloud provider, whether the step was successful, and information about the nodes that were burst. If the cloud vendor encountered an error while attempting a workflow step, PBS Cloud displays any error messages returned by the cloud vendor in the Outputs window for that step.

We recommend the following method for debugging workflows:

1. In PBS Cloud, click on the list of recent workflows.
2. In the "Filter" window, specify "error".
3. If necessary, you can sort by chronological order.

   (If you sort by state, the resulting list is not in chronological order.)
4. Click on the problematic workflow.

   The PBS Cloud window displays each step of the workflow down the left side.
5. To see the inputs and outputs for a step, click on it. The inputs and outputs for that step are displayed on the right side of the window. To see the inputs and outputs for steps that have a node tree icon, look for the same icon on the right side and click the down arrow next to it.

The "Input" window shows the request that PBS Cloud constructed and sent to the cloud provider.

The "Output" window shows a list of data about nodes that were burst for this workflow, including any errors returned by the cloud provider.

Icons above the Outputs window allow you to open the Inputs and Outputs windows in full-screen mode, and to copy the contents to the clipboard.

8 Managing Cloud Jobs

8.1 Managing Job Distribution to Cloud and On-premise Nodes

Your site may want to run certain types of jobs on-premise or in the cloud. PBS Professional provides various methods to collect and distribute jobs. For more information see "Routing Jobs" on page 204 in the PBS Professional Administrator's Guide.

To send jobs to the appropriate queue on submission, use hooks or routing queues. For more information see the *PBS Professional Hooks Guide* and "Routing Queues" on page 27 in the PBS Professional Administrator's Guide.

8.1.1 Running Cloud Jobs On-Premise When Possible

You may prefer to run jobs on-premise, but you may want to burst cloud nodes when you run out of on-premise capacity or need to get a job running sooner than it otherwise would.

You may want to use all, or a specific subset, of your on-premise nodes to run cloud jobs. To allow an on-premise node to be used for cloud jobs, we set the node's default_chunk.cloud_scenario resource to the list of scenarios allowed to run on this node. This is essentially overloading the meaning of the resource because no actual scenario is used; we're pseudo-bursting when we run a cloud job on this node. Each on-premise node can be assigned a list of scenarios so that it can run jobs from multiple cloud queues.

For each cloud queue whose jobs you want to run on-premise where possible, assign its bursting scenario to your selected on-premise vnodes by adding the value of the default_chunk.cloud_scenario queue resource to the list in the default_chunk.cloud_scenario vnode resource. Then those cloud jobs run on-premise when there is capacity, and cloud nodes are burst only when on-premise nodes are not available.

Use placement sets to make sure that each job runs entirely in-premise or in the cloud, but not in both places. For more information on placement sets, see "Placement Sets" on page 167 in the PBS Professional Administrator's Guide.

8.1.1.1 Steps to Run Cloud Jobs On-premise When Possible

For any on-premise vnodes where you want to run cloud jobs, assign one or more desired bursting scenarios to the vnode:

- To assign a list of bursting scenarios to a vnode:

```
qmgr -c "set node <vnode name> resources_available.cloud_scenario= <scenario 1>,<scenario
    2>,...<scenario N>"
```

- To assign a single bursting scenario to a vnode:

```
qmgr -c "set node <vnode name> resources_available.cloud_scenario= <scenario>"
```

For example:

```
qmgr -c "set node OnPrem1 resources_available.cloud_scenario=
    azure_scenario_1,aws_scenario_1,aws_scenario_2"
```

8.1.2 Job Distribution Examples and Solutions

8.1.2.1 Send Small Jobs to the Cloud

You have big machines for on-premise nodes and want to reserve those big machines for big jobs. You want to send smaller jobs to the cloud.

Solution 1:

- Create three queues: a routing queue, a local queue, and a cloud queue.
- Use the routing queue to collect jobs on submission.
- Set resource gating on the local queue to filter out smaller jobs.
- Allow smaller jobs into the cloud queue.

Solution 2:

- Create two queues: a local queue, and a cloud queue.
- Use a queuejob hook to route jobs into the appropriate queue.

8.1.2.2 Send Specific Jobs Only to the Cloud

You want to send specific jobs to the cloud because:

- an application needed by some jobs runs well in the cloud.
- a resource that is available in the cloud is not available locally.
- a department has exhausted its share of local resources, and wants to send its jobs to the cloud.

Solution :

- Create two queues: a local queue, and a cloud queue.
- Use a queuejob hook to route jobs into the appropriate queue.

8.1.2.3 Charge Departments for Resources Used

You have multiple departments and each department should be charged for the resources it uses.

Solution 1:

- Consider using PBS Budget to monitor consumption of on premise and cloud resources

Solution 2:

- Create a cloud queue for each department
- Set separate limits on each cloud queue

8.2 Allowing Easy Assignment of Jobs to On-premise or Cloud Nodes

8.2.1 Assigning Resources to Jobs Via Queue Defaults

You can move jobs back and forth between on-premise and cloud queues willy-nilly by using queue defaults. If you set the resources needed by cloud jobs as defaults at cloud queues, and the resources needed by on-premise jobs as defaults at on-premise queues, jobs inherit the resources they need to run in either place.

You can use queue defaults to set the resources requested by the jobs in a queue, for resources that are not explicitly requested by the job.

You can set default job-wide resources at a queue, which is the same as adding `-l <resource name>=<value>` to the job's resource request, and you can set chunk resources, which is the same as adding `:<resource name>=<value>` to each chunk.

You set job-wide resources via resources_default on the queue, and you set chunk resources via default_chunk on the queue.

You can also specify default placement of jobs via `-l place=free|pack|scatter|vscatter`.

8.2.1.1 Specifying Chunk Default Resources at Queue

To specify a queue-level chunk default resource, use the `qmgr` command to set the queue's default _chunk.<resource name> attribute:

qmgr -c 'set queue <queue name> default_chunk.<resource name>=<value>'

For example, if you want all job chunks that don't specify the OS image, network, or instance type to inherit specific values:

```
qmgr -c 'set queue cloud1 default_chunk.cloud_node_image="Image1"'
qmgr -c 'set queue cloud1 default_chunk.cloud_network="Network1"'
qmgr -c 'set queue cloud1 default_chunk.cloud_node_instance_type="Instance1"'
```

Make sure that default_chunk.cloud_node_instance_type matches the cloud_instance_type queue resource.

8.2.1.2 Specifying Job-wide Default Resources at Queue

To specify a default for a job-wide resource at a queue, use the `qmgr` command to set the queue's resources_default.<resource name> attribute:

qmgr -c 'set queue <queue name> resources_default.<resource name> = <value>'

For example, to have jobs in the cloud1 queue inherit a job-wide limit for one hour of walltime if they don't explicitly request walltime:

```
qmgr -c 'set queue cloud1 resources_default.walltime=1:00:00'
```

9 Example Azure Head/Service Node

9.1 Example Configuration of Cloud Head/Service Node in Azure

In this section we show an example of configuring a combined head and service node; it hosts both the PBS server and the PBS Cloud module. You would use this configuration for a smaller site.

Here we show an example of how to configure a PBS server host/PBS Cloud service node using Azure:

1. Create a new VM based on Centos 7, using Rogue Wave Software's CentOS-based 7.6 image, not an HPC tagged version
   - Use Standard_D14 instance type for head node (Good price/performance option)
   - Add additional storage: 1000GB SSD to allow an ext4 volume to be added; the Centos image uses XFS filesystem which has a bug with docker
2. Provide a public ssh key for the username "centos" via Azure GUI

   This is the only default user in this image
3. Once the node is up, use the provided external IP and your private key to connect to it. PuTTY is more robust for connection to cloud than Moba xTerm
4. Unless noted otherwise all the following commands must be run as root. Use sudo or the following to switch to the root user:

   ```
   sudo su -
   ```
5. Use `cfdisk` to partition `/dev/sdc` using all space for a single volume. Make absolutely sure that `/dev/sdc` is the right target. The target depends on instance type chosen and how many disks are added; if you followed the procedure exactly this should be correct in this case, but formatting is destructive to data on the disk.

   ```
   cfdisk /dev/sdc
   ```

   a. Select New

   b. Select Primary

   c. Accept Default Size (Should be whole disk)

   d. Select Write

   e. Answer yes (You will need to type yes)

   f. Select Quit
6. Create a filesystem on your drive (ext4 preferred):

   ```
   mkfs -t ext4 /dev/sdc1
   ```
7. Make a folder to mount your new volume to:

   ```
   mkdir /data
   ```

8. Set suitable permissions on the folder:

   chmod 777 /data

9. Find UUID from /dev/disk/by-uuid, e.g.

   ```
   lrwxrwxrwx 1 root root 10 Apr 1 12:48 640a03fd-aa69-4f8d-98d5-2f0d3d12bb26 -> ../../sdb1
   lrwxrwxrwx 1 root root 10 Apr 1 12:48 a505f591-5a7d-424f-a5a1-06dcb72f944c -> ../../sda1
   lrwxrwxrwx 1 root root 10 Apr 1 12:48 c6cd262b-3930-48a8-9b21-8981bb479cee -> ../../sdc1
   lrwxrwxrwx 1 root root 10 Apr 1 12:48 e0d6ff47-4c69-4a4c-b44a-13ea19d80f96 -> ../../sda2
   ```

10. Add a line to end of `/etc/fstab` for this mount (Note: ID of `/dev/sdc1` above):

    ```
    UUID=c6cd262b-3930-48a8-9b21-8981bb479cee /data ext4 defaults 0 0
    ```

11. Mount the new filesystem:

    mount /data

12. Upgrade all system packages to the latest versions:

    yum upgrade

13. Disable SELinux by editing `/etc/selinux/config` and changing, then save:

    ```
    SELINUX=enforcing -> SELINUX=disabled
    ```

14. Disable and stop `firewalld`

    systemctl disable firewalld
    systemctl stop firewalld

15. SELinux is still enforcing, so prevent that. Reboot.

16. Add password to user "centos":

    passwd centos

17. Log in as centos

18. Create ssh keys for centos and enable passwordless ssh

    Accept all the defaults for ssh-keygen step:

    cd $HOME
    ssh-keygen
    cd .ssh
    cat id_rsa.pub >> authorized_keys

19. For a cloud head node, make sure you validate that external ssh still works externally, before you disconnect your first session. If there is an issue with ssh keys, which can be sometimes caused by errors in step 18 above, and you disconnect your first session, you could be permanently locked out of your cloud VM. Use `ssh` from your local machine to your cloud head node to create a second session using your public `ssh` key. Troubleshoot as required while your first session is still up.

20. Add the key PBS Professional service users:

    useradd -rm pbsdata; useradd pbsadmin

21. Follow steps 17, 18, and 19 for user pbsadmin

22. Install/Start/Enable `docker-ce`

```
yum install -y yum-utils
yum-config-manager --add-repo https://download.docker.com/linux/centos/docker-ce.repo
yum install docker-ce docker-ce-cli containerd.io
systemctl enable docker
systemctl start docker
```

23. Stop `docker`:

```
systemctl stop docker
```

24. Move docker data storage to new filesystem mounted on /data

25. Add `-g /data/docker \` in file `/lib/systemd/system/docker.service`. `ExecStart` should look like this:

```
ExecStart=/usr/bin/dockerd-current ...
--seccomp-profile=/etc/docker/seccomp.json -g /data/docker $OPTIONS ...
$REGISTRIES
```

26. Reread daemon config files:

```
systemctl daemon-reload
```

27. Look in `/data/docker`; there should be subdirectories for Docker data

28. Start docker:

```
systemctl start docker
```

29. Create a repository for the PBS package:

```
mkdir /home/centos/software
chown -R centos:centos /home/centos/software
chmod 777 /home/centos/software
```

30. Download all the PBS package modules to your software directory (PBS Professional, PBS Cloud)

31. Install and configure NFS Server to share /home from head node, so you can avoid setting up ssh keys for client nodes and have a convenient mount:

```
yum install nfs-utils
systemctl enable nfs-blkmap
systemctl enable nfs-rquotad
systemctl enable nfs-server
systemctl enable nfs
systemctl start nfs-blkmap
systemctl start nfs-rquotad
systemctl start nfs-server
systemctl start nfs
```

32. Edit `/etc/exports` to add

```
/home *(rw,sync,no_root_squash,no_all_squash)
```

33. Restart NFS server:

```
systemctl restart nfs-server
```

34. Add local machine name and IP to /etc/hosts, remove IPv6 loopback, e.g.

```
127.0.0.1 localhost localhost.localdomain localhost4 localhost4.localdomain4
<PBS server IP address> <PBS server hostname>
```

This would look like:

```
127.0.0.1 localhost localhost.localdomain localhost4 localhost4.localdomain4
172.17.0.6 myhost
```

35. Follow the *PBS Professional Installation & Upgrade Guide*, the *PBS Professional Administrator's Guide,* and the *PBS Professional Licensing Guide* to install, configure and license PBS Professional

- Set PBS to have MoM running on the head node before first start

36. Run test job and ensure job output is returned without issues (e.g. scp problems)

Sample test script using cloudq:

```
#!/bin/bash
#PBS -N testjob
#PBS -j oe
#PBS -m n
#PBS -q cloudq
#PBS -l select=1:ncpus=2:mem=16mb
#PBS -l walltime=0:10:00
sleeptime=60
cmd="sleep $sleeptime"
echo $cmd
$cmd
Exit
```

10 Command Reference

10.1 PBS Cloud PCLM Command-line Interface

As of version 2021.1.3, the `pclm` command-line interface is **deprecated**.

10.1.1 Introduction

10.1.1.1 Bursting Scenarios

You create each cloud bursting scenario via PBS Cloud. Each scenario provides information needed for cloud bursting including the cloud provider, region where nodes are burst, VPC details, the cloud node booting script, SSH keys, valid instance types, etc.

10.1.1.2 Bursting Scenario States

READY
: When the bursting scenario is enabled, it can be used to burst nodes

: When the bursting scenario is disabled, it could be used to burst nodes if you enabled it

PENDING
: The scenario is added but not validated

BUSY
: The bursting or unbursting workflow is running; we are in the process of bursting or unbursting

DELETING
: The bursting scenario is being deleted

ERROR
: The bursting scenario contains an error

10.1.1.3 PBS Cloud Account States

READY
: The account is ready and usable

PENDING
: Your login credentials are being validated with the cloud vendor

BUSY
: The account is busy

DELETING
: The account is being deleted

ERROR
: The account contains an error

10.1.1.4 Cloud Node States

The following is a list of possible instance states. Only an instance that is UP is guaranteed to have an IP address and a hostname. An instance that has been fully unburst will not appear in the output at all.

DOWN
: Instance is created in the local database, but not yet in the cloud provider. This status is short-lived and rarely visible.

DEPLOYING
: Instance is in the process of being deployed

FAILED_DEPLOYING
: Something has gone wrong and the instance deployment has failed. The instance is automatically unburst in this case

FAILED_STARTING
: Something has gone wrong and the instance has not started

FAILED_STOPPING
: Something has gone wrong and the instance has not been stopped

FAILED_TERMINATING
: Something has gone wrong and the instance has not been terminated

STARTING
: Instance is starting

STOPPED
: Instance is stopped

STOPPING
: Instance is stopping

TERMINATING
: Instance is being removed.

UP
: Instance is deployed and ready

10.1.1.5 Some Outputs of PCLM Commands

Burst identifier
: Unique numeric identifier returned from burst request.

Cloud node hostname
: Hostname assigned to the cloud node. Find this using the command to display cloud node details described in section 10.1.3.3, “Displaying Cloud Node Details”, on page 181

Machine ID
: Unique label that identifies the cloud node. Find this using the command to display cloud node details described in section 10.1.3.3, “Displaying Cloud Node Details”, on page 181

Private IP
: Private IP address assigned to the cloud node. Find this using the command to display cloud node details described in section 10.1.3.3, “Displaying Cloud Node Details”, on page 181

Scenario ID

Unique label that identifies a bursting scenario. Required to enable, disable or get the status of a bursting scenario. Use the command to display a list of bursting scenarios described in section 10.1.2.3, “Displaying a List of Bursting Scenarios”, on page 179 to obtain a list of bursting scenarios including the scenario ID.

10.1.1.6 Options to the pclm Command

--raw

Displays the output of the command in JSON format.

This option must be the first option after the `pclm` command itself. For example:

```
pclm --raw --api-endpoint==http://<PBS Cloud hostname or IP address>:<PBS Cloud
    port>/pbspro-cloud/ --api-key <API key>
```

--wait

The application waits for the node to be burst or unburst.

This option must be the first option after the `bootstrapper` option. For example:

```
pclm --api-endpoint=http://<PBS Cloud hostname or IP address>:<PBS Cloud port>/pbspro-cloud/
    --api-key <API key> bootstrapper --wait scenario burst
```

10.1.2 CLI Scenario Commands

In this section we describe the PCLM command-line interface commands that you can use to get information such as status about existing bursting scenarios, to enable a bursting scenario so that nodes can be burst, to disable a bursting scenario to restrict nodes from being burst, etc.

10.1.2.1 Enabling a Bursting Scenario

To enable a bursting scenario so that cloud nodes can be burst using the scenario.

```
pclm --api-endpoint=http://<PBS Cloud host name or IP address>:<PBS Cloud port>/pbspro-cloud/
    --api-key <API key> bootstrapper scenario enable <scenario ID>
```

To verify that the bursting scenario is enabled, use the command to display bursting scenario details described in section 10.1.2.4, “Displaying Bursting Scenario Details”, on page 180.

10.1.2.2 Disabling a Bursting Scenario

Cloud nodes cannot be burst using a scenario that is disabled.

To disable a bursting scenario:

```
pclm --api-endpoint=http://<PBS Cloud host name or IP address>:<PBS Cloud port>/pbspro-cloud/
    --api-key <API key> bootstrapper scenario disable <scenario ID>
```

To verify that the bursting scenario is disabled, use the command to display bursting scenario details described in section 10.1.2.4, “Displaying Bursting Scenario Details”, on page 180.

10.1.2.3 Displaying a List of Bursting Scenarios

To display a list of bursting scenarios created using PBS Cloud:

```
pclm --api-endpoint=http://<PBS Cloud host name or IP address>:<PBS Cloud port>/pbspro-cloud/
    --api-key <API key> bootstrapper scenario list
```

The output of the command is a list of bursting scenarios including the scenario ID, the state of the scenario, and whether the scenario is enabled or disabled.

10.1.2.4 Displaying Bursting Scenario Details

To get information about the bursting scenario:

```
pclm --api-endpoint=http://<PBS Cloud host name or IP address>:<PBS Cloud port>/pbspro-cloud/
    --api-key <API key> bootstrapper scenario show --id <scenario ID>
```

The output of the command displays information about the bursting scenario including the scenario ID, the state of the scenario, the associated cloud account. and whether the scenario is enabled or disabled.

To display the amount of time before an idle node is unburst:

```
pclm --raw --api-endpoint=http://HOST:9980/pbspro-cloud/ --api-key KEY bootstrapper scenario show
```

The --raw argument is required.

The output of the command is in a JSON format. The idle time is displayed as a key-value pair in the output. Example:

```
{"idle_before_unburst": 100}
```

10.1.2.5 Setting Minimum Time Before Unbursting Idle Node

We recommend setting the Idle Before Unburst scenario parameter to more than double the PBS scheduler cycle time.

To set the minimum time that a cloud node can be idle before it is unburst:

```
pclm --api-endpoint=http://<PBS Cloud host name or IP address>:<PBS Cloud port>/pbspro-cloud/
    --api-key <API key> bootstrapper scenario patch --idle-before-unburst <max idle time before
    unbursting> <scenario ID>
```

To verify that the idle before unburst time is updated, use the command to display bursting scenario details, and include the `--raw` option. We describe the command in section 10.1.2.4, “Displaying Bursting Scenario Details”, on page 180.

10.1.3 CLI Node Commands

In this section we describe the `pclm` command-line interface commands that you can use to burst and unburst cloud nodes, and to get status information about a bursting activity.

You can use these commands for the following:

- Testing cloud bursting without using the cloud bursting hooks
- Checking connectivity between the PBS server and the cloud infrastructure
- Checking whether bursting scenarios are working properly
- Bursting a cloud node so that it remains burst indefinitely

Cloud nodes that are manually burst remain up and running until explicitly unburst.

10.1.3.1 Bursting Cloud Nodes

To burst <burst_count> cloud nodes of type <instance type> for the bursting scenario identified by <API key>:

```
pclm --api-endpoint=http://<PBS Cloud host name or IP address>:<PBS Cloud port>/pbspro-cloud/
    --api-key <API key> bootstrapper --wait scenario burst '{"mom":[{"deployable_id":"<instance
    type>","count":"<burst count>","tags":{"burst-by":"user"}}]}'
```

The PBS cloud bursting hooks always add a tag named "burst-by" and set its value to "pbs-cloudhook".

You can use the same tag with a different value, or a different tag altogether, to distinguish manually burst nodes from those burst via the cloud bursting hooks.

You can describe the type of node to burst and how many to burst by including JSON instructions directly on the command line, as shown above, or by loading it from a separate file. For example, you can copy the following JSON to a file called node_to_burst.json:

```
{"mom":[{"deployable_id": "<instance type>", "count":"10", "tags": {"burst-by": "user"}}]}
```

Then you can use the file in the bursting command to load the information:

```
pclm --api-endpoint=http://<PBS Cloud host name or IP address>:<PBS Cloud port>/pbspro-cloud/
    --api-key <API key> bootstrapper --wait scenario burst node_to_burst.json
```

10.1.3.2 Unbursting Cloud Nodes

You can unburst a cloud node using its machine ID, private IP address, or hostname. To unburst cloud nodes:

pclm --api-endpoint=http://<PBS Cloud host name or IP address>:<PBS Cloud port>/pbspro-cloud/ --api-key <API key> bootstrapper --wait scenario unburst <machine ID1>|<private IP address1>|<cloud node hostname1> <machine ID2>|<private IP address2>|<cloud node hostname2> [...]

You can unburst multiple nodes in a single call, and you can mix the parameter you use to unburst the nodes:

unburst <machine ID1> <private IP address2> <cloud node hostname3>

You can supply this information in JSON format on the command line or in a JSON file:

```
unburst '["<machine ID1>", "<private IP address2>", "<cloud node hostname3>"]'
unburst /tmp/machines_to_unburst.json
```

To get information about cloud nodes, use the command to display cloud bursting activity described in section 10.1.3.3, “Displaying Cloud Node Details”, on page 181.

10.1.3.3 Displaying Cloud Node Details

To display details for cloud nodes, use the `status` command:

```
pclm --api-endpoint=http://<PBS Cloud hostname or IP address>:<PBS Cloud port>/pbspro-cloud/
    --api-key <API key> bootstrapper scenario status -f tags
```

The status command displays node status details in a table with the machine ID, instance type, hostname, private and public IP addresses, the OS image used to create the node, the node's state, and its creation time.

To display the output in JSON format, use the `--raw` option.

To display any associated tags, use the `-f tags` option.

Example of output:

```
(pclm-cli-env)$ pclm $API bootstrapper scenario status -f tags
+--------------------------------------+---------------+-------------+------------+-------------+-------------------------------+-------+----------------------+-----------------------+
|              machine_id              | instance_type |   hostname  | private_ip |   public_ip |           os_image            | state | workflow_created_at |         tags          |
+--------------------------------------+---------------+-------------+------------+-------------+-------------------------------+-------+----------------------+-----------------------+
| 71b1f132-3a5d-42fc-9f25-16311e4b0ca2 | Standard_B1ls | nodea000003 |  10.0.0.7  | 52.168.88.253 | pclm-centos7.4-hpc-cloud-init |   UP  | 2019-09-26 10:50:03 | {u'burst-by': u'user'} |
| f4c6e65b-6631-4571-8bfe-72d43c1c82e5 | Standard_B1ls | nodea000002 |  10.0.0.6  | 52.168.88.231 | pclm-centos7.4-hpc-cloud-init |   UP  | 2019-09-26 10:50:03 | {u'burst-by': u'user'} |
+--------------------------------------+---------------+-------------+------------+-------------+-------------------------------+-------+----------------------+-----------------------+
```

Figure 10-1:status Command Output

10.1.3.4 Defining Network Disk Size for Cloud Node Root System

Use the disk_size_gb parameter to define the size of the network disk for the root filesystem in GBs when bursting a cloud node. By default the minimum size is compatible with the image associated with the bursting scenario defined by <API key>.

```
"mom" : [
    {
        "deployable_id": "c3.xlarge",
        "disk_size_gb": 12
    },
    {
        "deployable_id": "d2.xlarge",
        "count": 2,
        "disk_size_gb": 15
    }
]
```

10.1.3.5 Specifying Image to Use when Bursting

You can manually burst an instance from a specific image using the image parameter. Every bursting scenario has a default image which is used for bursting if the image is not explicitly specified. The value of image depends on the cloud provider. For example, for AWS you specify the name of the AMI:

```
"mom":[{"deployable_id": "t2.medium", "count":"10", "image":"ami-123456"}]
```

For Azure, you specify the resource group into which to place the instance and the name of the image:

```
"mom":[{"deployable_id": "Standard_DS1_v2", "count":"10", "image":"res-group/imagename"}]
```

10.1.3.6 Providing Nodes on High Speed Networks

Job submitters may want to run HPC workloads such as MPI jobs on groups of nodes connected by a high speed switch. A job cannot run across multiple Infiniband networks. Only instances within the same scale set have high speed connectivity. The cloud provider can burst a group of nodes on the same high speed network. For example, Azure provides scale sets and Oracle provides instance pools.

In the following instructions, the command uses terms such as "infiniband" and "scaleset"; nevertheless, the command works with other supported high speed switches and providers.

Use the infiniband_network parameter to ensure that all nodes for a bursting request are deployed into the same scale set or instance pool.

Make sure that the OS image used for bursting Infiniband nodes contains everything that is needed to use the high speed network.

You need to provide the correct instance types and placement sets; see section 3.4, “Providing Nodes Grouped on High Speed Network”, on page 48.

You can either create a new scale set or instance pool, or add to an existing one. However, it is highly unlikely that adding to an existing scale set or instance pool will succeed, especially for high speed networks. (The cloud bursting hooks always create a new group of nodes.)

- To create a new group of nodes on a high speed switch, set the value of the infiniband_network parameter to "*new*":

  ```
  "deployable_id":"Standard_H16mr", "infiniband_network": "new"
  ```

- To use an existing group of nodes on a high speed switch, set the value of the infiniband_network parameter to "*auto*", which will re-use the existing groups as long as all requested nodes fit inside the group. If they do not, a new group is created for the requested nodes.

  ```
  "deployable_id":"Standard_H16mr", "infiniband_network": "auto"
  ```

Use the command in section 10.1.3.3, “Displaying Cloud Node Details”, on page 181 to display the status of the cloud bursting activity to get information about a node's group (scale set, instance pool, etc.). For example:

```
{ ...,
    "scaleset": {"nr": "2", "name": "pclmDEVvhoiAACrxTOHioWSkwg"}, ... }
```

Nodes with the same name value are in the same group. Each scenario is tagged with its own API key.

10.1.3.7 Bursting Asynchronously

Sometimes it can take several minutes to burst a cloud node. If you do not want to wait for the bursting command to complete, eliminate the `--wait` option and provide a unique request identifier. The bursting call returns a unique *request identifier*.

```
pclm --api-endpoint=http://<PBS Cloud host name or IP address>:<PBS Cloud port>/pbspro-cloud/
    --api-key <API key> bootstrapper scenario burst --request-id <burst identifier>
    '{"mom":[{"deployable_id": "<instance type>", "count":"<burst count>"}]}'
```

10.1.3.8 Querying Bursting Activity

When you make a burst request, the `pclm` command returns a unique *burst identifier*.

Using the burst request identifier to determine status of the burst request:

```
pclm --raw --api-endpoint==http://<PBS Cloud host name or IP address>:<PBS Cloud
    port>/pbspro-cloud/ --api-key <API key> notif thread list --request-id <burst identifier>
    --expand
```

Output from the status query will look something like this:

```
[
    {
        "title": "Workflow bootstrapper.deploy_deployables",
        "created_at": "2022-10-01T09:02:57.383000+00:00",
        "open": false,
        "related": [ ... ],
        "notifications": [
            ... ,
            {
                "notification_id": "5d93170000b64a0001c4fe00",
                "sender": "executor",
                "message": "Workflow \"deploy_deployables\" execution succeeded",
                "timestamp": "2022-10-01T09:06:08.752000+00:00",
                "content": {
                    "workflow": "deploy_deployables",
                    "workflow_name": "bootstrapper.deploy_deployables",
                    "machine_ids": [
                        "a8d1681f-173d-4476-9d52-05e7e1b405d5",
                        "535ec0fc-f6f4-4b51-8f9d-abb13984f42d"
                    ],
                    "state": "SUCCEEDED",
                    "machines": [ ... ],
                    ... ,
                },
                ...
            }
        },
    ],
    ...
}
```

While the asynchronous bursting command is running, open is *true* and state is *RUNNING*.

When the asynchronous bursting command has finished all operations, open is *false* and state is set to *SUCCEEDED* or *FAILED*.

10.1.3.9 Bursting Preemptable Instances

We describe how to use spot and preemptable instances is in section 3.3.5, “Using Spot or Preemptable Pricing”, on page 46. To use `pclm` to burst preemptable instances:

- Use the `preemptable` parameter to burst preemptable or spot instances. This parameter takes a Boolean value.
- Make sure that the bursting request contains only preemptable instances or only non-preemptable instances.
- Make sure that the bursting scenario associated with the selected API key has "spot instances" enabled.

For example:

```
pclm --api-endpoint=http://<PBS Cloud host name or IP address>:<PBS Cloud port>/pbspro-cloud/
    --api-key <API key> bootstrapper --wait scenario burst "mom":[{"deployable_id":
    "c3.xlarge","count":"10","preemptable": true}]
```

10.2 PBS Cloud pkr Interface

10.2.1 Using pkr with PBS Cloud

A *kard* defines all the container images and container services you need for PBS Cloud. Each kard is specific to its version of PBS Cloud. This version of PBS Cloud comes packaged with the PBS Cloud kard already fully defined. The PBS administrator is not expected to make any changes to the kard.

We use `pkr` to manage all the containers in the current kard, which in this context means all the services around the Cloud Bursting feature in PBS Professional. Each service runs in its own container.

To start all `pkr` services:

```
pkr start
```

To stop all `pkr` services:

```
pkr stop
```

To list all `pkr` services:

```
pkr ps
```

10.2.2 Sample pkr Output on Startup

```
[root@myhost ~]# pkr start
Starting postgres      ... done
Starting mongodb       ... done
Starting cadvisor      ... done
Starting loki          ... done
Starting fluentd       ... done
Starting prometheus          ... done
Starting fluentd             ... done
Starting bootstrapper-worker  ... done
Starting bootstrapper-worker1 ... done
Starting grafana             ... done
Starting guardian            ... done
Starting notification-center  ... done
Starting websocket-bridge    ... done
Starting pacioli             ... done
Starting keeper              ... done
Starting hype                ... done
Starting hubble              ... done
Starting mistral-api         ... done
Starting ui                  ... done
Starting executor-api        ... done
Starting mistral-executor    ... done
Starting cloudflow           ... done
Starting bootstrapper-api    ... done
```

10.2.3 Sample pkr Output on Stop

```
[root@myhost ~]# pkr stop
Stopping bootstrapper-api     ... done
Stopping cloudflow            ... done
Stopping ui                   ... done
Stopping mistral-executor     ... done
Stopping executor-api         ... done
Stopping keeper               ... done
Stopping notification-center  ... done
Stopping pacioli              ... done
Stopping websocket-bridge     ... done
Stopping hype                 ... done
Stopping mistral-api          ... done
Stopping hubble               ... done
Stopping guardian             ... done
Stopping grafana              ... done
Stopping bootstrapper-worker1 ... done
Stopping bootstrapper-worker  ... done
Stopping prometheus           ... done
Stopping fluentd              ... done
Stopping node-exporter        ... done
Stopping postgres             ... done
Stopping rabbitmq             ... done
Stopping loki                 ... done
Stopping mongodb              ... done
Stopping cadvisor             ... done
```

10.2.4 Sample pkr Output while Running

System is running:

```
[root@myhost ~]# pkr ps
- cadvisor: 172.18.0.4
- loki: 172.18.0.6
- fluentd: 172.18.0.9
- mongodb: 172.18.0.3
- node-exporter: 172.18.0.5
- postgres: 172.18.0.2
- prometheus: 172.18.0.8
- grafana: 172.18.0.12
- rabbitmq: 172.18.0.7
- guardian: 172.18.0.13
- pacioli: 172.18.0.14
- notification-center: 172.18.0.16
- mistral-api: 172.18.0.20
- mistral-executor: 172.18.0.23
- keeper: 172.18.0.17
- hype: 172.18.0.18
- hubble: 172.18.0.19
- executor-api: 172.18.0.22
- cloudflow: 172.18.0.24
- bootstrapper-worker1: 172.18.0.10
- bootstrapper-worker: 172.18.0.11
- bootstrapper-api: 172.18.0.25
- websocket-bridge: 172.18.0.15
- ui: 172.18.0.21
```

A missing IP address indicates that a service is unhealthy, although an IP address does not guarantee health.

10.2.5 Sample pkr Output while Stopped

System is stopped:

```
[root@myhost ~]# pkr ps
- cadvisor: stopped
- loki: stopped
- fluentd: stopped
- mongodb: stopped
- node-exporter: stopped
- postgres: stopped
- prometheus: stopped
- grafana: stopped
- rabbitmq: stopped
- guardian: stopped
- pacioli: stopped
- notification-center: stopped
- mistral-api: stopped
- mistral-executor: stopped
- keeper: stopped
- hype: stopped
- hubble: stopped
- executor-api: stopped
- cloudflow: stopped
- bootstrapper-worker1: stopped
- bootstrapper-worker: stopped
- bootstrapper-api: stopped
- websocket-bridge: stopped
```

Contents

1 Introduction to Budgets

1.1 Using Budgets to Track, Reveal, and Manage Resource Use

Budgets allows you to track and manage credit and other resources for jobs at PBS complexes. You can define and track multiple currencies, and these can be any form of currency you need: dollars, CPU hours, GPU hours, etc. You can define how you want each currency calculated separately for on premise and cloud jobs at each PBS complex .

Budgets can provide a job submitter with an estimate for the cost of an on premise or cloud job. You can require that the owner of a job has sufficient credit to run a job, including checking credit before bursting cloud nodes.

Using Budgets, you can see how resources are being used at your site, and you can manage how those resources are used.

1.1.1 Two Modes: Postpaid and Prepaid

Budgets has two modes:

- In *postpaid mode*, Budgets tracks resource usage by users and projects, according to the criteria you define, but does not enforce limits. You use postpaid mode to understand how users and projects use resources, and how much they need. In postpaid mode, users do not need credit to run jobs. In postpaid mode, job submitters owe a positive number, similar to the way a credit card bill shows that a positive amount is owed.
- In *prepaid mode*, Budgets enforces usage limits; users need sufficient credit to run each job. You use prepaid mode to keep resource allocations within desired bounds. In prepaid mode, the amount of credit remaining in a job submitter's account is a positive number, and the amount debited for each job is a negative number.

The mode is global and applies to all of Budgets. You can switch back and forth between modes.

1.1.2 Using Postpaid Mode to Validate Jobs and Understand Resource Usage

Postpaid mode behaves as if your users and projects are charging everything to a credit card that never demands payment. They accumulate a credit balance. They can pay down the balance as they go, but that is not required for them to run jobs. The Budgets administrator can provide partial or full refunds if necessary.

This mode allows users and projects to run jobs without having been assigned a credit balance. However, you can use this balance as a basis for charging users, if your site charges users for resources.

Using postpaid mode, you can get detailed reporting about the amount of resources used by each user and project submitting jobs. In postpaid mode, Budgets provides reporting only for top-level time periods.

You can use postpaid mode to make sure that users and jobs are validated before jobs run.

In postpaid mode, Budgets adds the cost for a job to the job owner's account after the job runs.

1.1.2.1 Job Flow in Postpaid Mode

1. A job is submitted
2. Budgets checks the following:
   - Whether the submitter is associated with the cluster where the job is submitted
   - Whether any quotas have been exceeded
   - If a job is submitted as part of a project, whether the submitter is associated with the project

   If the submitter and job pass all of these tests, PBS allows the job to be enqueued
3. The job runs
4. After the job runs, Budgets adds the cost for the job to the job submitter or project credit balance

1.1.3 Using Prepaid Mode to Validate Jobs and Manage Credit and Costs

You represent each department in your organization as a group in Budgets. Each department receives investment which it can then spend on projects and individual users. Funding allocations apply to, are charged against, and are tracked in time periods. Every transaction is available for examination forever.

You can require that job owners have sufficient credit to run each job before allowing that job to be queued, or you can let jobs with insufficient credit be queued and remain there until the owner has sufficient credit to run them.

Before a job runs, Budgets checks that the job owner has enough currency to run the job, then transfers that amount from the job owner's account into escrow. After the job runs, Budgets reconciles charges for the job: it debits escrow for the amount consumed by the job and returns any excess to the job owner, or if the job consumed more than requested it debits more from the job owner's account. The Budgets administrator can provide partial or full refunds if necessary.

Budgets is flexible; a department can fund multiple projects and users working in multiple PBS complexes. A project or user can be funded by multiple departments and run jobs in multiple PBS complexes.

1.1.3.1 Managing Job Submission and Execution in Prepaid Mode

When you manage a PBS complex via Budgets in prepaid mode, each PBS job can run only when the job can be charged to a project or user account that has sufficient credit. The organization's CFO can fund a group representing a department or other organizational entity; this group can then deposit credit with project or user accounts.

A project spends credit when a user associated with the project runs a job and charges the job to the project account. A job can be charged to a project account only when it is run by an associated user on an associated complex. Any user associated with the project can charge a job to the project account.

An individual user spends credit when they run a job and charge it to their own account. This job must be run on a complex that is associated with the user.

When a group manager deposits group credit to a project account, that allocation is for a specific period and in a specific currency (service unit). Currency is usually defined as resource usage, such as CPU hours or GPU hours, but can be in dollars or other monetary units.

In addition to checking credit balances, Budgets checks whether a job owner has hit any quotas for externally-managed resources such as storage, using a mechanism called *dynamic service units*. See section 1.7.2.2, “Dynamic Service Units”, on page 19.

In prepaid mode, Budgets subtracts the estimated cost of each job from the job submitter or project credit balance before the job runs, then reconciles any difference after the job runs.

You can ensure that cloud jobs run only when the owner has sufficient credit. See section 3.2.7, "Requiring Sufficient Credit Before Bursting Cloud Nodes", on page 72.

1.1.3.2 Job Flow in Prepaid Mode

1. A job is submitted
2. Budgets checks the following:
   - Whether the submitter is associated with the cluster where the job is submitted
   - Whether any quotas have been exceeded
   - If a job is submitted as part of a project, whether the submitter is associated with the project
   - If AM_BALANCE_PRECHECK is set to *True* in the Budgets configuration file, whether the job submitter has sufficient credit to run the job
     - If there is sufficient credit, the job is enqueued
     - If there is not sufficient credit, the job is rejected by PBS
   - If AM_BALANCE_PRECHECK is set to *False* in the Budgets configuration file, whether the job submitter has sufficient credit to run the job
     - If there is sufficient credit, the job is enqueued
     - If there is not sufficient credit, the job is enqueued with a comment noting the insufficient credit
3. The scheduler selects the job to run
4. Budgets checks the following:
   - Whether the submitter is associated with the cluster where the job is submitted
   - Whether any quotas have been exceeded
   - If a job is submitted as part of a project, whether the submitter is associated with the project
   - Whether the job submitter has sufficient credit to run the job
     - If the submitter does not have enough credit, the job is returned to the queue
5. If the submitter has enough credit:
     - Budgets reserves the full amount of credit estimated to run the job
     - The job runs
6. After the job runs, Budgets reconciles the actual cost to run the job with the reserved credit, and returns any overage to the submitter

When AM_BALANCE_PRECHECK is set to *False* in the Budgets configuration file, Budgets keeps creditless jobs in the queue so that they will run as soon as the job submitter has sufficient credit; the job submitter does not need to resubmit or remove a hold from these jobs.

When AM_BALANCE_PRECHECK is set to *True* in the Budgets configuration file, PBS rejects any creditless jobs. These jobs must be resubmitted when the job submitter has sufficient credit.

1.1.4 Tracking Cloud Costs and On Premise Costs Separately

You can treat all jobs as if they will run on premise, using the same formulas for all jobs. However, you can instead use cloud-specific cost data in formulas designed specifically for cloud jobs, while using on premise formulas for on premise jobs. You can collect cloud instance cost data and give it to Budgets, and Budgets can use it when computing cloud-based billing costs. This way, you can track and charge for cloud costs separately from on premise costs. See section 3.2.6, “Separating On Premise and Cloud Costs”, on page 71.

You can use and manage cloud cost information separately from on premise cost information:

- You can keep Budgets informed about the cost per unit time for each cloud instance. You collect the cost information from the cloud provider, then use the `amgr update clouddata` command to give this information to Budgets. You may find it helpful to do this in a `cron` job or periodic hook. See section 4.2.3.10, “Updating Cloud Cost Data”, on page 98.
- You can see the cloud cost data that has been given to Budgets via the `amgr ls clouddata` command. See section 4.2.2.10, “Listing Cloud Data”, on page 90.
- You can create separate formulas for cloud-specific service units so that you can track cloud job costs. Budgets can use the data you gave it for each specific instance when calculating the cost for a job that will use that instance. You can also create formulas that combine on premise and cloud costs when you need to calculate total credit usage for a job owner. See section 3.2.3.3, “Defining Cloud and On Premise Service Units”, on page 65.
- You can specify that each cloud job can burst cloud nodes only when the job owner has sufficient credit, as calculated by Budgets. See section 3.2.6, “Separating On Premise and Cloud Costs”, on page 71.
- The administrator and the job owner can check whether that job owner has sufficient credit to run a job via the `amgr precheck` commands. See section 4.3.4, “Prechecking Service Unit Balance”, on page 124.

1.1.5 Recommendation: Start Using Budgets in Postpaid Mode

We recommend starting with postpaid mode, especially if you are already running jobs, so that you can get an idea of usage needs and patterns. In postpaid mode, you do not need to allocate credit to users and projects, and they can run jobs right away. If you need to enforce limits, you can switch to prepaid mode. In prepaid mode, you do need to allocate credit before jobs can be run.

If you want to begin using Budgets in prepaid mode but have not used such tools before, be aware that there are some steps to define the business processes you will use to manage credit, and some calibration to understand the amount of credit to provide to users and projects. It is important to get these steps right, because providing too little credit to users and projects could prevent the site workload from running.

We recommend that you begin by using Budgets in postpaid mode for a meaningful period of time (e.g. a quarter, especially if you manage credit per quarter) which will give you data you can use to guide your investments later in prepaid mode.

The easiest point at which to transition from postpaid to prepaid mode is on the boundary of a time period. For example if you are in Q1 and you have sufficient data to make your future investment decisions, you can make the transition between Q1 and Q2: before the end of Q1 you can pre-invest in Q2 users and projects, and then switch modes at the end of Q1.

1.2 Some Nuts and Bolts

1.2.1 The AMS Module

The AMS module provides the security framework for Budgets. Budgets uses AMS to retrieve tokens, verify them, and authenticate users. When you install Budgets, the Budgets server is registered as a client of AMS. Every Budgets request has an authorization token.

1.2.2 Number of Instances and Workers

A large site will probably find that a single instance of Budgets for all PBS complexes works best. With a single instance of Budgets, you can use a different charging model for each PBS complex.

Budgets is web-based for scalability. By default, the number of workers is two; you can spawn more if you need to.

1.2.3 Hooks and Formulas

Budgets is tightly integrated with the job management mechanisms of PBS Professional.

Budgets uses hooks to calculate billing at each PBS complex. Budgets uses two hooks, am_hook and am_hook_periodic, that are identical except for their triggering events, that are installed in the PBS complexes. These hooks calculate service unit consumption using the billing formulas defined in the formula file, which is used as the hook configuration file. You can define the formulas to be based on compute resources, time, day of week, time of day, priority of queue, etc. See section 3.2.3, “Define Billing Formulas”, on page 62.

1.2.4 Database

Budgets uses a Postgres database.

1.2.5 Budgets and PBS Cloud

Budgets and PBS Cloud are integrated so that Budgets can use cloud cost data to calculate costs for cloud jobs and track credit. Budgets can make sure that each cloud job owner has sufficient credit before allowing a cloud job to burst cloud nodes.

1.3 Budgets Terminology

Account

Budgets has user, project, and group accounts. See User, User Account, Project, Project Account, and Group, Group Account.

Accounting Policy

A policy associated with a project or user. Can be any of *begin_period*, *end_period*, or *proportionate*.

Active or inactive

An active element can perform all its normal functions; an inactive element cannot run jobs or do transactions.

Allocation

A specified amount of one or more service units designated for use by a project or user. An allocation exists for a fixed time period. As the service units are consumed, the allocation is depleted. Allocations can be made for compute resources, budget resources, time resources, or a combination of those.

AMS

Security module used by Budgets to retrieve tokens, verify them, and authenticate users.

Billing Formulas

An arithmetic formula defining how a service unit is charged at a PBS complex. This is typically a PBS resource and time, for example, the PBS resource ncpus multiplied by walltime defines the service unit for CPU hours. Other examples are GPU hours, memory hours, etc. The billing formulas for each PBS complex are defined in the Budgets hook configuration file for that complex. See section 3.2.3, "Define Billing Formulas", on page 62.

Cluster

A data structure representing a PBS complex. Named for the PBS server. See section 1.7.5, "Clusters", on page 23.

Element

Blanket term used to refer to a part of Budgets, such as an account, a transaction, a role, etc. Can be an entity or something associated with an entity, such as a limit on a service unit.

Entity

Data structure representing a part of Budgets: a period, cluster, service unit, user, project, or group.

Group, Group Account

Entity representing an organizational structure such as a department, business unit, etc. A group account has a credit balance, at least one associated investor who invests service units in the group account, and at least one associated manager who uses the group account to fund users and projects.

Instance

An installation of Budgets; described by a name and the hostname or IP address of the machine where Budgets is installed.

Mode

Budgets runs in either postpaid or prepaid mode. In postpaid mode, job submitters do not need credit to run jobs. In prepaid mode, job submitters need credit to run jobs. The mode is global and applies to all of Budgets.

PBS complex

An installation of PBS Professional consisting of daemons including a server daemon and at least one MoM daemon, and the hosts on which those daemons run. The name for a PBS complex is the name of its server daemon, which is found in PBS_SERVER parameter in the `/etc/pbs.conf` file.

Periods, Allocation Periods, Billing Periods

Time period. Budgets can use a hierarchical system of time periods.

Postpaid Mode

In postpaid mode, job submitters do not need credit in order to run jobs.

Prepaid Mode

In prepaid mode, job submitters must have sufficient credit in order to be able to run jobs.

Project, Project Account

Entity representing a project, for example a workflow, as well as its associated account, including its credit balance. A project has associated users and clusters, and users associated with the project can run jobs on those complexes and charge the project account.

Reconciling Jobs

Prepaid mode only. After a job runs, Budgets reconciles charges for the job: it debits escrow for the amount consumed by the job and returns any excess to the job owner, or if the job consumed more than requested it debits more from the job owner's account.

Roles

Roles define available actions and access to features in Budgets. Roles can be *admin*, *investor*, *manager*, *teller*, and *user*.

Service Unit

A standard service unit represents a currency, which can be dollars, CPU hours, GPU hours, etc; see section 1.7.2.1, "Standard Service Units", on page 19.

A dynamic service unit lets you set a quota on an externally-managed resource such as storage; see section 1.7.2.2, "Dynamic Service Units", on page 19.

Standard Service Units

Currency representing compute resources, budget resources, time resources, or a combination. Defined by the Budgets administrator; can be specific to the needs of the client. Examples: CPU hours, GPU hours, dollars.

Dynamic Service Units

Mechanism for placing a quota on an external compute resource such as storage. If a quota is exceeded, jobs that depend on that dynamic service unit do not start.

Transactions

An action that affects a credit balance, such as depositing or refunding service units to an account, or withdrawing service units from an account.

User, User Account

We use these terms to mean two different things:

- Budgets entity representing an individual user and their associated account, including its credit balance. This user is typically a job submitter with the *user* role, although an individual user can have any role. Each user account is funded by at least one group manager. See section 1.6.3, "User, User Account", on page 16.
- Username, password, etc. for administrator, database user, teller, or job submitter. See section 2.5.1, "Create Required User Accounts", on page 32.

Worker

Process that handles transactions for Budgets. This process is run by the web server.

1.4 Roles

Roles define available actions in and access to the features of Budgets. Except for the *teller* role, roles are hierarchical; each role includes the capabilities of the roles below it in the hierarchy. For example, if a user is defined as an *investor*, they can be added later to a group as a manager. A user can have only one role at a time, although that role may have the privileges of lower roles. Roles are case-sensitive and are lowercase. The *teller* role is a special-purpose role for processing transactions, and its capabilities are shared only with the *admin* role.

In hierarchical order, with the most powerful and inclusive role first:

admin

Budgets administrator. Configures Budgets; adds users, projects, groups, clusters, sets roles, defines periods, gives refunds, etc. Can modify any element in Budgets. Can transfer service units from any entity to any entity.

When you install Budgets, you specify a username for the Budgets administrator. This account automatically gets assigned the *admin* role. This username is typically *pbsadmin*.

Not automatically associated with specific projects or groups.

The *admin* role includes the capabilities of the *investor*, *manager*, *teller*, and *user* roles.

investor

A user who is associated with a group and is responsible for investing service units in the associated group account. Can also withdraw service units from the group account. An investor can be associated with one or more groups.

Created by Budgets administrator.

The *investor* role includes the capabilities of the *manager* and *user* roles.

manager

A user who is associated with a group and is responsible for depositing service units from the group account to associated user and project accounts. Can also withdraw service units from these user and project accounts, putting them back into the group account. Can be associated with multiple groups.

Created by Budgets administrator.

The *manager* role includes the capabilities of the *user* role.

teller

A user who performs all acquire and reconcile transactions on behalf of projects and users. When the Budgets hook performs these actions, it uses the *teller* role and username amteller.

The teller has full permissions for transactions and can read all projects, accounts, groups, etc.

Not associated with groups or projects.

The *teller* role is a special-purpose role for processing transactions, and its capabilities are shared only with the *admin* role.

Created by Budgets administrator.

The *teller* role includes the capabilities of the *user* role.

user

PBS job submitters who have an individual account and/or are associated with a project. A job submitter with an individual account can charge jobs to their own account. A job submitter who is associated with a project can charge jobs to the project.

Created by Budgets administrator.

Operations:

- When you create any user, you must assign a role to that user; see section 4.2.1.2, “Adding a User”, on page 80.
- To see all roles that have been created, list them; see section 4.2.2.9, “Listing Roles”, on page 89.
- To change a user's role, use `amgr update user`; see section 4.2.3.2, “Updating Users”, on page 93.

1.5 Investing and Consuming Service Units

Investing and consuming service units is required only in prepaid mode.

1.5.1 Investing in Groups (Cost Centers)

Groups in Budgets represent organizational entities such as departments or businesses. For example, an organization might have multiple departments including engineering, systems, and software. The CFO, who can be represented in Budgets as an investor, deposits service units to a department's group account. An investor can deposit to multiple groups, and a group can have multiple investors.

The amount each investor dispenses to a group is tracked. An investor can withdraw funds from a group, but cannot withdraw more than the amount they deposited to that group.

The group budget pool does not have any defined period. The amount in the budget pool is available for an infinite amount of time.

Operations:

- Investor invests in a group via `amgr deposit group`; see section 4.3.1.3, "Depositing Service Units to Group", on page 121.
- Investor withdraws from a group via `amgr withdraw group`; see section 4.3.3.3, "Withdrawing Service Units from Group", on page 124.
- Administrator transfers between groups via `amgr transfer group`; see section 4.3.8.5, "Transferring Service Units for Investors and Group", on page 134.

Figure 1-1 shows the basic path for investment/allocation of credit. Each arrow indicates a path for investment/allocation. A group investor puts credit in a group account, and a group manager allocates group credit to users and projects.

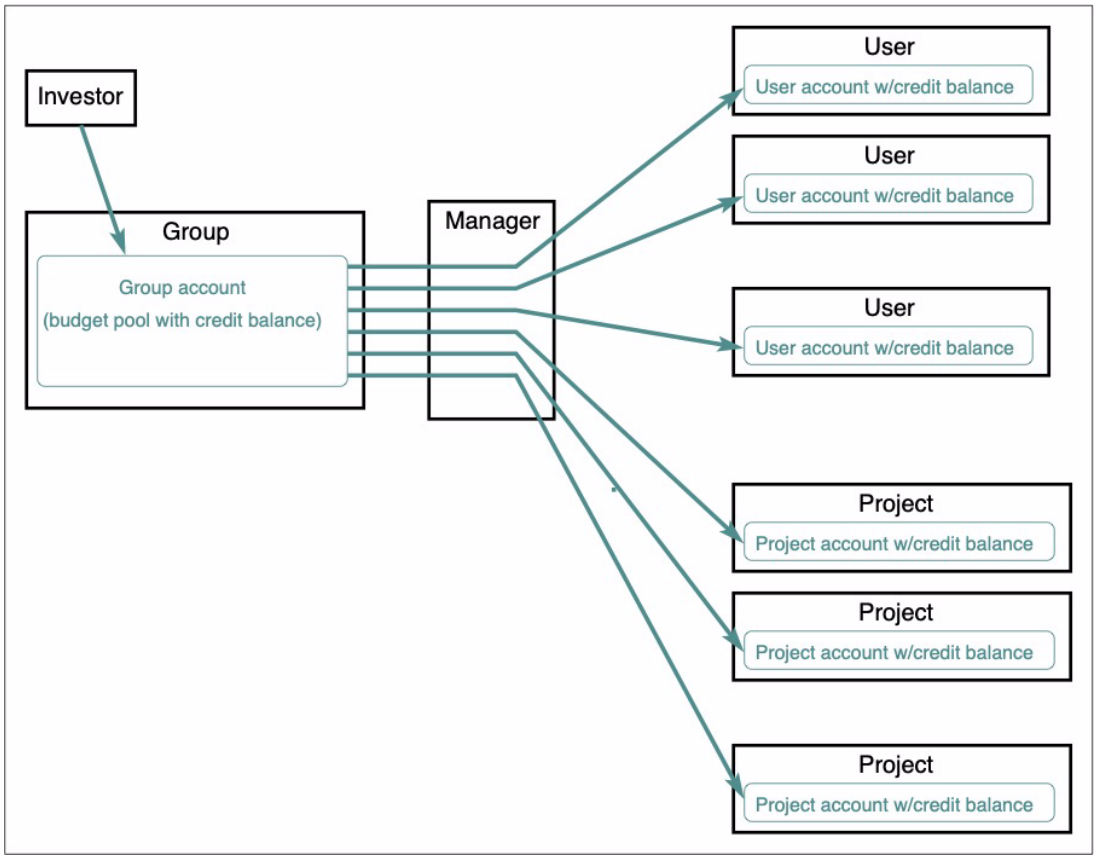

Figure 1-1: Basic investment path

1.5.2 Investing in Users and Projects

Once the group has been been allocated service units, group managers can use that pool to fund projects and users. Each allocation to a user or project is for a specific period of time. For example, the engineering group managers can allocate funds to the design project for Quarter1 and to the testing project for Quarter2 and Quarter3.

A manager can use up to the entire pool on one user or project.

Each group manager can be linked to multiple groups, and each group can have multiple managers. Each group can fund multiple users and projects, and each user or project can have multiple groups funding it.

If necessary, a group manager can also withdraw funds from projects and users, but only up to the amount they deposited.

Figure 1-2 shows how credit can be allocated through multiple paths. Each arrow shows a potential investment path. An investor can be associated with multiple groups, a group can receive credit from multiple investors, a manager can be associated with multiple groups, a group can have multiple managers, and a user or project can be allocated credit from multiple groups and by multiple managers.

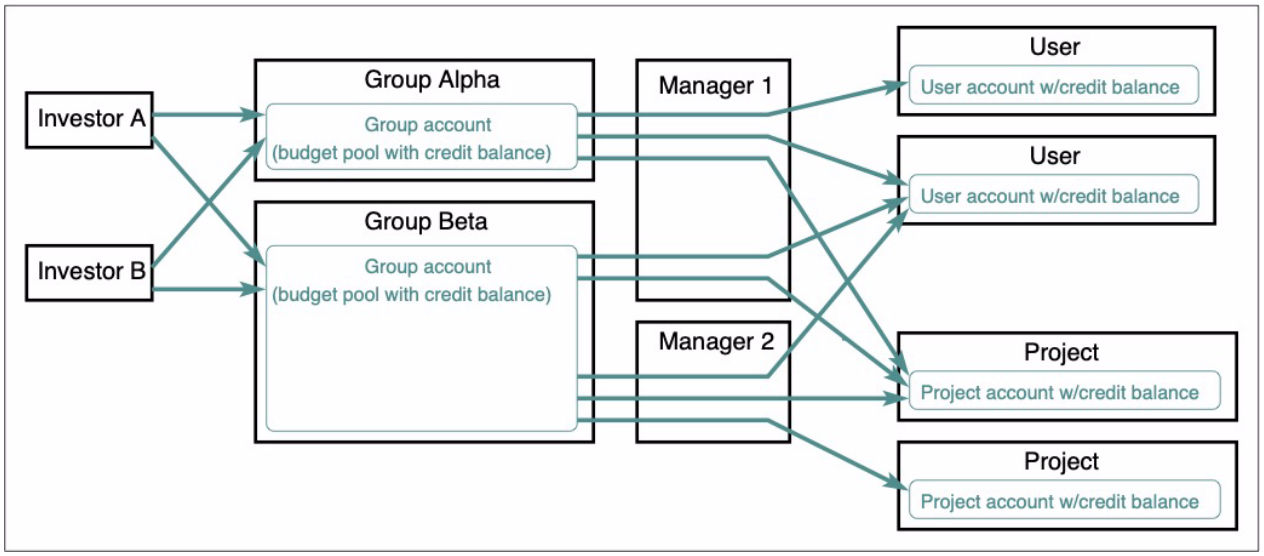

Figure 1-2: Multiple investment paths

1.5.3 Charging Jobs to User or Project Account

The Budgets hook monitors each job submission, and when the job submitter specifies a project via `qsub -P <project name>`, Budgets charges the job to that project. If the job submitter does not specify a project, Budgets charges the job to the job submitter's own account.

1.5.4 Job and Credit Lifecycle

1.5.4.1 Job and Credit Lifecycle in Postpaid Mode

When a job runs, it can consume multiple kinds of service units, for example both CPU hours and GPU hours.

1. User submits a job, charging it either to the user's account or a project account
2. Budgets validates membership of the job owner (a user or project)
3. Job is queued at PBS server
4. Job runs at execution host(s)
5. When the job finishes, Budgets debits the amount of credit that was consumed by the job
6. After the job finishes, the administrator can optionally refund credit for the job

1.5.4.2 Job and Credit Lifecycle in Prepaid Mode

When a job runs, it can consume multiple kinds of service units, for example both CPU hours and GPU hours.

1. User submits a job, charging it either to the user's account or a project account
2. Budgets validates membership of the job owner (a user or project)
3. Optionally, Budgets validates credit of the job owner (a user or project)
4. Job is queued at PBS server
5. Before running the job:
   a. Budgets checks balance of job owner's account
   b. Budgets acquires service units from job owner and puts them in escrow
6. Job runs at execution host(s)
7. When the job finishes, Budgets reconciles the job: it debits the amount of credit that was consumed by the job and returns any excess to the user or project, or if the job consumed more than requested it debits more from the job owner's account
8. After the job finishes, the administrator can optionally refund credit for the job

1.5.5 Reconciling Jobs

For prepaid mode only. When a job finishes, Budgets reconciles the job by debiting the amount of credit used by the job, and returning the excess to the job owner's account, or if the job consumed more than requested it debits more from the job owner's account. However, in rare cases a job cannot be reconciled when the job fails. Budgets will try to reconcile a job up to 3 times; if it is not successful, it marks the job as not reconciled.

To see all unreconciled jobs that have had *count* or more attempts to reconcile:

amgr report transaction -i <job or transaction ID> -N <count>

For example, `amgr report transaction -N 2` displays all non-reconciled jobs with *count* >=2.

See section 4.2.5.5, “Getting Job and Transaction Reports”, on page 115.

You have to manually reconcile jobs with 3 failed attempts.

To reconcile a job that is part of a project:

amgr reconcile project -n <project name> -c <cluster> -f <formula file> -s <service unit name> <service unit amount> [-D <transaction date>] -u <job owner username> -i <transaction ID> -d <duration> [-C <comment>]

To reconcile a job that is not part of a project:

amgr reconcile user -n <username> -c <cluster> -f <formula file> -s <service unit name> <service unit amount> [-D <transaction date>] -u <job owner username> -i <transaction ID> -d <duration> [-C <comment>]

See section 4.3.6, “Reconciling Service Units”, on page 130.

1.5.6 Refunding Users and Projects

For postpaid and prepaid modes. The administrator can refund the user or project that funded a job for some or all of the service units charged for the job. You can choose to provide a refund for situations such as when a job fails or runs multiple times, for reasons which cannot be attributed to the job owner. You can provide refunds to active and inactive projects and users. You can provide multiple refunds for the same job, but the total refund cannot exceed the amount consumed by the job.

Budgets knows who paid for the job, so you do not have to specify where the refund goes. The refund amount is calculated by multiplying the specified percentage by the total consumed amount. Total consumed amount is the sum of all transaction amounts of all transactions for a job. Refunds are strictly per job.

You must be *admin* to provide a refund.

When a job is refunded, the comment in the report is always prefixed with "refund:".

See section 4.3.7, “Refunding Service Units”, on page 132.

1.5.7 Retrieving Abandoned Service Units

If service units go unclaimed and become unusable, the *admin* role can transfer them so that they become usable. You can transfer from any period, group, user, or project, to any other period, group, user, or project. You can transfer between investors in the same group or different groups. A transfer gets its own transaction ID.

Service units may become unusable when the following happen:

- An investor is unlinked from a group, leaving funds with the group
- A group is unlinked from a project, leaving funds with the project
- A period expires and leaves service units unused in a user or project account

See section 4.3.8, “Transferring Service Units”, on page 133.

You must be *admin* to run this command.

1.6 Accounts in Budgets

1.6.1 Group, Group Account

A group, also called a group account, is a type of account that represents an organizational structure such as a department, a business unit, etc. A group has the following:

- Name
- Credit balance
- One or more investors
- One or more managers
- Is active or inactive

Group managers provide the funding for users and projects to run jobs by depositing service units to those accounts. Group managers can also withdraw service units from associated job and project accounts and return the service units to the group account. All funding for users and projects comes from groups. The group credit balance is in standard service units; see Service Units.

Group managers can also set a quota on an externally-managed resource such as storage by setting a limit for the dynamic service unit representing that resource. A dynamic service unit limit is per user, project, and period, so you can set a different limit for each user and project for each period. Budgets checks usage by the job owner against this quota before running any job. See section 1.7.2.2, "Dynamic Service Units", on page 19.

Groups do not:

- Directly run jobs
- Have associated time periods
- Have associated dynamic service units

Operations:

- Administrator adds group via `amgr add group`; see section 4.2.1.4, "Adding a Group", on page 82
- Administrator updates group via `amgr update group`; see section 4.2.3.4, "Updating Groups", on page 95
- User lists group via `amgr ls group`; see section 4.2.2.4, "Listing Groups", on page 86
- Administrator removes group via `amgr rm group`; see section 4.2.4.4, "Removing a Group", on page 102. Note that if a group has any associated current or past transactions, removing it results only in making it inactive.
- Group manager deposits service units to users and projects via `amgr deposit`; see section 4.3.1, "Depositing Service Units", on page 119
- Group manager withdraws service units from users and projects via `amgr withdraw`; see section 4.3.3, "Withdrawing Service Units", on page 123
- Manager checks credit balance of group via `amgr checkbalance group`; see section 4.3.2.6, "Checking Service Unit Balance for Group", on page 122
- Group manager transfers service units to and from users and projects via `amgr transfer`; see section 4.3.8, "Transferring Service Units", on page 133
- Manager gets reports on groups via `amgr report group`; see section 4.2.5.4, "Getting Group Reports", on page 112
- Investor invests in a group via `amgr deposit group`; see section 4.3.1.3, "Depositing Service Units to Group", on page 121.
- Investor withdraws from a group via `amgr withdraw group`; see section 4.3.3.3, "Withdrawing Service Units from Group", on page 124.
- Administrator transfers between groups via `amgr transfer group`; see section 4.3.8.5, "Transferring Service Units for Investors and Group", on page 134.

The difference between being active and inactive is that an active group can participate in transactions, but an inactive group cannot.

1.6.2 Project, Project Account

A project account is designed to represent a project such as a workflow. It has the following:

- Name
- Credit balance which it can use to run jobs
- One or more associated groups
- One or more associated users
- One or more associated clusters representing PBS complexes
- Accounting policy; see section 1.7.4, “Accounting Policy”, on page 23
- Optional independent start date
- Optional independent end date
- Optional metadata
- State: active or inactive

A project acquires credit when a group manager deposits group credit to the project account. A project spends credit when a user associated with the project runs a job and charges the job to the project account. A job can be charged to a project account only when it is run by an associated user on an associated complex. Any user associated with the project can charge a job to the project account. A project can use multiple clusters.

When a group manager deposits group credit to a project account, that allocation is for a specific period and in a specific currency (service unit). Currency is usually defined as resource usage, such as CPU hours or GPU hours, but can be in dollars or other monetary units.

Operations:

- Administrator adds project via `amgr add project`; see section 4.2.1.3, "Adding a Project", on page 81
- Administrator updates project via `amgr update project`; see section 4.2.3.3, "Updating Projects", on page 93
- Project member lists project via `amgr ls project`; see section 4.2.2.3, "Listing Projects", on page 86
- Administrator removes project via `amgr rm project`; see section 4.2.4.3, "Removing a Project", on page 102. Note that if a project has any associated current or past jobs or transactions, removing it results only in making it inactive.
- Group manager deposits service units to project via `amgr deposit project`; see section 4.3.1.2, "Depositing Service Units to Project", on page 120
- Group manager withdraws service units from project via `amgr withdraw project`; see section 4.3.3.2, "Withdrawing Service Units from Project", on page 123
- Project member, investor, or manager checks credit balance of project via `amgr checkbalance project`; see section 4.3.2.5, "Checking Service Unit Balance for Project", on page 122
- Group manager transfers service units to and from projects via `amgr transfer project`; see section 4.3.8.4, "Transferring Service Units for Project", on page 134
- Administrator or teller reconciles service units for project via `amgr reconcile project`; see section 4.3.6.3, "Reconciling Service Units for Project", on page 131
- Group manager applies limits to dynamic service units for project via `amgr limit project`; see section 4.2.6, "Applying Limits to Dynamic Service Units", on page 116
- Administrator or teller acquires service units for project via `amgr acquire project`; see section 4.3.5.4, "Acquiring Service Units for Project", on page 129
- Project member, investor, or manager prechecks service unit balance for project via `amgr precheck project`; see section 4.3.4.1, "Prechecking a User or Project", on page 125
- Project member, investor, or manager gets reports on projects via `amgr report project`; see section 4.2.5.3, "Getting Project Reports", on page 106

The difference between being active and inactive is that an active project can run jobs and participate in transactions, but an inactive project cannot.

Project start and end times are not periods and are independent of periods.

When you create a project, you must assign an accounting policy and at least one cluster.

1.6.2.1 Project Attributes

Projects have a metadata attribute, consisting of comma-separated key-value pairs, where the keys are undefined. The administrator can set, update, or remove metadata when creating or updating a project.

Example 1-1: Add metadata to project:

```
amgr update project -n project1 -m + Owner:"Owner1"
```

Example 1-2: See metadata by getting a project report in prepaid mode:

```
amgr report project -n project1
--------------------------------------------------------------------------------
name     | period   | serviceunit | opening_balance | ... | metadata            |
--------------------------------------------------------------------------------
project1 | 2022.feb | cpu_hrs     | 0.0             | ... | {'Owner': 'Owner1'} |
```

Example 1-3: See metadata by listing project:

```
amgr ls project -n project1 -l
project1
    account = project1
    metadata = {'Owner': 'Owner1'}
...
```

Example 1-4: Remove metadata:

```
amgr update project -n project1 -m - Owner
```

Example 1-5: Verify by listing project:

```
amgr ls project -n project1 -l
project1
    account = project1
    metadata = {}
...
```

1.6.3 User, User Account

Entity representing an individual user and their associated account, including its credit balance. This user is typically a job submitter with the *user* role, although an individual user can have any role. A user has the following:

- Name, which is the username
- Credit balance
- One or more associated groups
- One or more associated clusters representing PBS complexes
- Optionally, one or more projects with which the user is associated
- Role; see section 1.4, “Roles”, on page 7
- Accounting policy; see section 1.7.4, “Accounting Policy”, on page 23
- Is active or inactive

A user acquires credit when a group manager deposits group credit to the user account. A user spends credit when that user runs a job and charges the job to their account. A job can be charged to a user account only when it is run by that user on a complex associated with that user. A user can be assigned to zero or more projects. When a user runs a job, they can charge the job to an associated project account, or to their own account.

When a group manager deposits group credit to a user account, that allocation is for a specific period and in a specific currency (service unit). Currency is usually defined as resource usage, such as CPU hours or GPU hours, but can be in dollars or other monetary units.

A user with any role can have an individual user account.

Operations:

- Administrator adds user via `amgr add user`; see section 4.2.1.2, "Adding a User", on page 80
- Administrator updates user via `amgr update user`; see section 4.2.3.2, "Updating Users", on page 93
- Job submitter lists self, or manager lists user user via `amgr ls user`; see section 4.2.2.2, "Listing Users", on page 85
- Administrator removes user via `amgr rm user`; see section 4.2.4.2, "Removing a User", on page 101. Note that if a user has any associated current or past jobs or transactions, removing it results only in making it inactive.
- Group manager deposits service units to user via `amgr deposit user`; see section 4.3.1.1, "Deposit Service Units to User", on page 119
- Group manager withdraws service units from user via `amgr withdraw user`; see section 4.3.3.1, "Withdrawing Service Units from User", on page 123
- Job submitter checks own credit balance, or manager checks credit balance of user via `amgr checkbalance user`; see section 4.3.2.4, "Checking Service Unit Balance for User", on page 122
- Administrator transfers service units to and from users via `amgr transfer user`; see section 4.3.8.3, "Transferring Service Units for User", on page 133
- Group manager applies limits to dynamic service units for user via `amgr limit user`; see section 4.2.6, "Applying Limits to Dynamic Service Units", on page 116
- Administrator or teller acquires service units for user via `amgr acquire user`; see section 4.3.5.3, "Acquiring Service Units for User", on page 129
- Administrator or teller reconciles service units for user via `amgr reconcile user`; see section 4.3.6.2, "Reconciling Service Units for User", on page 130
- Job submitter prechecks own service unit balance, or manager prechecks service unit balance for user via `amgr precheck user`; see section 4.3.4.1, "Prechecking a User or Project", on page 125
- Job submitter prechecks whether own service unit balance is sufficient for specific jobs, or manager prechecks service unit balance for user jobs, via `amgr precheck jobs`; see section 4.3.4.2, "Prechecking Jobs", on page 126
- Job submitter gets report on self, or manager gets reports on user via `amgr report user`; see section 4.2.5.2, "Getting User Reports", on page 104

The difference between being active and inactive is that an active user can run jobs and participate in transactions, but an inactive user cannot.

1.6.3.1 Requirements for Adding Job Submitters

When you create a user, you must assign a role, an accounting policy, and at least one cluster.

Each user you add to Budgets should already have an entry in the password file, with a password set, and a home directory on the Linux system where Budgets is installed.

When you add a user who will run jobs, that user must already be able to run jobs in a PBS complex.

1.7 Accounting Tools

1.7.1 Periods, Allocation Periods, Billing Periods

A period, also called a billing period or an allocation period, is a defined period of time with fixed start and end dates.

When a group manager deposits service units to a project or user account, that allocation is deposited for a specific period. The allocation is available to the project or user for that period only, expires at the end of the period, and is reported against that period.

Group accounts do not have associated periods.

The Budgets administrator creates all periods. You can create a hierarchy of billing periods where the parent period encompasses the child periods. For example the parent period can be Year, and the child periods can be Quarter1, Quarter2, etc. There is no limit to the depth of the hierarchy.

Operations:

- Administrator adds period via `amgr add period`; see section 4.2.1.6, “Adding a Period”, on page 83
- Administrator updates period via `amgr update period`; see section 4.2.3.6, “Updating a Period”, on page 96. Note that if a period has any associated jobs or transactions, you cannot update it.
- Any user lists any period via `amgr ls period`; see section 4.2.2.6, “Listing Periods”, on page 88
- Administrator removes period via `amgr rm period`; see section 4.2.4.6, “Removing a Period”, on page 103. Note that if a period has any associated current or past jobs or transactions, you cannot remove it.

1.7.1.1 Caveats for Creating Periods

- Make sure that periods at the same level do not overlap. For example, if Quarter1 ends March 31st, make sure that Quarter2 does not begin sooner than April 1st.
- If you want to create periods with a parent-child relationship, you must create the parent period first. You cannot add a parent to an existing child. For example, if you want Year as the parent and Quarter1, Quarter2, etc., as children, create Year first.
- If you create child periods, make sure that they fit within the parent period.
- Make sure that your period hierarchy is finalized BEFORE doing any transactions or running any jobs; you cannot update or remove periods once transactions have been performed or jobs have started.

1.7.2 Service Units

Budgets has two types of service units:

- You use *standard service units* to track and bill for resource usage, such as dollars, CPU hours, or GPU hours; this type is *SU_STANDARD*
- You use *dynamic service units* to set quotas on externally-managed resources such as storage; this type is *SU_DYNAMIC*

You can define as many service units as you need, and you can define each one to be whatever you need. You can define and use different service units for billing at each PBS complex. A job, project, or user can consume multiple service units. The default type is *SU_STANDARD*.

Operations:

- Administrator adds service unit via `amgr add serviceunit`; see section 4.2.1.7, "Adding a Service Unit", on page 84
- Administrator updates service unit via `amgr update serviceunit`; see section 4.2.3.7, "Updating a Service Unit", on page 97. You can update the type of a service unit only when it has no associated transactions or value updates. Use this command to set a service unit active or inactive.
- Any user lists service unit via `amgr ls serviceunit`; see section 4.2.2.7, "Listing Service Units", on page 88
- Administrator removes service unit via `amgr rm serviceunit`; see section 4.2.4.7, "Removing a Service Unit", on page 103. Note that if a service unit has any associated current or past transactions, removing it results only in making it inactive.
- Administrator uses `cron` script to update dynamic service unit usage `via amgr update dynamicvalues`; see section 4.2.3.9, "Updating Dynamic Service Unit Usage", on page 98.
- Administrator sets a limit on the service unit via `amgr limit {user | project}`; see section 4.2.6, "Applying Limits to Dynamic Service Units", on page 116
- Administrator defines each service unit in the billing formulas; see section 3.2.3, "Define Billing Formulas", on page 62

The difference between being active and inactive is that an active service unit can be used for transactions or for quota checks, but an inactive one cannot; it cannot be invested, transferred, consumed, etc.

1.7.2.1 Standard Service Units

A standard service unit can be a monetary unit such as dollars, or it can represent an internally-managed resource such as CPU hours or GPU hours. Standard service units can be treated like a currency.

The Budgets hook runs at the PBS complex where a job runs and tracks standard service unit usage by the job. Budgets debits the account of the job owner for the usage by the job. When you manage a PBS complex via Budgets, each PBS job can run only when the job can be charged to a project or user account that has sufficient standard service units.

1.7.2.1.i Adding and Removing Standard Service Units

You can create separate standard service units for each cluster.

To create a standard service unit and add it to Budgets:

1. Define the service unit in a billing formula; see section 3.2.3, "Define Billing Formulas", on page 62
2. Add the service unit to Budgets via amgr `add serviceunit -n <name of new service unit>`; see section 4.2.1.7, "Adding a Service Unit", on page 84

To remove a standard service unit:

1. Remove the service unit from all formulas, otherwise jobs will not run
2. Remove the service unit from Budgets via `amgr rm serviceunit -n <service unit name>`; see section 4.2.4.7, "Removing a Service Unit", on page 103

1.7.2.2 Dynamic Service Units

A dynamic service unit tracks an external resource such as storage. You use a dynamic service unit by setting a limit on it to establish a quota. You can set separate limits on a dynamic service unit for each user and project, and for each user or project, you can specify a different limit for each period, via `amgr limit {user | project}`; see section 4.2.6, "Applying Limits to Dynamic Service Units", on page 116. To set a limit on a dynamic service unit for a user or project, you must be the group manager for the group that provides standard service units for that user or project.

Budgets checks whether a job owner has hit a quota before starting each job. If a job owner hits a quota, they cannot start any more jobs until either the limit is raised or usage goes down.

1.7.2.2.i Caveats for Dynamic Service Units

If a dynamic service unit has no limit set on it, the limit is zero. If there are active dynamic service units, all jobs are checked against those quotas, and a zero quota will stop any job from running. Make sure that you don't unintentionally stop non-target users or projects from running jobs:

- Make sure you set the quota for all users and projects
- When you specify the period, make sure you either:
  - Set the desired quota at the top level of the period hierarchy
  - Set a very high quota at the top level of the period hierarchy, and a more restrictive quota for the period you need to control

1.7.2.2.ii Attributes for Dynamic Service Units

The data_lifetime Budgets configuration attribute specifies the maximum time period between updates to dynamic service units. The default value is 3600 seconds. See section 3.3, "Setting Budgets Configuration Attributes", on page 73.

1.7.2.2.iii Adding and Removing Dynamic Service Units

To create and use a dynamic service unit, you add it to Budgets, set a limit, and keep its value updated:

1. Add the service unit to Budgets via amgr `add serviceunit -n <name of new service unit>`; see section 4.2.1.7, "Adding a Service Unit", on page 84
2. Set a limit on the service unit via `amgr limit {user | project}`; see section 4.2.6, "Applying Limits to Dynamic Service Units", on page 116
3. Periodically update the value of the service unit by having a `cron` script call `amgr update dynamicvalues`; see section 4.2.3.9, "Updating Dynamic Service Unit Usage", on page 98. The script should update the value at intervals that are smaller than the limit set in the data_lifetime attribute; the default value is 3600 seconds. See section 3.3, "Setting Budgets Configuration Attributes", on page 73

To remove a dynamic service unit from Budgets, use `amgr rm serviceunit -n <service unit name>`; see section 4.2.4.7, "Removing a Service Unit", on page 103

1.7.2.2.iv Checking Quotas (Limits on Dynamic Service Units)

There may be quotas set on externally-managed resources such as storage. A quota is a limit on a dynamic service unit. To see quotas, list all service units:

```
amgr ls serviceunit
```

See section 4.2.2.7, "Listing Service Units", on page 88.

1.7.2.3 Examples of Storage Quotas via Dynamic Service Units

Example 1-6: Setting user and project quotas:

Set user quota:

```
amgr limit user -n user1 -s storage 12.0 -p 2022
```

Set project quota:

```
amgr limit project -n project1 -s storage 25.0 -p 2022
```

Example 1-7: Setting consumption by user and project. This call is typically made via a `cron` job, and you would want to make sure you set this more often than the limit in the data_lifetime attribute:

Set consumption for user1:

```
amgr update dynamicvalues -v '{"storage": {"user1": {"total":8}}}'
```

Set consumption for project1:

```
amgr update dynamicvalues -v '{"storage": {"project1": {"total":30}}}'
```

Example 1-8: Reporting storage usage:

Report user storage data:

```
amgr report user -n user1 -t SU_DYNAMIC
--------------------------------------------------------------------------------
name     | serviceunit  | period    | limit   | last_reported_time  | total_consumed
--------------------------------------------------------------------------------
user1    | storage      | 2022.feb  | 12.0    | 2022-02-11 18:58... | 8.0
```

Report project storage data:

```
amgr report project -n project1 -t SU_DYNAMIC
--------------------------------------------------------------------------------
name     | serviceunit  | period    | limit   | last_reported_time  | total_consumed
--------------------------------------------------------------------------------
project1 | storage      | 2022.feb  | 25.0    | 2022-02-11 18:58... | 30.0
```

Example 1-9: Queued job for project1 won't run. Why? Because it is over quota as shown in the report above.

```
qstat 3269
Job id                  Name             User              Time Use S Queue
----------------------  ---------------- ----------------  -------- - -----
3269.testbed            workq_test       user1                    0 Q workq
qstat -f 3269 | grep comment
comment = Not Running: PBS Error: Budgets: Consumption has reached the
limit for a dynamic service unit storage
```

1.7.2.4 Rules for Using Service Units

- You can change the type of a service unit, but there are restrictions:
  - You can change standard to dynamic only when no transactions have taken place for that service unit
  - You can change dynamic to standard only when no updates have been made to the usage of that service unit
- In the billing formula file, you can use only standard service units.
- All active dynamic service units must have a limit set in order for jobs to run
- When you create a new child period, it inherits its limits for any dynamic service units from its parent
- If you apply a limit directly to a dynamic service unit for a period, that overrides any inherited limit
- If you apply a limit to a period, all child periods that are not directly limited inherit the limit; similarly, limits on child periods are inherited by children of those child periods, when no direct limits have been set
- Only administrators can update dynamicvalues
- The maximum amount of each service unit an account can hold is 999999999999.99.

1.7.3 Transactions

A transaction is an operation on a service unit, such as a deposit or transfer. We say a transaction is an element in Budgets. Budgets also uses checks on account balances; these are not transactions, but they are also elements in Budgets.

Table 1-1: Transactions and Checks

Name	Operation	Format	When	Purpose
Deposit	Deposit service units to user, project, or group account Depositing Service Units	Unique float	Any time	Investor funds group. Group manager funds user or project from group account.
Withdraw	Withdraw service units from user, project, or group account Withdrawing Service Units	Unique float	Any time	Investor withdraws funds from group. Group manager withdraws service units from user or project and returns them to group account.
Transfer	Move service units from one investor or user, project, or group account to another Transferring Service Units	Unique float	Any time	Administrator transfers service units between investors, groups, periods, projects, and users. Useful when period expires leaving unused funds; these funds can be transferred where needed.
Refund	Refund service units from group account to user or project account Refunding Service Units	Job ID plus date, time stamp, and operation (shown in report)	Any time	Administrator refunds job owner for costs out of job owner's control, for example re-run caused by node failure. Refunds are strictly per-job.
Acquire	Service units from job owner's account are put in escrow before running the job Acquiring Service Units	Job ID plus date, time stamp, and operation (shown in report)	Before job runs	Hook moves credit from job owner's account to escrow. Can be used as a debug tool by administrator.
Reconcile	Service units consumed by job are removed from escrow. Returns unused service units in escrow, or if job consumed more than requested, debits more from job owner account Reconciling Service Units	Job ID plus date, time stamp, and operation (shown in report)	After job runs	Hook reconciles accounts after job ends: debits escrow for amount consumed by job and returns unused credit to job owner, or if job consumed more than requested, debits more from the job owner's account. Can be used as a debug tool by administrator.
Precheck	Check job owner account for sufficient service units; disallow queueing job if insufficient Prechecking Service Unit Balance	Not a transaction; no ID	Before queueing job	Hook can optionally disallow queueing of jobs owned by accounts with insufficient service units. Can be used as a debug tool by administrator.
Checkbalance	Check job owner account for sufficient service units; do not run job if insufficient Checking Service Unit Balance	Not a transaction; no ID	Before job runs	Hook checks job owner credit balance before allowing job to run.

You can get reports on transactions; see section 4.2.5.5, “Getting Job and Transaction Reports”, on page 115.

1.7.3.1 Transaction IDs

Every transaction has a transaction ID.

- Transactions associated with jobs, such as acquiring service units to run the job, consist of the job ID, a date, a timestamp, and an operation, shown in the report. For example:
  ```
  1235.myserver  2022-10-06  17:15:23.760451  ...  acquired  ...
  ```
- Other transactions have a unique floating-point number for their transaction ID. This format has 10 digits before the point and 7 after the point, for example:
  ```
  0123456789.1234567
  ```

1.7.4 Accounting Policy

You must specify an accounting policy for each user and project when you add them to Budgets. The policy determines how the entity is charged for its jobs. You can set the accounting policy when you add or update the entity via the `-A <accounting policy>` option to the `amgr add` or `amgr update` commands. There is no default policy. The accounting policy is case-sensitive, and it is lowercase. You have the following options:

begin_period
: The user or project account is charged when the job begins.

end_period
: The user or project account is charged when the job ends.

proportionate
: The user or project account is charged during all periods when the job runs, and each period is charged in proportion to the usage during that period.

1.7.5 Clusters

A cluster is a data structure representing a PBS complex. Each cluster is named for its PBS server; the server name is the value of the PBS_SERVER parameter in the `/etc/pbs.conf` file. Cluster names (and therefore PBS server names) must be unique. The cluster formulas must be the same as the formulas at the complex, otherwise jobs won't run. If you log into a PBS complex and change a formula there, update the cluster data structure at the Budgets host via `amgr update cluster`.

When you run `amgr add cluster` or `amgr update cluster`, you are also updating the database with the formulas for the cluster.

A cluster has the following:

- Name; this must be the name of the PBS server for the PBS complex, found in the PBS_SERVER parameter in the `/etc/pbs.conf` file
- Billing formulas; see section 3.2.3, “Define Billing Formulas”, on page 62
- Is active or inactive

In order for a user or project to be able to run a job at a PBS complex, its representative cluster must be associated with the user or project.

Cluster operations:

- Administrator adds a cluster to Budgets via `amgr add cluster`; see section 4.2.1.5, “Adding a Cluster”, on page 83
- Administrator updates a cluster via `amgr update cluster`; see section 4.2.3.5, “Updating Clusters”, on page 96
- Any user lists a cluster via `amgr ls cluster`; see section 4.2.2.5, “Listing Clusters”, on page 87
- Administrator removes a cluster via `amgr rm cluster`; see section 4.2.4.5, “Removing a Cluster”, on page 102. If the cluster has any associated jobs or transactions, the remove operation only makes the cluster inactive.

The difference between an active and an inactive cluster is that an active cluster can run jobs and participate in transactions, but an inactive cluster cannot. Otherwise they are the same.

Figure 1-3 shows the relationship between a cluster and its associated PBS complex.

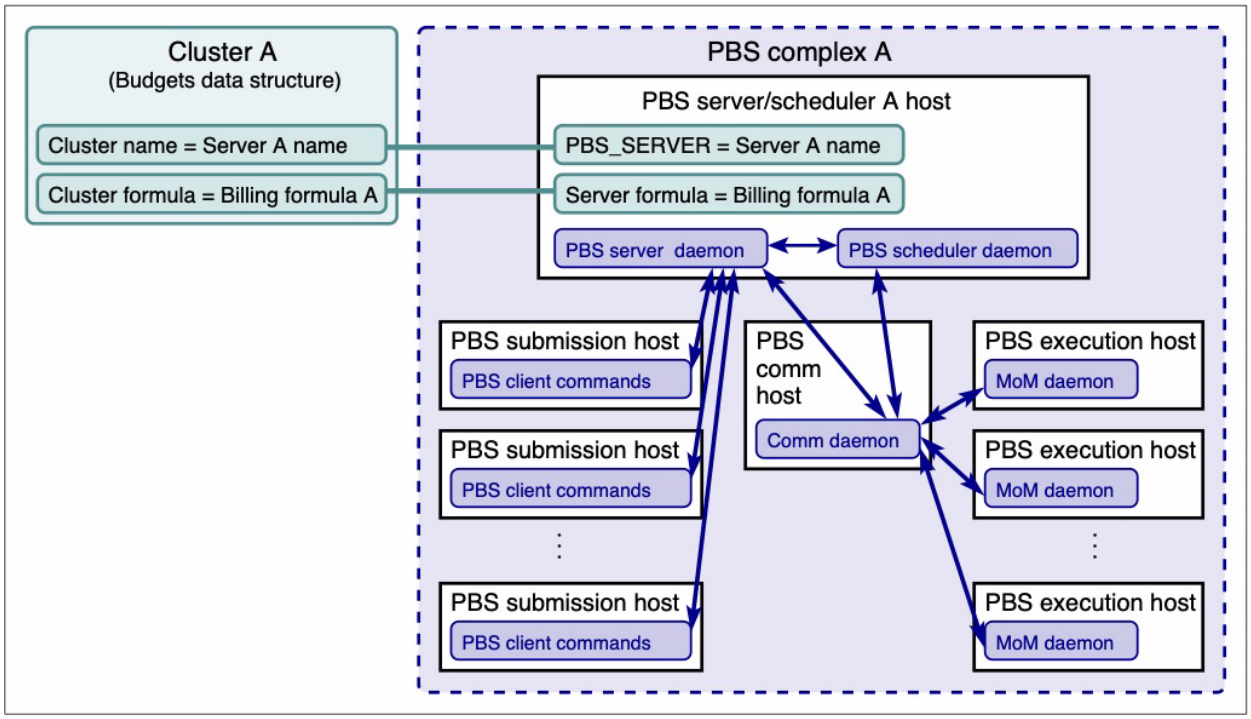

Figure 1-3: Relationship between cluster and PBS complex

1.8 Summary of Setting Budgets Up for Postpaid or Prepaid Mode

1.8.1 Summary of Using Postpaid Mode

To set Budgets up to use postpaid mode, you need to create the relevant clusters, an active period, the desired service unit, and accounts for any job submitters. If you want to use projects, you need to create any relevant project accounts. You also need to make sure that each job submitter is a member of the relevant cluster.

If job submitters want to pay their balance off early, you need to create a group for the job submitters, a manager for the group, an investor for the group, an investment to the group, and a grant from the group to each job submitter.

1.8.2 Summary of Using Prepaid Mode

To set Budgets up to use prepaid mode, you need to create the relevant clusters, an active period, the desired service unit, and accounts for any job submitters. You also need to create a group for the job submitters, a manager for the group, an investor for the group, an investment to the group, and a grant from the group to each job submitter. You also need to make sure that each job submitter is a member of the relevant cluster.

If you want to use projects, you need to create any relevant project accounts, and add the submitters as members of the projects.

1.9 Caveats and Restrictions

- The Budgets administrator account must exist and have the *admin* role at all times. Make sure you never remove the *admin* role from your administrator account. If you have no administrator with *admin* role, you cannot use Budgets. If you do not have another administrator account with the *admin* role, do not disable your administrator account as shown in section 2.11, “Changing Budgets Administrator to New Username”, on page 58, step 3, Permanently disable pbsadmin.
- Soft walltime is not supported.
- Shrink-to-fit jobs are not supported.
- If the license server is not reachable, jobs will continue to run for up to 3 hours. After that, jobs cannot start or be reconciled.
- In postpaid mode, a job that is deleted via `qdel -Wforce` is not billed, because it has no *E* record.
- If, in postpaid mode, two groups invest in the same user or project account, but the first group's investment serves only to bring the account from a negative value up to zero, the second group is given full ownership if you switch to prepaid mode at a time that is not on a period boundary. You can avoid this by always switching between modes on a period boundary.

1.10 Troubleshooting

1.10.1 Using Logfiles for Troubleshooting

1.10.1.1 Using Budgets Logfile

Look in the Budgets server log for information about Budgets. Budgets writes its logfile to `/var/spool/am/<Budgets server hostname>_<value of AM_PORT>_server.log`.

Each day, Budgets automatically renames old log files to "<original filename>-<year>-<month>-<day of month>". So if Budgets writes a log file named "/var/spool/am/myserverhost_8000_server.log", and renames it on the 14th of March 2022, the new name is "/var/spool/am/myserverhost_8000_server.log-2022-march-14".

This file lists the requests made to the Budgets server and the resulting actions, and information about problems. Some typical problems and their indicators:

- License has expired: logfile shows "license unavailable"
- A cluster name is different from its associated PBS server : logfile shows "could not resolve hostname <cluster name>"
- A request from an unauthenticated user: logfile shows "unable to login. Username or password is incorrect'
- A user tries to use a project they’re not a member of : logfile shows "user <username> is not authorized for <project name> project"

1.10.1.2 Using PBS Server Logfile

Look in the PBS server log for logging by the Budgets hooks am_hook and am_hook_periodic. The default location for PBS server logs is `$PBS_HOME/server_logs`. See "Event Logging" on page 428 in the PBS Professional Administrator's Guide.

1.10.2 Symptoms

- Symptoms of losing connection with the AMS module:
  - If users can no longer log into or out of Budgets, the connection with the AMS module may have been lost.
  - If Budgets stops jobs from running, check the Budgets logfile or a job comment. If you see Budgets complaining about "connection refused", that means Budgets can't reach the AMS module.
  - If you reinstall the AMS module, that breaks its connection with Budgets.

  To reestablish the connection, run this script as root:

  `/opt/am/libexec/am_auth_register`
- Symptom of insufficient credit:
  - A job returns an error saying there is not enough credit

1.11 Formats in Budgets

1.11.1 Name Formats

- Name format for projects, groups, periods:

  Allowed characters: a-z,A-Z,0-9,_,-,.,$

  Max length: 256 characters
- Name format for service units:

  Allowed characters: a-z,A-Z,0-9,_,$

  Max length: 30 characters
- Name format for usernames is OS-dependent

2 Installing and Upgrading Budgets

2.1 Supported Platforms

2.1.1 OpenSSL Requirement

PBS requires OpenSSL 1.1.1. If this is not already present on your platform, you must install it.

2.1.2 PBS Components

PBS Professional is made up of the following components:

- PBS Professional server/scheduler daemon on PBS Professional server/scheduler host/head node
- PBS Professional MoM daemon on execution host/compute node, with the following options:
  - On premise
  - Burst in cloud via PBS Cloud (optional)
- PBS Professional client commands on PBS submission host/client host
- PBS Professional communication daemon on communication host
- PBS Cloud module on service node (where AMS module runs) (optional)
- Budgets server on Budgets head node (optional)
- Budgets AMS module on service node (where PBS Cloud module runs) (optional)
- Budgets client commands on Budgets client host (optional)
- Simulate module:
  - When using PBS Cloud, Simulate must be installed on PBS Professional server/scheduler host
  - When not using PBS Cloud, Simulate can be installed on any supported host

2.1.3 Supported Platforms for PBS Components

PBS components are supported on the following platforms. A **(d)** indicates that support is deprecated:

Table 2-1: Supported Platforms

Maker	Version	Chip set	Components							
			PBS Professional				Cloud + AMS		Budgets	Simulate
			Server Sched	MoM on prem	Comm	Client cmds	Cloud module + AMS	MoM burst node	Head node + client cmds	Head node
CentOS	7	x86_64	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No
	7	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	No
Red Hat Enterprise Linux RHEL	7	x86_64	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
	7	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
	7 MLS	x86_64	Yes	Yes	Yes	Yes	No	No	No	No
	8	x86_64	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
	8	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
Rocky Linux	8	x86_64	Yes	Yes	Yes	Yes	No	Yes	No	No
	8	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	No
SUSE SLES	12	x86_64	Yes	Yes	Yes	Yes	Yes *	Yes	Yes	Yes
	12	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	No
	15	x86_64	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes
	15	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
Ubuntu	18.04	x86_64	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes
	18.04	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
	20.04	x86_64	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes
	20.04	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
HPE Cray Shasta	1.1 SLES 15	x86_64	Yes	Yes	Yes	Yes	Yes *	No	Yes *	Yes
	1.1 RHEL 7	x86_64	Yes	Yes	Yes	Yes	No	No	No	Yes
NEC SX-Aurora TSUBASA			Yes	Yes	Yes	Yes	No	No	No	Yes
Windows	10 Pro	x86_64	No	Yes	No	Yes	No	Yes	No	No

Table 2-1: Supported Platforms

Maker	Version	Chip set	Components							
			PBS Professional				Cloud + AMS		Budgets	Simulate
			Server Sched	MoM on prem	Comm	Client cmds	Cloud module + AMS	MoM burst node	Head node + client cmds	Head node
	11 Pro	x86_64	No	Yes	No	Yes	No	Yes	No	No
	Server 2016	x86_64	No	Yes	No	Yes	No	Yes	No	No
	Server 2019	x86_64	No	Yes	No	Yes	No	Yes	No	No

2.1.3.1 * SLES Restrictions for Cloud and Budgets Nodes

The following restrictions apply when using SLES on service node host for PBS Cloud or head node host for Budgets:

- Each SLES host must be registered with the SUSE Customer Center via SUSEConnect, and have a support contract. This happens automatically for cloud nodes.
- SLES hosts require Docker Enterprise Edition.

2.1.4 Supported Platforms for Nodes Burst in Cloud

- Linux: any Linux platform that supports both PBS MoM and `cloud-init`
- Windows: 10, Server 2012

All versions of `cloud-init` are supported.

2.1.5 Restrictions on Simulate Module Location when Using PBS Cloud

If you will use the PBS Cloud module, you must install Simulate on the PBS Professional server/scheduler host (the PBS Professional head node).

2.1.6 Hosts for Budgets Client Commands

Any host where you install just the client commands must be able to reach the Budgets server, and must be a supported platform for the Budgets client commands.

2.2 Recommended Configurations

Budgets is typically configured with a *head node* (where the PBS Professional server and the Budgets server run) and a *service node* (where PBS Cloud and the AMS module run). We prefer not to run Docker on a heavily loaded PBS server host, so we typically put the elements requiring Docker on the service node.

Head node and service node can be one of either:

- Both on premises
- Both in cloud

Do not put one on premises and one in the cloud.

There are no restrictions on client command-only hosts.

2.2.1 Installation Directory

The default location for the Budgets server is `/var/spool/am`. You can install the Budgets server in the default location or a non-default location of your choice. The AMS module is always installed in the same location; this location is controlled by the AMS installer.

2.2.2 Recommended Configuration for Larger Installations

For larger installations using on premises hosts with optional cloud bursting:

- Head, service, and first N execution nodes are on premises:
  - On head node, PBS server daemon, PBS scheduler daemon, and Budgets server
  - On service node, AMS module running in container, and PBS Cloud running in separate container
  - Execution hosts running MoM daemons
- Cloud nodes for extra execution nodes
- VPN connection to the cloud you will use
- Client commands go on any Linux host
- All components are mix-and-match (with Docker restriction)

2.2.3 Recommended Configuration for Smaller Installations

For smaller installations and cloud-only installations where the workload is low enough:

- All components can be hosted in the cloud
- All components can run on the same node
- You can run Docker on the same node as the PBS server/scheduler
- You can also run a cloud head node and separate cloud service node:
  - Cloud head node, running PBS Professional server/scheduler and Budgets server
  - Cloud service node, running AMS module in container, and PBS Cloud in separate container
- Client commands go on any Linux host, but a user must be able to reach the Budgets port on the cloud host
- No VPN is required for this configuration

2.3 Whether or Not to Start with Failover

Consider configuring Budgets for failover. Without failover, the `AM_HOME` directory is on a local drive, but with failover, it's on a separate host. We recommend doing a fresh install for failover, which means starting with an empty database. For failover configuration instructions, see section 2.9, “Configuring Budgets for Failover”, on page 53.

2.4 Prerequisites

2.4.1 Altair Software Components

- Budgets server
- Budgets client commands
- Budgets authentication module (AMS)
- PBS Professional 2022.1.0 or later, installed and running
  - PBS Professional server/scheduler(s)/comm(s)
  - PBS Professional MoM(s)
  - PBS Professional client commands
- Altair License Manager 14.5.1 or newer, installed and running
- PBSProNodes 20.0 license features

2.4.2 Third-party Software Components

- docker-ce v19.x or later for most systems
- docker-ee v19.x or later for SLES
- python3
- python3-pip
- openssl

2.4.3 Job Requirements

Each job must request the compute resources that are used in the billing formulas used at that complex. For the default formula, this means walltime and ncpus. Make sure that every PBS job requests ncpus and walltime when it runs. Each job can have these set at submission by the job submitter or later via `qalter`, can inherit a value from the server or queue, or can be assigned a value by a hook. For ncpus, the server attribute default_chunk.ncpus may take care of the requirement.

Job walltime:

- If a job's walltime is extended, Budgets takes that into account.
- Soft walltime is not supported.
- Shrink-to-fit jobs are not supported.

2.5 Installation Steps for All Locations

Follow the steps in this section no matter where you are installing PBS Cloud.

Follow the steps in the order they are presented: when it comes up, the Budgets server needs use the passwords and certificates to communicate with the AMS module, and needs to verify the various accounts.

2.5.1 Create Required User Accounts

2.5.1.1 Budgets Administrator

Budgets requires an administrator. The administrator configures Budgets.

We recommend that the username for the administrator account be *pbsadmin* (same account used for PBS administrator). You can use any username for the Budgets administrator. Where you see "pbsadmin" in the instructions, substitute the actual administrator username.

You can install and configure Budgets using pbsadmin for the administrator username, then switch to another username later. See section 2.11, "Changing Budgets Administrator to New Username", on page 58.

2.5.1.1.i Requirements for Administrator Account

- This account must exist and have the *admin* role at all times. Make sure you never remove the *admin* role from your administrator account. If you have no administrator with *admin* role, you cannot use Budgets.
- The administrator account should not be used for the teller.
- The home directory for the administrator should exist on the PBS server host, and on the Budgets host, if it is a separate machine.
- Administrator account must have an account on the PBS server host, and on the Budgets host, if it is a separate machine.
- Administrator should be able to `ssh` to the Budgets server host without a password. Administrator must have passwordless `ssh` set up from the PBS server host to the Budgets server host. We cover this in section 2.5.3, "Set Up Passwordless SSH for Administrator and Teller", on page 35.

2.5.1.2 Teller

Budgets requires a teller user to process its service unit transactions. When the Budgets hook performs transactions, it does so as the teller.

2.5.1.2.i Requirements for Teller Account

- We recommend that the username for the teller account be *amteller*
- Teller should be a dedicated account used only for the *teller* role
- Teller account must have an account on the PBS server host, and on the Budgets host, if it is a separate machine.
- Teller should be able to `ssh` to the Budgets server host without a password. Teller must have passwordless `ssh` set up from the PBS server host to the Budgets server host. We cover this in section 2.5.3, "Set Up Passwordless SSH for Administrator and Teller", on page 35.
- The teller account should not be used for pbsadmin
- The teller account does not need to be root or administrator

2.5.1.3 Database User

Budgets requires a database user for its database.

2.5.1.3.i Requirements for Database User Account

- We recommend that the username for the database user account be *pbsdata*.
- The pbsdata account should have an ID <1000 so that any processes which run under this user are protected from the Out Of Memory (OOM) killer and run with the correct level of privilege.

2.5.1.4 Job Submitters

Users who submit jobs to PBS Professional have to exist on the system where Budgets is installed, but these users can be added to Budgets after installation.

2.5.1.4.i Requirements for Job Submitters

- Job submitters must already be able to run jobs in a PBS complex.
- Each user you add to Budgets should already have an entry in the password file, with a password set, and a home directory on the Linux system where Budgets is installed.

2.5.1.5 Configuring Required Accounts for Budgets

- Add pbsadmin as the Budgets administrator, and set a password:

  ```
  adduser -u 901 pbsadmin
  passwd pbsadmin <password>
  ```

- Add amteller as the Budgets teller, and set a password:

  ```
  adduser amteller
  passwd amteller <password>
  ```

- Add pbsdata as the Budgets database user, and set a password:

  ```
  adduser -u 900 pbsdata
  passwd pbsdata <password>
  ```

2.5.2 Allow Interaction with PBS Professional

In order to work on hooks, you have to be root, so we add specific actions to the `sudoers` file on the Budgets and PBS server hosts for pbsadmin to work as root when using `amgr` and `qmgr` to import and export hook files.

If you will install Budgets in a non-default location, make sure that `AM_EXEC` is set correctly.

2.5.2.1 Budgets Server and PBS Server on Same Host

On the Budgets/PBS server host, edit /etc/sudoers, and add the following lines. Replace the $AM_EXEC and $PBS_EXEC variables with the actual paths.

- Allow Budgets administrator to act as root for Budgets commands:
  ```
  Cmnd_Alias AM_SERVER_CMD = $AM_EXEC/python/bin/python3 $AM_EXEC/hooks/pbs/pbs_set_formula.py*
  ```
- Allow Budgets administrator to set the formulas as root:
  ```
  Defaults!AM_SERVER_CMD !requiretty
  ```
- Allow teller to get a security token:
  ```
  Cmnd_Alias AM_CLIENT_CMD = $AM_EXEC/python/bin/amgr sshlogin
  ```
- Allow amgr command to update hook formulas:
  ```
  Cmnd_Alias BUDGETS_IMPORTS = $PBS_EXEC/bin/qmgr -c i h am_hook application/x-config default
      .am/tmp*, $PBS_EXEC/bin/qmgr -c i h am_hook_periodic application/x-config default .am/tmp*,
      $PBS_EXEC/bin/qmgr -c export hook am_hook application/x-config default
  ```
- Allow the Budgets administrator account to act as root for the qmgr commands listed above:
  ```
  <budget administrator> ALL=(root) NOPASSWD: BUDGETS_IMPORTS
  ```
- Allow hooks to work in the background with no tty interface:
  ```
  Defaults!AM_CLIENT_CMD !requiretty
  ```
- Allow hooks to work in the background with no tty interface:
  ```
  Defaults!BUDGETS_IMPORTS !requiretty
  ```

2.5.2.2 Budgets Server and PBS Server on Separate Hosts

2.5.2.2.i Changes to sudoers on Budgets Server Host

On the Budgets server host, edit /etc/sudoers, and add the following lines. Replace the $AM_EXEC and $PBS_EXEC variables with the actual paths.

- Allow Budgets administrator to act as root for the qmgr commands listed above:
  ```
  Cmnd_Alias AM_SERVER_CMD = $AM _EXEC/python/bin/python3 $AM_EXEC/hooks/pbs/pbs_set_formula.py*
  ```
- Allow the Budgets administrator to set the formulas as root:
  ```
  Defaults!AM_SERVER_CMD !requiretty
  ```

2.5.2.2.ii Changes to sudoers on PBS Server Host

On the PBS server host, edit /etc/sudoers, and add the following lines. Replace the $AM_EXEC and $PBS_EXEC variables with the actual paths. We give an example showing default paths below:

- Allow teller to get a security token:
  ```
  Cmnd_Alias AM_CLIENT_CMD = $AM_EXEC/python/bin/amgr sshlogin
  ```
- Allow amgr command to update hook formulas:
  ```
  Cmnd_Alias BUDGETS_IMPORTS = $PBS_EXEC/bin/qmgr -c i h am_hook application/x-config default
      .am/tmp*, $PBS_EXEC/bin/qmgr -c i h am_hook_periodic application/x-config default .am/tmp*,
      $PBS_EXEC/bin/qmgr -c export hook am_hook application/x-config default
  ```
- Allow the Budgets administrator account to act as root for the qmgr commands listed above:
  ```
  <budget administrator> ALL=(root) NOPASSWD: BUDGETS_IMPORTS
  ```
- Allow hooks to work in the background with no tty interface:
  ```
  Defaults!AM_CLIENT_CMD !requiretty
  ```
- Allow hooks to work in the background with no tty interface:
  ```
  Defaults!BUDGETS_IMPORTS !requiretty
  ```

2.5.3 Set Up Passwordless SSH for Administrator and Teller

The administrator needs to have passwordless ssh available from the Budgets server host to the PBS server host. The teller needs to have passwordless ssh available from the PBS server host to the Budgets server host.

2.5.3.1 Setting Up Passwordless SSH for Administrator

To give the administrator passwordless ssh from the Budgets server host to the PBS server host, generate a public authentication key at the Budgets server host and append it to the ~/.ssh/authorized_keys file at the PBS server host. Here are the steps:

1. Log in to the Budgets server host as the administrator
2. Check for an existing SSH key pair:

   ```
   ls -al ~/.ssh/id_*.pub
   ```
3. If you find existing keys, you can use those, or you can back up the old keys and generate a new pair. If you don't find existing keys, generate a new SSH key pair:

   ```
   ssh-keygen
   ```
4. Copy the contents of id_rsa.pub
5. Log in to the PBS server as the administrator
6. In the home directory, check for the .ssh directory. If it does not exist, create it:

   ```
   mkdir -p .ssh
   cd .ssh/
   ```
7. Create the authorized_keys file in the .ssh directory:
   a. Paste the contents of id_rsa.pub that you copied from the Budgets server host
   b. Save the file as "authorized_keys"
8. Change the permission of authorized_keys to *600*:

   ```
   chmod 600 authorized_keys
   ```

2.5.3.2 Setting Up Passwordless SSH for Teller

To give the teller passwordless ssh from the PBS server host to the Budgets server host, generate a public authentication key at the PBS server host and append it to the ~/.ssh/authorized_keys file at the Budgets server host. Here are the steps:

1. Log in to the PBS server host as the teller
2. Check for an existing SSH key pair:

   ```
   ls -al ~/.ssh/id_*.pub
   ```

3. If you find existing keys, you can use those, or you can back up the old keys and generate a new pair. If you don't find existing keys, generate a new SSH key pair:

   ```
   ssh-keygen
   ```

4. Copy the contents of id_rsa.pub
5. Log in to the Budgets server as the teller
6. In the home directory, check for the .ssh directory. If it does not exist, create it:

   ```
   mkdir -p .ssh
   cd .ssh/
   ```

7. Create the authorized_keys file in the .ssh directory:
   a. Paste the contents of id_rsa.pub that you copied from the PBS server host
   b. Save the file as "authorized_keys"
8. Change the permission of authorized_keys to *600*:

   ```
   chmod 600 authorized_keys
   ```

2.5.4 Set Budgets Paths

Append executable path to PATH environment variable for all users of Budgets (administrator, investors, managers, teller, job submitters). You can set this in /etc/bashrc:

```
export PATH=$PATH:$AM_EXEC/python/bin
```

For the default path, this is:

```
export PATH=$PATH:/opt/am/python/bin
```

2.6 Installation Steps for Default Location

2.6.1 Install Utilities and Docker

Install utilities and `docker` on the service node. The directory is not important.

- For CentOS or RedHat:

  Log in as root to the service node (the machine where the AMS module is to be installed).

  ```
  yum install -y yum-utils
  yum-config-manager --add-repo https://download.docker.com/linux/centos/docker-ce.repo
  yum install docker-ce docker-ce-cli containerd.io
  systemctl enable docker
  systemctl start docker
  yum install python3 python3-pip
  yum install openssl
  ```

- For SLES12 or 15:

  Log in as root to the service node (the machine where the AMS module is to be installed).

  For SLES 12:

  ```
  sudo SUSEConnect -p sle-module-containers/12/x86_64 -r ''
  ```

  For SLES 15:

  ```
  sudo SUSEConnect -p sle-module-containers/15.1/x86_64 -r ''
  ```

  ```
  sudo zypper install docker
  sudo systemctl enable docker.service
  sudo systemctl start docker.service
  ```

  Configure the firewall to allow forwarding of Docker traffic to the external network:

  ```
  Set FW_ROUTE="yes" in /etc/sysconfig/SuSEfirewall2
  zypper install python3-pip
  ```

- For Ubuntu:

  Log in as root to the service node (the machine where the AMS module is to be installed).

  ```
  sudo apt-get update
  sudo apt-get install apt-transport-https ca-certificates curl gnupg-agent software-proper-
      ties-common
  curl -fsSL https://download.docker.com/linux/ubuntu/gpg | sudo apt-key add -
  sudo apt-key fingerprint 0EBFCD88
  ```

  The key should match the second line in the output; validate the last 8 characters. Example of second line:

  9DC8 5822 9FC7 DD38 854A E2D8 8D81 803C 0EBF CD88

  ```
  sudo add-apt-repository "deb [arch=amd64] https://download.docker.com/linux/ubuntu
      $(lsb_release -cs) stable"
  sudo apt-get update
  sudo apt-get install docker-ce docker-ce-cli containerd.io
  sudo apt-get install python3-pip
  ```

  This can install a number of required dependencies, and may take a few minutes.

  ```
  sudo apt-get install openssl
  sudo systemctl enable docker.service
  ```

```
sudo systemctl start docker.service
```

2.6.2 Download Budgets Server and AMS Modules

1. Log in as root to the Budgets server host
2. Go to the default installation location:

   ```
   # cd /var/spool
   ```

3. On the Budgets server host, download the main file containing both the Budgets server and the AMS module. The filename has the following format:
   PBSPro-budget-server_<release number>-<OS>_x86_64.tar.gz
   For example:
   PBSPro-budget-server_2022.1.0-CentOS7_x86_64.tar.gz
4. Untar the main file:
   tar xvfz PBSPro-budget-server_<release number>-<OS>_x86_64.tar.gz
   For example:

   ```
   tar xvfz PBSPro-budget-server_2022.1.0-CentOS7_x86_64.tar.gz
   ```

   This creates the following:
   - File named "ams-installer.tar.gz" containing the AMS installer
   - Directory named "am" containing the Budgets server module
5. Copy `ams_installer.tar.gz` over to the service node

2.6.3 Install AMS Module on Service Node

Install the AMS module on the service node. You can start in any directory.

1. Untar the AMS installer file:

   `Tar xvfz ams-installer.tar.gz`

   This gives a directory named "ams-installer", containing:

   - A file named "README.md "
   - A package named "ams-installer.zip"

2. Unzip `ams-installer.zip`:

   `unzip ams-installer.zip`

   This gives a directory named "ams-installation", containing:

   - Directory named "packages" containing the AMS package of folders and configuration files
   - Directory named "pbsworks-packager" containing the Python module that installs AMS

3. Change to `ams-installation` directory:

   `cd ams-installation`

4. Use the Python module to install AMS:

   `python3 -m pip install --upgrade --ignore-installed pbsworks-packager/`
   `/usr/local/bin/pkgr` (Please stay in the AMS installer directory for this step)

5. Answer the questions in the dialogue:

   a. Choose option: 0 (choose the AMS package)

   b. Hit *Enter* until you've seen the whole license agreement, then answer *Yes* to accept

   c. Select *Enter* to continue

   d. Choose Option: 1 (yes, add hostname resolution)

      <Budgets server hostname>

      <Budgets server IP address>

   e. Choose Option: 0 (no, stop adding hostname resolution)

   f. Install Location: <Budgets server hostname>

   g. Authentication Server: <authentication daemon hostname>

   h. Authentication Port (this is the port for the authentication daemon, typically `sshd`): <port number>

   i. Provide administrator username: <administrator username>

   j. Install Path: <install path>

6. Once installation completes check the AMS service status:

   `systemctl status altaircontrol`

2.6.4 Enable Passwords in Docker Container Network

To allow administrators and job submitters to use a password to log into Budgets, make it so that Budgets can authenticate users via passwords and `ssh`. This way users can use their password entry in `/etc/passwd` to log into Budgets.

On the service node:

1. Edit /etc/ssh/sshd_config and add the following lines:

```
Match Address 10.5.0.0/24
PasswordAuthentication yes
```

2. Make sshd reread its configuration file, and restart it:

```
systemctl daemon-reload
systemctl restart sshd
```

2.6.5 Create Certificates for Budgets Daemon Communication Encryption

On the Budgets server host, create the certificates required to encrypt communication between the Budgets and database daemons:

1. Make required directory:

```
cd /home/pbsadmin/
mkdir budget_certificates
export AM_DBUSER=<database user; default is pbsdata>
```

2. Create a key pair that will serve as both the root CA and the server key pair. This key pair is for 10 years (3650 days):

```
openssl req -new -x509 -days 3650 -nodes -out budget_certificates/ca.crt -keyout
    budget_certificates/ca.key -subj "/CN=root-ca"
    Generating a 2048 bit RSA private key
    ...
    writing new private key to 'budget_certificates/ca.key'
    ...
```

3. Create the server key and CSR:

```
openssl req -new -nodes -out server.csr -keyout budget_certificates/server.key -subj "/CN=local-
    host"
    Generating a 2048 bit RSA private key
    ...
    writing new private key to 'budget_certificates/server.key'
    ...
```

4. Sign the CSR using the root key:

```
openssl x509 -req -in server.csr -days 3650 -CA budget_certificates/ca.crt -CAkey
    budget_certificates/ca.key -CAcreateserial -out budget_certificates/server.crt
    Signature ok
    subject=/CN=localhost
    Getting CA Private Key
```

5. Create client certificate for database user (typically pbsdata):

```
openssl req -new -nodes -out client.csr -keyout budget_certificates/client.key -subj
    "/CN=${AM_DBUSER}"
    Generating a 2048 bit RSA private key
    ...
    writing new private key to 'budget_certificates/client.key'
    ...
openssl x509 -req -in client.csr -days 3650 -CA budget_certificates/ca.crt -CAkey
    budget_certificates/ca.key -CAcreateserial -out budget_certificates/client.crt
    Signature ok
    subject=/CN=pbsdata
    Getting CA Private Key
```

6. Remove unneeded intermediate files:

```
rm -f server.csr client.csr
```

7. Set suitable permissions to protect certificates:

```
chmod og-rwx budget_certificates/*
```

8. View files:

```
cd budget_certificates/
ls -l
    total 28
    -rw-------. 1 root root 1090 Jan 7 14:45 ca.crt
    -rw-------. 1 root root 1704 Jan 7 14:45 ca.key
    -rw-------. 1 root root 17 Jan  7 14:56 ca.srl
    -rw-------. 1 root root 973 Jan  7 14:56 client.crt
    -rw-------. 1 root root 1704 Jan 7 14:55 client.key
    -rw-------. 1 root root 973 Jan  7 14:54 server.crt
    -rw-------. 1 root root 1704 Jan 7 14:52 server.key
pwd
    /home/pbsadmin/budget_certificates
```

2.6.6 Install Budgets Server Module

You can install and configure Budgets using "pbsadmin" as the Budgets administrator username, then switch to a different administrator username later; see section 2.11, “Changing Budgets Administrator to New Username”, on page 58. Install the Budgets server module on the head node (the Budgets server host):

1. Change to new directory created by untarring the main file earlier:

   ```
   cd /var/spool/am/
   ```

2. Run the Budgets installer, and choose the username you want for the Budgets administrator. In our example we use *pbsadmin* for the administrator username:

   ```
   ./install -t server -u pbsadmin -c /home/pbsadmin/budget_certificates
       Installing Budgets
       You have selected server.
       AM_EXEC does not exist. Will make it.
       AM_HOME does not exist. Will make it.
       Installing Budgets server...
       **
       **
       Copying source to /opt/am
       **
       **
       Budgets installed successfully.
       sed -i 's/AMADMIN/pbsadmin/g' /opt/am/db/am_database.sql
       sed -i 's/AMADMIN/pbsadmin/g' /opt/am/libexec/am_postinstall
       sed -i 's|@AM_EXEC@|/opt/am|g' /opt/am/libexec/pbs_budget.service
       sed -i 's|@AM_HOME@|/var/spool/am|g' /opt/am/libexec/pbs_budget.service
       sed -i 's|@AM_SERVER@|testbed|g' /opt/am/libexec/pbs_budget.service
       sed -i 's|@AM_PORT@|8000|g' /opt/am/libexec/pbs_budget.service
       cp -rp /opt/am/libexec/pbs_budget.service /usr/lib/systemd/system/pbs_budget.service
   ```

2.6.7 Set Configuration Parameters

Budgets relies on configuration parameters in the file `/etc/am.conf`. We list the parameters in Table 2-2, “Budgets Configuration Parameters,” on page 44. On the Budgets server host and any client hosts, make sure all of the Budgets configuration parameters are set correctly. Especially make sure that AM_MODE is set to the mode you want, because to change modes you need to restart Budgets. In addition, make sure that AM_AUTH_ENDPOINT and AM_LICENSE_ENDPOINT are set correctly.

2.6.7.1 Budgets Configuration Parameters

Budgets uses the following configuration parameters:

Table 2-2: Budgets Configuration Parameters

Configuration Parameter	Description	Default Value
AM_AUTH_ENDPOINT	Path to AMS module. Format: *<port>@<hostname>*	*9100@<AMS host>*
AM_AUTH_TIMEOUT	Optional. Number of seconds to wait when authenticating. Integer. Set this to a larger value if you have a problem with authentication timeout.	*10*
AM_BALANCE_PRECHECK	Boolean. Directs hook to precheck account balance when job is queued	*False*
AM_DBPORT	Port number for Postgres database	*9876*
AM_DBUSER	Username of database user	*pbsdata*
AM_EXEC	Path to Budgets executables	*/opt/am*
AM_HOME	Home directory for Budgets	*/var/spool/am*
AM_LICENSE_ENDPOINT	Path to license daemon. Format: *<port>@<hostname>*	*6200@<ALM host>*
AM_MODE	Specifies postpaid or prepaid mode	*postpaid*
AM_PORT	Port number on which Budgets listens	*8000*
AM_SERVER	Hostname of Budgets server module host	Host where Budgets server module is installed
AM_WORKERS	Number of workers to spawn. We recommend not changing this setting. For help, contact Altair support.	*2*

2.6.7.2 Example Configuration File

Example of `/etc/am.conf`:

```
AM_PORT=8000
AM_EXEC=/opt/am
AM_HOME=/var/spool/am
AM_WORKERS=2
AM_DBUSER=pbsdata
AM_DBPORT=9876
AM_AUTH_ENDPOINT=9100@my_ams_host
AM_AUTH_TIMEOUT=30
AM_LICENSE_ENDPOINT=6200@my_alm_host
AM_SERVER=my_budget_host
AM_MODE=postpaid
AM_BALANCE_PRECHECK=False
```

2.6.7.3 Caveats and Advice for Budgets Configuration Parameters

- If you change AM_MODE, you must restart Budgets. For procedures to change AM_MODE, see section 3.5, "Changing Between Modes", on page 74.
- Set AM_AUTH_TIMEOUT to a larger value if you have a problem with authentication timeout.

2.6.8 Enable and Start Budgets

- On the Budgets server host, enable and start Budgets:

```
systemctl enable pbs_budget
systemctl start pbs_budget
```

- Check the status of Budgets:

```
systemctl status pbs_budget
```

2.7 Installation Steps for Non-default Location

You must be root to install Budgets. Log in as root.

2.7.1 Set Configuration Parameters

Budgets relies on configuration parameters in the file /etc/am.conf. When you install Budgets in a non-default location, you create the configuration file before you install Budgets. We list the configuration parameters in Table 2-2, "Budgets Configuration Parameters," on page 44. Create the configuration file and make sure that:

- All of the configuration parameters are set correctly
- You set AM_HOME and AM_EXEC to your non-default locations
- You set AM_MODE to the mode you want, because to change modes you need to restart Budgets
- You set AM_AUTH_ENDPOINT and AM_LICENSE_ENDPOINT correctly

Example of /etc/am.conf for non-default locations:

```
AM_PORT=8000
AM_EXEC=/budgets/exec
AM_HOME=/budgets/home
AM_WORKERS=2
AM_DBUSER=pbsdata
AM_DBPORT=9876
AM_AUTH_ENDPOINT=9100@my_ams_host
AM_AUTH_TIMEOUT=30
AM_LICENSE_ENDPOINT=6200@my_alm_host
AM_SERVER=my_budget_host
AM_MODE=postpaid
AM_BALANCE_PRECHECK=False
```

2.7.2 Install Utilities and Docker

1. Install utilities and `docker` on the service node:
   - For CentOS or RedHat:

     Log in as root to the service node (the machine where the AMS module is to be installed).

     ```
     yum install -y yum-utils
     yum-config-manager --add-repo https://download.docker.com/linux/centos/docker-ce.repo
     yum install docker-ce docker-ce-cli containerd.io
     systemctl enable docker
     systemctl start docker
     yum install python3 python3-pip
     yum install openssl
     ```

   - For SLES12 or 15:

     Log in as root to the service node (the machine where the AMS module is to be installed).

     For SLES 12:

     ```
     sudo SUSEConnect -p sle-module-containers/12/x86_64 -r ''
     ```

     For SLES 15:

     ```
     sudo SUSEConnect -p sle-module-containers/15.1/x86_64 -r ''
     sudo zypper install docker
     sudo systemctl enable docker.service
     sudo systemctl start docker.service
     ```

     Configure the firewall to allow forwarding of Docker traffic to the external network:

     ```
     Set FW_ROUTE="yes" in /etc/sysconfig/SuSEfirewall2
     zypper install python3-pip
     ```

   - For Ubuntu:

     Log in as root to the service node (the machine where the AMS module is to be installed).

     ```
     sudo apt-get update
     sudo apt-get install apt-transport-https ca-certificates curl gnupg-agent software-proper-
         ties-common
     curl -fsSL https://download.docker.com/linux/ubuntu/gpg | sudo apt-key add -
     sudo apt-key fingerprint 0EBFCD88
     ```

     The key should match the second line in the output; validate the last 8 characters. Example of second line:

     9DC8 5822 9FC7 DD38 854A E2D8 8D81 803C 0EBF CD88

     ```
     sudo add-apt-repository "deb [arch=amd64] https://download.docker.com/linux/ubuntu
         $(lsb_release -cs) stable"
     sudo apt-get update
     sudo apt-get install docker-ce docker-ce-cli containerd.io
     sudo apt-get install python3-pip
     ```

     This can install a number of required dependencies, and may take a few minutes.

     ```
     sudo apt-get install openssl
     sudo systemctl enable docker.service
     sudo systemctl start docker.service
     ```

2.7.3 Download Budgets Server and AMS Modules

1. Log in as root to the Budgets server host
2. Go to your selected installation location:

   # cd <Budgets server installation directory>
3. On the Budgets server host, download the main file containing both the Budgets server and the AMS module. The filename has the following format:

   PBSPro-budget-server_<release number>-<OS>_x86_64.tar.gz

   For example:

   PBSPro-budget-server_2022.1.0-CentOS7_x86_64.tar.gz
4. Untar the main file:

   tar xvfz PBSPro-budget-server_<release number>-<OS>_x86_64.tar.gz

   For example:

   tar xvfz PBSPro-budget-server_2022.1.0-CentOS7_x86_64.tar.gz

   This creates the following:
   - File named "ams-installer.tar.gz" containing the AMS installer
   - Directory named "am" containing the Budgets server module
5. Copy `ams_installer.tar.gz` over to the service node

2.7.4 Install AMS Module on Service Node

Install the AMS module on the service node. You can start in any directory.

1. Untar the AMS installer file:

   `Tar xvfz ams-installer.tar.gz`

   This gives a directory named "ams-installer", containing:

   - A file named "README.md "
   - A package named "ams-installer.zip"

2. Unzip `ams-installer.zip`:

   `unzip ams-installer.zip`

   This gives a directory named "ams-installation", containing:

   - Directory named "packages" containing the AMS package of folders and configuration files
   - Directory named "pbsworks-packager" containing the Python module that installs AMS

3. Change to `ams-installation` directory:

   `cd ams-installation`

4. Use the Python module to install AMS:

   `python3 -m pip install --upgrade --ignore-installed pbsworks-packager/`
   `/usr/local/bin/pkgr` (Please stay in the AMS installer directory for this step)

5. Answer the questions in the dialogue:

   a. Choose option: 0 (choose the AMS package)

   b. Hit *Enter* until you've seen the whole license agreement, then answer *Yes* to accept

   c. Select *Enter* to continue

   d. Choose Option: 1 (yes, add hostname resolution)

      <Budgets server hostname>

      <Budgets server IP address>

   e. Choose Option: 0 (no, stop adding hostname resolution)

   f. Install Location: <Budgets server hostname>

   g. Authentication Server: <authentication daemon hostname>

   h. Authentication Port (this is the port for the authentication daemon, typically `sshd`): <port number>

   i. Provide administrator username: <administrator username>

   j. Install Path: <install path>

6. Once installation completes check the AMS service status:

   `systemctl status altaircontrol`

2.7.5 Enable Passwords in Docker Container Network

To allow administrators and job submitters to use a password to log into Budgets, make it so that Budgets can authenticate users via passwords and `ssh`. This way users can use their password entry in `/etc/passwd` to log into Budgets.

On the service node:

Edit /etc/ssh/sshd_config and add the following lines:

```
Match Address 10.5.0.0/24
PasswordAuthentication yes
```

Make sshd reread its configuration file, and restart it:

```
systemctl daemon-reload
systemctl restart sshd
```

2.7.6 Create Certificates for Budgets Daemon Communication Encryption

On the Budgets server host, create the certificates required to encrypt communication between the Budgets and database daemons:

1. Make required directory:

```
cd /home/pbsadmin/
mkdir budget_certificates
export AM_DBUSER=pbsdata
```

2. Create a key pair that will serve as both the root CA and the server key pair. This key pair is for 10 years (3650 days):

```
openssl req -new -x509 -days 3650 -nodes -out budget_certificates/ca.crt -keyout
    budget_certificates/ca.key -subj "/CN=root-ca"
    Generating a 2048 bit RSA private key
    ...
    writing new private key to 'budget_certificates/ca.key'
    ...
```

3. Create the server key and CSR:

```
openssl req -new -nodes -out server.csr -keyout budget_certificates/server.key -subj "/CN=local-
    host"
    Generating a 2048 bit RSA private key
    ...
    writing new private key to 'budget_certificates/server.key'
    ...
```

4. Sign the CSR using the root key:

```
openssl x509 -req -in server.csr -days 3650 -CA budget_certificates/ca.crt -CAkey
    budget_certificates/ca.key -CAcreateserial -out budget_certificates/server.crt
    Signature ok
    subject=/CN=localhost
    Getting CA Private Key
```

5. Create client certificate for database user (typically pbsdata):

```
openssl req -new -nodes -out client.csr -keyout budget_certificates/client.key -subj
    "/CN=${AM_DBUSER}"
    Generating a 2048 bit RSA private key
    ...
    writing new private key to 'budget_certificates/client.key'
    ...
openssl x509 -req -in client.csr -days 3650 -CA budget_certificates/ca.crt -CAkey
    budget_certificates/ca.key -CAcreateserial -out budget_certificates/client.crt
    Signature ok
    subject=/CN=pbsdata
    Getting CA Private Key
```

6. Remove unneeded intermediate files:

```
rm -f server.csr client.csr
```

7. Set suitable permissions to protect certificates:

```
chmod og-rwx budget_certificates/*
```

8. View files:

```
cd budget_certificates/
ls -l
    total 28
    -rw-------. 1 root root 1090 Jan 7 14:45 ca.crt
    -rw-------. 1 root root 1704 Jan 7 14:45 ca.key
    -rw-------. 1 root root 17 Jan  7 14:56 ca.srl
    -rw-------. 1 root root 973 Jan  7 14:56 client.crt
    -rw-------. 1 root root 1704 Jan 7 14:55 client.key
    -rw-------. 1 root root 973 Jan  7 14:54 server.crt
    -rw-------. 1 root root 1704 Jan 7 14:52 server.key
pwd
    /home/pbsadmin/budget_certificates
```

2.7.7 Install Budgets Server Module

You can install and configure Budgets using "pbsadmin" as the Budgets administrator username, then switch to a different administrator username later; see section 2.11, “Changing Budgets Administrator to New Username”, on page 58. Install the Budgets server module on the head node:

1. Change to new directory created by untarring the main file earlier:

   cd <selected installation directory>/am/

2. Run the Budgets installer, and choose the username you want for the Budgets administrator. In our example we use *pbsadmin* for the administrator username:

   ./install -t server -u pbsadmin -c /home/pbsadmin/budget_certificates

   For example, if you use the example configuration file in section 2.7.1, “Set Configuration Parameters”, on page 45, you will see the following:

```
Installing Budgets
You have selected server.
AM_EXEC does not exist. Will make it.
AM_HOME does not exist. Will make it.
Installing Budgets server...
**
**
Copying source to /budgets/exec
**
**
Budgets installed successfully.
sed -i 's/AMADMIN/pbsadmin/g' /budgets/exec/db/am_database.sql
sed -i 's/AMADMIN/pbsadmin/g' /budgets/exec/libexec/am_postinstall
sed -i 's|@AM_EXEC@|/budgets/exec|g' /budgets/exec/libexec/pbs_budget.service
sed -i 's|@AM_HOME@|/budgets/home|g' /budgets/exec/libexec/pbs_budget.service
sed -i 's|@AM_SERVER@|testbed|g' /budgets/exec/libexec/pbs_budget.service
sed -i 's|@AM_PORT@|8000|g' /budgets/exec/libexec/pbs_budget.service
cp -rp /budgets/exec/libexec/pbs_budget.service /usr/lib/systemd/system/pbs_budget.service
```

2.7.8 Enable and Start Budgets

- On the Budgets server host, enable and start Budgets:

  systemctl enable pbs_budget

  systemctl start pbs_budget

- Check the status of Budgets:

  systemctl status pbs_budget

2.8 Validating Budgets

1. Log in as pbsadmin
2. Test authentication:

   ```
   amgr login
   ```

3. List users (pbsadmin and amteller):

   ```
   amgr ls user -l
   ```

2.9 Configuring Budgets for Failover

Budgets uses Pacemaker and Corosync to manage failover for the Budgets and data service daemons. You set up a primary Budgets server and a secondary Budgets server, and a shared filesystem used by either one and available to both, as a *failover cluster*. The primary normally handles all server traffic, but the secondary takes over and becomes active if the primary becomes unavailable. Failover for the Budgets daemon and the data service daemon happens together. Budgets starts the data service on the same host where the Budgets daemon runs. Pacemaker and Corosync manage the flow of traffic so that it goes to the active server and database.

2.9.1 Prerequisites for Configuring Budgets Failover

2.9.1.1 Third-party Software Prerequisites

- Pacemaker 1.1.23
- Corosync 2.4.5 or later
- pcs 0.9.169

2.9.1.2 Budgets Server Host Prerequisites

- Budgets server hosts must be identical
- Both server hosts must have access to shared filesystem
- Each server host should have two network connections:
  - Dedicated private ethernet connection that Pacemaker and Corosync use to manage host state
  - Public network that Budgets client commands will use for communication traffic with Budgets server
- Each server host should have two hostnames:
  - Private hostname for use with private ethernet connection, for example "PrimaryFailover" and "Secondary-Failover"
  - Public hostname for use with client commands, for example "Primary" and "Secondary"
- Same version of Budgets on both servers
- Accounts for administrator, investors, managers, and teller must be identical on both hosts

2.9.1.3 Filesystem Prerequisites

- Shared AM_HOME filesystem on a third host, that is mounted on both Budgets server hosts and always available to both hosts
- No root squash on shared filesystem
- Hostname resolution must work both ways between Budgets server hosts, and between both servers and any other hosts involved, for example PBS server hosts
- The AM_HOME directory must be readable and writable from both servers by the Budgets administrator

2.9.1.4 Optional

- STONITH script, if required. The administrator writes this script.

2.9.1.5 Notes

- There are no prerequisites for the service node.

2.9.2 Installing Corosync, Pacemaker, and pcs

On each Budgets server host:

1. Log into each Budgets server host as root.
2. Install Budgets if it is not already installed. See section 2.6, “Installation Steps for Default Location”, on page 37.
3. Install Pacemaker, Corosync, and pcs.
4. When you install Pacemaker, the installation creates the hacluster account, which is the proxy user for Pacemaker. You need to give hacluster a password on each server host:

   ```
   passwd hacluster
   <password for hacluster account>
   ```

5. Create a budget directory in the ocf library:

   ```
   mkdir /usr/lib/ocf/resource.d/budgetmanager
   ```

6. Copy ocf files am_ocf and am_data_ocf from the Budgets package to the budget directory:

   ```
   cp /root/am/failover/budgetmanager/* /usr/lib/ocf/resource.d/budgetmanager/
   ```

7. Set the permissions for the budget directory:

   ```
   chmod -R +x /usr/lib/ocf/resource.d/budgetmanager
   ```

2.9.3 Configuring Pacemaker

1. If Budgets is running on any host, stop Budgets:

   ```
   systemctl disable pbs_budget
   systemctl stop pbs_budget
   ```

2. Log into the primary Budgets server host as root

3. Authorize Pacemaker to use the server hosts, using their private hostnames:

   ```
   pcs cluster auth <private primary hostname> <private secondary hostname>
   ```

4. Create the failover cluster, name it "am_cluster", and start it, using the private hostnames:

   ```
   pcs cluster setup --start --name am_cluster <private primary hostname> <private secondary host-
       name>
   ```

5. Set the quorum policy to *ignore*:

   ```
   pcs property set no-quorum-policy=ignore
   ```

6. Set whether or not stonith is enabled. If you have a STONITH script and want to use it, you can enable stonith. If not, disable it:

   ```
   pcs property set stonith-enabled=false
   ```

7. Create the virtual_ip resource to represent a virtual IP address. This IP address should be exclusively allocated for this purpose and not used by any physical host on your network. This is the IP address that client commands will use to connect to the active Budgets server over the public network. Pacemaker and Corosync direct traffic from this IP address to whichever server is active:

   ```
   pcs resource create virtual_ip ocf:heartbeat:IPaddr2 ip=<virtual IP address> cidr_netmask=32
       nic=<nic-name-of-public-network> op monitor interval=10s
   ```

8. Create the amserver resource to represent the Budgets daemon. Note that here we are assuming `am.conf` is in `/etc`. Make sure you use the appropriate location:

   ```
   pcs resource create amserver ocf:budgetmanager:am_ocf conf=/etc/am.conf op monitor interval=15s
   ```

9. Add a constraint to Pacemaker so that it always keeps the virtual_ip and amserver resources on the same host. When one moves, the other goes with it:

   ```
   pcs constraint colocation add amserver virtual_ip INFINITY
   ```

10. Make the primary server host be the preferred server host:

    ```
    pcs constraint location amserver prefers <primary>
    ```

11. Budgets is automatically started on the primary server host. You do not have to start Budgets.

2.9.4 Caveats and Recommendations for Failover

- Make sure only one Budgets server daemon is running at a time. Do not start a second Budgets server. If two instances of Budgets are active at the same time, the database will become corrupted.
- Make sure that the shared `AM_HOME` directory is always available on both the primary and secondary server hosts. Do not prevent either host from reaching `AM_HOME`.

2.9.5 Starting, Stopping, and Getting Status of Budgets with Failover Configured

- To start Budgets when failover is configured:

  On each Budgets server host, in any order:

  ```
  pcs cluster start
  ```

- To stop Budgets when failover is configured, first stop the secondary, then the primary:

  ```
  pcs cluster stop <secondary server host>
  pcs cluster stop <primary server host>
  ```

- To check the status of Budgets when failover is configured:

  ```
  pcs cluster status
  ```

2.10 Upgrading Budgets

1. Log in to the Budgets server as root
2. Turn off scheduling in all associated PBS Professional complexes
3. Disable all PBS queues:

   qmgr -c 'set queue <queue name> enabled=false'
4. Allow all jobs to finish, or kill them
5. If necessary, reconcile all jobs:

   amgr reconcile [options]

   See section 4.3.6, "Reconciling Service Units", on page 130
6. Stop Budgets (ideal for backup, but not essential)

   systemctl stop pbs_budget
7. Back up /var/spool/am
8. Make a copy of the formula file used for each cluster. If you don't have these on hand, export them at each PBS server host:

   qmgr -c 'export hook am_hook application/x-config default' > am_hook.json
9. If necessary, create certificates; see Create Certificates for Budgets Daemon Communication Encryption
10. Allow Budgets to work with PBS Professional by updating sudoers file; see section 2.5.2, "Allow Interaction with PBS Professional", on page 33
11. Untar the new install package; this creates the am directory
12. Change to the am directory and install Budgets (we include the **-c /home/pbsadmin/budget_certificates/** option here so that the installer uses the new certificates; if you have not changed the certificates you can leave this option out):

    cd am

    ./install -t upgrade -c /home/pbsadmin/budget_certificates/
13. Installer asks whether scheduling is disabled; enter "Y"

    Installer actions:

    - The installer backs up your database. If this fails, it aborts the upgrade. If the upgrade fails, the installer restores the backup you just made, and you can reinstall the older version of Budgets to return to operation. You can install it in place over the existing data, and it will pick up where it left off.
    - After backing up the data, the installer uninstalls the old Budgets, installs the new one, updates the database schema and updates the data. This could take some minutes if there is a lot of data.
    - The installer updates am.conf.
14. Make sure that all of the settings in section 2.6.7.1, "Budgets Configuration Parameters", on page 44 are set correctly. Note that after an upgrade, the default for AM_MODE is *prepaid*.
15. For each PBS complex, create and configure the am_finished_job resource:

    qmgr -c "c r am_finished_job type=string"

    qmgr -c "set server resources_available.am_finished_job=NA"
16. Restart Budgets:

    systemctl restart pbs_budget

17. This version of Budgets comes with a new hook in a .py file. Configure the hooks; see section 3.2.4, "Create and Configure Budgets Hooks", on page 69
18. Update the formulas for each cluster with the file from its PBS complex:

    ```
    amgr update cluster -n <PBS server> -f <formula filename>
    ```

19. Enable all PBS queues:

    ```
    qmgr -c 'set queue <queue name> enabled=true'
    ```

20. Enable scheduling at each associated PBS complex.

Budgets is ready to track and manage service units.

2.11 Changing Budgets Administrator to New Username

You can install and configure Budgets using one administrator username, then switch to another later. To switch to a new administrator username:

1. Make sure the new administrator account meets the criteria in section 2.5.1.1, "Budgets Administrator", on page 32.

- Create the new administrator username, and set a password:

  ```
  adduser -u 901 <new administrator username>
  passwd <new administrator username> <password>
  ```

2. Add the new account to Budgets, and assign it the *admin* role:

   ```
   amgr add user -n <new administrator username> -r admin -A  <accounting policy> -c <PBS server>  -r
       <role> [-h <group list>] [ -a <active>]
   ```

3. Permanently disable pbsadmin.

   Optional. This is **not recoverable**. You can remove *admin* role from pbsadmin, or deactivate pbsadmin:

   ```
   amgr update user -n pbsadmin -r <new role>
   amgr update user -n pbsadmin -a False
   ```

2.12 Installing Budgets Client Module

You can install just the Budgets client commands on other machines besides the Budgets server host.

2.12.1 Prerequisites for Installing Budgets Client Commands

Any host where you install just the client commands must be able to reach the Budgets server, and must be a supported platform for the Budgets client commands (see the *PBS Professional Release Notes*).

2.12.2 Caveats and Restrictions for Installing Budgets Client Commands

When you extract the client command package, you create a directory with the same name as the one created when you extract the server package. This can overwrite your server directory.

2.12.3 Steps to Install Budgets Client Commands

On any host where you will run only the Budgets client commands:

1. Log in as root
2. Extract the client package:

   # tar -xzvf PBSPro-budget-client_<release number>-<OS>_<chipset>.tar.gz

   For example:

   # tar -xzvf PBSPro-budget-client_2022.1.0-CentOS7_x86_64.tar.gz
3. Change to the directory you just created:

   # cd am
4. Install the client commands:

   # ./install -t client
5. Make sure that /etc/am.conf is identical to the one on the Budgets server host. For example:

   # cat /etc/am.conf

   ```
   AM_PORT=8000
   AM_EXEC=/opt/am
   AM_HOME=/var/spool/am
   AM_WORKERS=2
   AM_DBUSER=pbsdata
   AM_DBPORT=9876
   AM_AUTH_ENDPOINT=9100@my_ams_host
   AM_AUTH_TIMEOUT=30
   AM_LICENSE_ENDPOINT=6200@my_alm_host
   AM_SERVER=my_budget_host
   AM_MODE=postpaid
   AM_BALANCE_PRECHECK=False
   ```
6. Test the client:

   # su - pbsadmin

   $ amgr login

   Password: ****

   $ amgr ls user -l

3 Configuring and Managing Budgets

3.1 Defining Billing Periods

Choose and define your billing periods. We describe billing periods in section 1.7.1, “Periods, Allocation Periods, Billing Periods”, on page 18.

Make sure that periods at the same level do not overlap. For example, if Quarter1 ends March 31st, make sure that Quarter2 does not begin sooner than April 1st.

If you want to create periods with a parent-child relationship, you must create the parent period first. You cannot add a parent to an existing child. For example, if you want Year as the parent and Quarter1, Quarter2, etc., as children, create Year first.

If you create child periods, make sure that they fit within the parent period.

Make sure that your period hierarchy is finalized BEFORE doing any transactions or running any jobs; you cannot update or remove periods once transactions have been performed or jobs have started.

To define each billing period, add it to Budgets:

amgr add period -n <period name> -S <start date> -E <end date> [-p <name of parent period>]

See section 4.2.1.6, “Adding a Period”, on page 83.

3.2 Adding a PBS Complex and Setting its Billing Model

Budgets interacts with the PBS server via two hooks and hook configuration file containing the billing formulas. Budgets uses two identical hooks, named am_hook and am_hook_periodic; both hooks use the same configuration file. The formulas define the *billing model* for that PBS complex. You can set different billing formulas for each PBS complex.

To use a PBS complex with Budgets:

- At the PBS server host, the administrator creates and configures the hooks, and defines the formulas to use when billing
- At the Budgets server host, the administrator adds a cluster data structure to Budgets that will represent the PBS complex, and sets the formulas at the cluster to be the same as the one at the PBS complex

3.2.1 Caveats and Advice on Billing Model

For jobs that run on multiple vnodes, the hook uses the sum of the resources used. The hook does not support calculation of variable rates on multiple vnodes.

In postpaid mode, all transactions are allocated to top-level periods.

3.2.2 Steps to Add Complex and Set Billing Model

1. Log into the Budgets server host
2. Optionally modify the formula file as desired; see section 3.2.3, “Define Billing Formulas”, on page 62
3. Log into the PBS server host
4. If the PBS server host is different from the Budgets server host, copy the hook and formula files from your Budgets installation to the PBS server host
5. At the PBS server host, create and configure the Budgets hooks; see section 3.2.4, “Create and Configure Budgets Hooks”, on page 69
6. At the Budgets server host, add a cluster data structure that will represent the PBS complex and specify the formulas you used for the PBS complex:

   amgr add cluster -n <PBS server> -f <formula filename>

   For example, to add a PBS complex whose server is named HPC1, and use the formulas defined in `formula_hpc1.json`:

   ```
   amgr add cluster -n HPC1 -f formula_hpc1.json
   ```

   See section 4.2.1.5, “Adding a Cluster”, on page 83.
7. At the PBS server host, specify whether you want to separate on premise and cloud costs. See section 3.2.6, “Separating On Premise and Cloud Costs”, on page 71.

3.2.3 Define Billing Formulas

Budgets uses billing formulas, in which you define how service units are calculated. These formulas can be different for each cluster.

3.2.3.1 Billing Formula File and Format

The billing model is defined in a billing formula file in JSON format. We provide a default billing formula file named am_hook.json; you can modify it to fit your needs. Name it <formula file>.json.

You can create formulas using Python.

You must include this line:

```
"auth_user": "amteller",
```

3.2.3.1.i Constants (Numbers)

To use a constant (a number) in a formula, you have to define a constant for it in the "constants" section. You cannot use numbers directly in a formula.

Constants must start with the prefix "CONST_". Make sure you define each constant as a floating point number.

Example 3-1: Formula with variables and a constant

```
{
    "auth_user": "amteller",
    "constants": {
        "cpu_count": "job.ncpus",
        "time_span": "job.walltime",
        "CONST_time": 0.01667
    },
    "formulas": {
        "cpu_hrs": "cpu_count*time_span*CONST_time"
    }
}
```

3.2.3.1.ii PBS Resources and Attributes

If you want to use a PBS resource or attribute as a variable in a formula, you have to define a constant to represent it in the "constants" section. For example, instead of using the ncpus resource directly, define a constant named "cpu_count", and set it to the value of the ncpus resource, as we have done in "Formula with variables and a constant".

You cannot use a resource or attribute directly in a formula. If the value of a PBS attribute or resource has not been set, you cannot access it in a formula.

You can use the following PBS Professional elements:

- Job, server, queue, and node attributes that are of type float or integer
- Built-in or custom resources that are of type float or integer
- Built-in resources that are of type duration: walltime, cput, and eligible_time
- Built-in resources that are of type size: mem and vmem

Note that if the value of an attribute or resource has not been set, you cannot access it.

The syntax for specifying resources in the formula file is different from the syntax you would use in a normal hook:

- Before and while running, job resources are read from the job's Resource_List attribute. After the job runs, job resources are read from the job's resources_used attribute. The syntax for specifying a job resource in the formula file is different from other hook operations:

  job.<resource name>

  For example, to specify what would be job.Resource_List["ncpus"]:

  ```
  job.ncpus
  ```

- Server, queue, and vnode resources are read from the resources_available attribute. The syntax for specifying resources at the server, queue, or vnode is slightly different from other hook operations (you omit the quotes):

  <object>.resources_available[<resource name>]

  For example, to use the value of what would be server.resources_available["charge_rate"] in the usual hook syntax:

  ```
  server.resources_available[charge_rate]
  ```

For jobs that run on multiple vnodes, the hook uses the sum of the resources used across all sister vnodes.

Example 3-2: Formula using job resources and a queue attribute:

```
{
    "auth_user": "amteller",
    "constants": {
        "cpu_count": "job.ncpus",
        "gpu_count": "job.ngpus",
        "time_span": "job.walltime",
        "queue_priority": "queue.Priority",
        "CONST_threshold_prio": 1,
        "CONST_low": 0.5,
        "CONST_high": 1.0
    },
    "formulas": {
        "cpu_hrs": "((cpu_count+gpu_count)*time_span) *
            (queue_priority < CONST_threshold_prio and CONST_low or CONST_high)"
    }
}
```

3.2.3.1.iii Operators

- Logical operators (AND and OR)
- Conditional operators (>,>=,<,<=,==,!=).

3.2.3.1.iv Units

The PBS resources walltime, cput, and eligible_time are in *duration* format (hh:mm:ss). The hook is give the value of these in seconds when used in the formula for the service unit. For example, if a job's walltime is two minutes, the value used in the formula is 120.

The PBS resources mem and vmem are in *size* format (3b, 20kb etc.). The hook converts their values to kb in the service unit formula.

The following table lists the units you can use in a billing formula:

Table 3-1: Units in Billing Formulas

Formula Item	Units	Example
Constants	*Floating point*	12.34
Time-based PBS resources, e.g. walltime, cput, eligible_time	*Integer seconds*	120 (2 minutes)
Memory PBS resources, e.g. mem, vmem	*kb*	1048576kb (1GB)
ncpus, represented as cpu_count	*Integer*	4 (ncpus=4)

When Budgets computes cost data for a cloud job, it uses the data you gave to Budgets via `amgr update cloud-data`. This data includes cost per unit time, and specifies the time unit for the updated data. However, the units are not automatically translated when computing formula costs, so you need to make sure that you handle the time units correctly. For example, if you reported cost data in minutes but your formula produces CPU hours, you need to convert the time elements explicitly. To find out what units are used for the cloud cost data, you can query Budgets via `amgr ls clouddata`; see section 4.2.2.10, “Listing Cloud Data”, on page 90.

3.2.3.1.v Distinguishing Cloud Costs from On Premise Costs

Budgets has the following reserved words that you can use in formulas to indicate how cloud or on premise job costs should be calculated:

IS_CLOUD_JOB

Flag to indicate whether or not this calculation applies to a cloud job. Set internally by Budgets. Used by Budgets when applying this formula to a job. When job's am_job_cache resource contains *False*, Budgets sets this to *0*.

Values:

0: Job is not a cloud job

1: Job is a cloud job

Default: *0*

IS_ONPREMISE_JOB

Flag to indicate whether or not this calculation applies to an on premise job. Set internally by Budgets. Used by Budgets when applying this formula to a job. When job's am_job_cache resource contains *False*, Budgets sets this to *1*.

Values:

0: Job is not an on premise job

1: Job is an on premise job

Default: *1*

CLOUD_COST

Cloud cost per reported CPU. Set internally by Budgets, using cost information you provide to Budgets via `amgr update clouddata` (see section 4.2.3.10, “Updating Cloud Cost Data”, on page 98).

Default: *1*

3.2.3.2 Defining Service Units

In order to use a standard service unit, you must define it in the formula file. You define the formula for each service unit in the "formulas" section. Make sure that the name you use for the service unit in a formula is identical to the name you use in the `amgr add serviceunit` command. The service unit name should consist only of alphanumeric and underscore characters; blank spaces are not allowed.

You do not need to define dynamic service units in the formula file.

See section 1.7.2, “Service Units”, on page 18.

3.2.3.3 Defining Cloud and On Premise Service Units

You can calculate separate costs for cloud and on premise jobs by using the reserved words IS_CLOUD_JOB, IS_ONPREMISE_JOB, and CLOUD_COST. You can create formulas that handle both cloud and on premise jobs.

Use IS_CLOUD_JOB and IS_ONPREMISE_JOB as on-off switches to control whether a cost contributes to what is computed. When calculating cloud costs, include IS_CLOUD_JOB in each formula for cloud costs. When calculating on premise costs, include IS_ONPREMISE_JOB in each formula for on premise costs.

Budgets examines the value of the job's am_job_cache resource to see how the server resource am_cloud_enabled was set when the job was submitted. The value of the server resource is recorded in the job resource at the time of job submission.

When the recorded value for am_cloud_enabled is *True*, and this is a cloud job, Budgets treats this job as a cloud job, and sets IS_ONPREMISE_JOB to *0*, and sets IS_CLOUD_JOB to *1*, for this job.

When the recorded value for am_cloud_enabled is *False*, Budgets treats this job as on premise (whether or not it is a cloud job), and sets IS_ONPREMISE_JOB to *1*, and sets IS_CLOUD_JOB to *0*, for this job.

For cloud jobs, use CLOUD_COST as the cost per unit time for an instance. Budgets calculates the value of CLOUD_COST using the cloud cost data you provided via `amgr update clouddata`. When calculating the cost for a cloud job, Budgets uses the cost for the instance that the job would use.

3.2.3.3.i Example of Defining Cloud and On Premise Service Units

Example 3-3: Define the following service units:

- onpremise_cpu_hrs: number of CPU hours on premise
- cloud_cpu_hrs: number of CPU hours in the cloud
- onpremise_dollar: on premise CPU hours, multiplied by cost per unit time for those CPUs
- cloud_dollar: cloud CPU hours, multiplied by cost per unit time for those CPUs
- dollar: total cost for on premise and cloud jobs; on premise dollars plus cloud dollars

We also define CONST_onpremise_cpu_cost as the cost per unit time for on premise CPUs.

Formula file:

```
{
    "auth_user": "amteller",
    "constants":{
        "ncpus" : "job.ncpus",
        "walltime" : "job.walltime",
        "CONST_onpremise_cpu_cost" : 0.05
    },
    "formulas":{
        "onpremise_cpu_hrs" : "(ncpus*walltime)*IS_ONPREMISE_JOB",
        "cloud_cpu_hrs" : "(ncpus*walltime)*IS_CLOUD_JOB",
        "onpremise_dollar" : "(ncpus*walltime*CONST_onpremise_cpu_cost)*IS_ONPREMISE_JOB",
        "cloud_dollar" : "(ncpus*walltime*CLOUD_COST)*IS_CLOUD_JOB",
        "dollar" : "(ncpus*walltime*CONST_onpremise_cpu_cost*IS_ONPREMISE_JOB)
                    +(ncpus*walltime*CLOUD_COST*IS_CLOUD_JOB)"
    }
}
```

If we use the formulas in this example, and have a job with:

- ncpus = 2
- walltime = 10

Where

- CONST_onpremise_cost = 0.05
- CLOUD_COST = 0.1

Then, for an on premise job:

- IS_CLOUD_JOB = 0
- IS_ONPREMISE_JOB = 1
- onpremise_cpu_hrs = (2*10)*1 = 20
- cloud_cpu_hrs = (2*10)*0 = 0
- onpremise_dollar = (2*10*0.05)*1 = 1
- cloud_dollar = (2*10*0.1)*0 = 0
- dollar = (2*10*0.05)*1 + (2*10*0.1)*0 = 1+0 = 1

And for a cloud job:

- IS_CLOUD_JOB = 1
- IS_ONPREMISE_JOB = 0
- onpremise_cpu_hrs = (2*10)*0 = 0
- cloud_cpu_hrs = (2*10)*1 = 20
- onpremise_dollar = (2*10*0.05)*0 = 0
- cloud_dollar = (2*10*0.1)*1 = 2
- dollar = (2*10*0.05)*0 + (2*10*0.1)*1 = 0+2 = 2

3.2.3.4 Default Billing Formula File Contents

This is the contents of the default am_hook.json configuration file used by the Budgets hook. The default service unit is cpu_hrs.

```
{
    "auth_user" : "amteller",
    "constants":{
        "cpu_count": "job.ncpus",
        "time_span": "job.walltime"
    },
    "formulas":{
        "cpu_hrs": "cpu_count*time_span"
    }
}
```

3.2.3.5 Formula File Examples

Example 3-4: Configuration file using multiple constants and operators. We define the constants CONST_a, CONST_b, and CONST_prio. We use them in the formulas section with logical operators 'and', 'or', the comparison operator '>', and the arithmetic operator '*'.

```
{
    "auth_user" : "amteller",
    "constants":{
        "cpu_count": "job.ncpus",
        "time_span": "job.walltime",
        "gpu_count": "job.ngpus",
        "queue_priority": "queue.Priority",
        "node_cpus": "node.resources_available[ncpus]",
        "CONST_a": 2.0,
        "CONST_b": 1.0,
        "CONST_prio": 150
    },
    "formulas":{
        "cost":"(gpu_count and node_cpus or cpu_count)
            *time_span*(queue_priority > CONST_prio and CONST_a or CONST_b)"
    }
}
```

Example 3-5: Formula with three different service units called cpu_hrs, gpu_hrs, and mics_hrs:

```
{
    "auth_user" : "amteller",
    "constants":{
        "cpu_count" : "job.ncpus",
        "time_span" : "job.walltime",
        "gpu_count" : "job.ngpus",
        "mic_count" : "job.nmics"
    },
    "formulas":{
        "cpu_hrs" : "cpu_count*time_span",
        "gpu_hrs" : "gpu_count*time_span",
        "mics_hrs" : "mic_count*time_span"
    }
}
```

3.2.4 Create and Configure Budgets Hooks

1. Log into the PBS server host.
2. If the PBS server host is different from the Budgets server host, copy the hook and configuration files to the PBS server host.
3. Create and configure the am_hook and am_hook_periodic hooks:
   - For prepaid mode:

```
qmgr -c "c h am_hook"
qmgr -c "s h am_hook order=1000"
qmgr -c "i h am_hook application/x-python default  /opt/am/hooks/pbs/am_hook.py"
qmgr -c "i h am_hook application/x-config default /opt/am/hooks/pbs/<formula file>.json"
qmgr -c "s h am_hook enabled=true"
qmgr -c "s h am_hook alarm=90"
qmgr -c "c h am_hook_periodic"
qmgr -c "s h am_hook_periodic event=periodic"
qmgr -c "s h am_hook_periodic freq=120"
qmgr -c "i h am_hook_periodic application/x-python default  /opt/am/hooks/pbs/am_hook.py"
qmgr -c "i h am_hook_periodic application/x-config default /opt/am/hooks/pbs/<formula
    file>.json"
qmgr -c "s h am_hook_periodic enabled=true"
```

   - For prepaid mode when am_cloud_enabled = *False*:

```
qmgr -c "s h am_hook event='queuejob,runjob,modifyjob,movejob'"
```

   - For prepaid mode when am_cloud_enabled = *True*:

```
qmgr -c "s h am_hook event='queuejob,runjob,modifyjob,movejob,execjob_epilogue'"
```

   - For postpaid mode:

```
qmgr -c "c h am_hook"
qmgr -c "s h am_hook event='queuejob,modifyjob,movejob'"
qmgr -c "s h am_hook order=1000"
qmgr -c "i h am_hook application/x-python default  /opt/am/hooks/pbs/am_hook.py"
qmgr -c "i h am_hook application/x-config default /opt/am/hooks/pbs/<formula file>.json"
qmgr -c "s h am_hook enabled=true"
qmgr -c "s h am_hook alarm=90"
qmgr -c "c h am_hook_periodic"
qmgr -c "s h am_hook_periodic event=periodic"
qmgr -c "s h am_hook_periodic freq=120"
qmgr -c "i h am_hook_periodic application/x-python default  /opt/am/hooks/pbs/am_hook.py"
qmgr -c "i h am_hook_periodic application/x-config default /opt/am/hooks/pbs/<formula
    file>.json"
qmgr -c "s h am_hook_periodic enabled=true"
```

3.2.4.1 Caveats and Advice on Budgets Hooks

- Do not try to combine the Budgets hooks into one hook.
- The am_hook has to run after all the other hooks for each event. Make sure it has the highest order. For example, you can set it to a high order value such as 1000:

  ```
  qmgr -c "s h am_hook order=1000"
  ```
- The difference between postpaid and prepaid modes is that am_hook has a runjob event in prepaid mode but not in postpaid mode.

3.2.5 Configuring Resources for Budgets

3.2.5.1 List of PBS Professional Custom Resources for Budgets

Budgets uses the following custom resources:

am_cloud_enabled
: Boolean. Set at server. Value of this resource is recorded in each job's am_job_cache resource at the time of job submission.

  When you set this to *True*, add the execjob_epilogue event to the am_hook list of trigger events.

  Set by administrator.

am_job_amount
: String. Set by Budgets. Used for reporting costs.

am_job_cache
: String in JSON format. This resource is included in each job's resource request. Value of this string includes the value for the server am_cloud_enabled resource at the time of job submission. Set and used by Budgets.

am_job_quote
: Boolean. Set by job submitter. Indicates that Budgets should calculate cost estimate for a job and return that estimate to the job submitter. When this boolean is included in a job submission command, the job is not submitted.

am_finished_job
: String. Set by Budgets.

am_node_cache
: String. Set by Budgets.

3.2.5.2 Create and Set Resources

```
qmgr -c "c r am_cloud_enabled type=boolean"
qmgr -c "c r am_job_amount type=string"
qmgr -c "c r am_job_cache type=string,flag=m"
qmgr -c "c r am_job_quote type=boolean"
qmgr -c "c r am_finished_job type=string"
qmgr -c "c r am_node_cache type=string"
qmgr -c "set server resources_available.am_finished_job=NA"
```

3.2.6 Separating On Premise and Cloud Costs

You can use separate cost data and formulas for on premise and cloud jobs, or you can treat all jobs as if they are on premise jobs. This behavior is controlled by the value of the am_cloud_enabled server resource at the time each job is submitted. Budgets uses this resource as follows:

- When a job is submitted, the value of the am_cloud_enabled server resource is included in the data captured in the am_job_cache resource for that job
- When Budgets operates on a job, it uses the value of am_cloud_enabled stored in the job's am_job_cache resource to decide how to treat the job.
  - If the recorded value is *True*, and the job is a cloud job, costs for the job can be computed using cloud cost data, and formulas for cloud jobs are applied to this job
  - If the recorded value is *False*, the job is treated like an on premise job regardless of whether or not it is a cloud job. Costs for the job can be computed using on premise cost data, and formulas for on premise jobs are applied to this job

3.2.6.1 Behavior When Separating Costs in Prepaid Mode

Budgets examines the value of each job's am_job_cache resource, and acts accordingly.

When Budgets is in prepaid mode and a job's am_job_cache contains *True*:

- If the job is a cloud job, you can employ formulas specifically for cloud costs
  - Budgets automatically sets IS_CLOUD_JOB to *1* for this job
  - Budgets can use cloud cost data in formulas
- If the job is a cloud job, the job submitter can get a quote for this job using cloud cost data
- The job can run only when it has sufficient credit

When Budgets is in prepaid mode a job's am_job_cache contains *False*:

- Budgets behaves as if this is not a cloud job; this job is treated like an on premise job in formulas
  - Budgets sets IS_CLOUD_JOB to *0* for this job
  - Budgets sets IS_ONPREMISE_JOB to *1* for this job
- The job submitter can get a quote for this job using on premise data only
- The job can run only when it has sufficient credit

3.2.6.2 Behavior When Separating Costs in Postpaid Mode

When Budgets is in postpaid mode and a job's am_job_cache is *True*:

- You can employ formulas specifically for cloud costs
  - If this is a cloud job, Budgets automatically sets IS_CLOUD_JOB to *1* for this job
- The job submitter can get a quote for this job using cloud cost data
- The job can run regardless of credit

When Budgets is in postpaid mode and a job's am_job_cache is *False*:

- Budgets behaves as if this is not a cloud job; this job is treated like an on premise job in formulas
  - Budgets sets IS_CLOUD_JOB to *0* for this job
  - Budgets sets IS_ONPREMISE_JOB to *1* for this job
- The job submitter can get a quote for this job using on premise data only
- The job can run regardless of credit

3.2.6.3 Steps to Separate On Premise and Cloud Costs

To separate on premise and cloud costs:

- Set the am_cloud_enabled server-level Boolean resource to *True*:
  qmgr -c "set server resources_available.am_cloud_enabled=true"
- Add the execjob_epilogue trigger event to am_hook:
  qmgr -c "s h am_hook event='queuejob,runjob,modifyjob,movejob,execjob_epilogue'"

3.2.7 Requiring Sufficient Credit Before Bursting Cloud Nodes

You can require that job owners have sufficient credit before allowing cloud nodes to be burst for jobs, by setting the server's am_cloud_enabled resource to *True*. PBS Cloud examines the value of the server's am_cloud_enabled resource, and acts accordingly.

3.2.7.1 Behavior When Requiring Credit in Prepaid Mode

When Budgets is in prepaid mode and the server's am_cloud_enabled is *True* and a job's am_job_cache contains *True*, if this is a cloud job, PBS Cloud will burst nodes for this job only if it has sufficient credit, and that credit is calculated using cloud costs.

When Budgets is in prepaid mode and the server's am_cloud_enabled is *True* and a job's am_job_cache contains *False*, if this is a cloud job, PBS Cloud will burst nodes for this job only if it has sufficient credit, but that credit is calculated using on premise costs.

3.2.7.2 Behavior When Requiring Credit in Postpaid Mode

When Budgets is in postpaid mode, the value of the server's am_cloud_enabled is *True* does not affect the behavior of PBS Cloud. If this is a cloud job, PBS Cloud will burst nodes for this job when it is ready to run, regardless of credit.

3.2.8 Allow Easy Quote Request

We recommend making it easy for job submitters to get job quotes. Provide a wrapper for the quote request, and make it accessible to all job submitters. Add the following to /etc/bashrc (or the equivalent). The trailing space is important:

```
alias quote='qsub -l am_job_quote=true '
```

3.2.9 Changing the Billing Formula File

3.2.9.1 Procedure for Changing Billing Formula File

To change a formula you use at a PBS complex:

1. Drain all jobs from the PBS complex
2. Modify the formula
3. Update the complex and its cluster with the new formula file:

amgr update cluster -n <PBS server> -f <formula filename>

For example, to change the formula file for a PBS complex whose server is named HPC1, as well as its associated cluster, so that they use the formula defined in new_formula_hpc1.json:

```
amgr update cluster -n HPC1 -f new_formula_hpc1.json
```

See section 4.2.3.5, "Updating Clusters", on page 96

3.2.9.2 Caveats and Restrictions on Changing Billing Formula File

- Do not add resources to a formula while jobs are running. If you add new resources to a formula used by a PBS complex while jobs are running, any running jobs will fail to reconcile because they won't include the required data in their cache to allow Budgets to bill for the new resources.
- Do not change a formula while jobs are running. If you change a formula while jobs are running, users with running jobs may be billed for amounts that are different from the credit reservations made for those jobs, and different from what the users are expecting.
- Do not try to change a formula directly at the PBS complex, either by modifying the configuration file directly or by importing it. If the formula file for the Budgets hook is changed directly at the PBS complex, and not through the `amgr update` command, Budgets will throw an error.

3.3 Setting Budgets Configuration Attributes

Optionally, you can change the setting for the data_lifetime configuration attribute (it's not a parameter in the `am.conf` file; it's an attribute you set via `amgr update config`).

This attribute defines the maximum time allowed between updates to the value of a dynamic service unit. Budgets checks the update time for each dynamic service unit, for each project by calculating the value of (now - last update time for this dynamic service unit for this project).

If the value is not updated within the specified amount of time, Budgets logs a warning message in `/var/spool/am/<Budgets server hostname>.log`, but jobs can continue to run.

Format: integer seconds

Default: 3600

- To set the value of data_lifetime:

  amgr update config -n SU_DYNAMIC -V '{"data_lifetime":<new value>}'

  For example:

  ```
  amgr update config -n SU_DYNAMIC -V '{"data_lifetime":2400}'
  ```

  See section 4.2.3.8, "Updating Configuration Attributes", on page 97.

- To see the value of data_lifetime:

  ```
  amgr ls config   -n data_lifetime
  ```

  See section 4.2.2.8, "Listing Budgets Configuration Attributes", on page 88.

3.4 Configuring Budgets for Peer Scheduling

In a peer scheduling setup, different PBS complexes are set up to automatically run each others' jobs to dynamically load-balance jobs across the complexes. Budgets needs to be aware of all the PBS complexes in a peer scheduling environment.

To use Budgets when running jobs in multiple complexes in a peer scheduling environment:

1. Configure the Budgets hooks and its formula file at all of the PBS complexes involved in peer scheduling, and add one cluster to represent each PBS complex involved in peer scheduling to Budgets; see section 3.2, “Adding a PBS Complex and Setting its Billing Model”, on page 61.
2. Add the peer scheduling clusters to the project account or user account that will be running jobs, via `amgr update {user | project} -c <cluster>`; see section 4.2.3.3, “Updating Projects”, on page 93 and section 4.2.3.2, “Updating Users”, on page 93.

3.5 Changing Between Modes

3.5.1 Changing Mode from Postpaid to Prepaid

1. At each PBS complex, stop scheduling
2. Disable all PBS queues:

   ```
   qmgr -c 'set queue <queue name> enabled=false'
   ```
3. Allow all jobs to finish, or kill them
4. If necessary, reconcile all jobs:

   ```
   amgr reconcile [options]
   ```

   See section 4.3.6, “Reconciling Service Units”, on page 130
5. Stop Budgets:

   ```
   systemctl stop pbs_budget
   ```
6. Optionally make the balance zero for each account, period, and service unit
7. Change the AM_MODE configuration parameter in `am.conf` and set it to "prepaid"
8. Add the runjob hook event to am_hook:

   ```
   qmgr -c "set hook am_hook event += runjob"
   ```
9. Make sure that each account has sufficient credit to run their workload
10. Start Budgets

    ```
    systemctl start pbs_budget
    ```
11. Enable all PBS queues:

    ```
    qmgr -c 'set queue <queue name> enabled=true'
    ```
12. At each PBS complex, start scheduling

3.5.2 Changing Mode from Prepaid to Postpaid

1. At each PBS complex, stop scheduling
2. Disable all PBS queues:

   ```
   qmgr -c 'set queue <queue name> enabled=false'
   ```

3. Allow all jobs to finish, or kill them
4. If necessary, reconcile all jobs:

   ```
   amgr reconcile [options]
   ```

   See section 4.3.6, “Reconciling Service Units”, on page 130
5. Stop Budgets:

   ```
   systemctl stop pbs_budget
   ```

6. Optionally refund the balance for each account.
7. Change the AM_MODE configuration parameter in `am.conf` and set it to "postpaid"
8. Remove the runjob hook event from am_hook:

   ```
   qmgr -c "set hook am_hook event -= runjob"
   ```

9. Start Budgets

   ```
   systemctl start pbs_budget
   ```

10. Enable all PBS queues:

    ```
    qmgr -c 'set queue <queue name> enabled=true'
    ```

11. At each PBS complex, start scheduling

4
Budgets Commands

4.1 Budgets Commands

4.1.1 Command Path

To run Budgets commands, export the path of the `am` binaries to the PATH environment variable by using the command:

```
export PATH=$PATH:/opt/am/python/bin/
```

4.1.2 Using Budgets Commands

All Budgets commands are prefixed with "amgr ".

To see a list of Budgets subcommands with a single-line description for each command:

```
amgr <enter>
```

To get usage information for a command or subcommand:

<*command*> *--help*

<*command*> <*subcommand*> *--help*

For example:

`amgr add --help` provides information on how to use the main `amgr add` command

`amgr add period --help` provides information on how to use the `period` subcommand.

If you enter a command without the required arguments, Budgets will prompt you to enter them.

4.1.3 Tables of Budgets Commands

Table 4-1: Budgets Commands for Managing Elements

Function	Command	Element Subcommands	Required Privilege	Link
Adding elements	`amgr add`	`user, project, group, cluster, period, service-unit`	*admin*	Adding Elements
Listing elements	`amgr ls`	`user, project, group, cluster, period, service-unit, configuration, role, clouddata`	*user* can list periods, clusters, service units, own account, and roles, and all groups Member of project can list that project *manager* can list all elements *admin* can list cloud data	Listing Elements
Updating elements	`amgr update`	`user, project, group, cluster, period, service-unit, dynamicvalue, configuration, clouddata`	*admin*	Updating Elements
Removing elements	`amgr rm`	`user, project, group, cluster, period, service-unit`	*admin*	Removing Elements
Reporting elements	`amgr report`	`user, project, group, transaction`	*user* can get report on self and own jobs and transactions Project member can get report on that project *manager* or *investor* can get report on all groups and projects	Getting Reports on Elements
Applying limits to dynamic service units	`amgr limit`	`user, project`	Group *manager*	Applying Limits to Dynamic Service Units
Syncing formula file to cluster	`amgr sync`	`cluster`	*admin*	Syncing Formula File to PBS Complex

Table 4-2: Budgets Transaction and Account Checking Commands

Function	Command	Element Subcommands	Required Privilege	Link
Depositing service units	`amgr deposit`	`user, project, group`	*investor* for deposit to group Group *manager* for deposit to user or project account	Depositing Service Units
Checking balance of service units	`amgr check-balance`	`user, project, group`	*user* can check balance for self Project member can check balance for that project *manager* or *investor* can check balance for all groups and projects	Checking Service Unit Balance
Withdrawing service units	`amgr withdraw`	`user, project, group`	*investor* to withdraw from group Group *manager* to withdraw from user or project account	Withdrawing Service Units
Transferring service units	`amgr transfer`	`user, project, group`	*admin*	Transferring Service Units
Prechecking service unit balance	`amgr precheck`	`user, project, jobs`	*user* can precheck own balance *admin* or *teller* can check other balances	Prechecking Service Unit Balance
Acquiring service units	`amgr acquire`	`user, project`	*admin* or *teller*	Acquiring Service Units
Reconciling service units	`amgr reconcile`	`user, project`	*admin* or *teller*	Reconciling Service Units
Refunding service units	`amgr refund`	`transaction`	*admin*	Refunding Service Units

4.2 Commands for Managing Budgets Elements

You use these commands to add, remove, update, list, get reports on, apply limits to, and synchronize Budgets elements.

4.2.1 Adding Elements

amgr add {user | project | group | cluster | period | serviceunit}

4.2.1.1 Required Privilege

You must be *admin* to run this command.

4.2.1.2 Adding a User

4.2.1.2.i Synopsis

amgr add user -n <username> -A <accounting policy> -c <PBS server> -r <role> [-h <group list>] [-a <active>]

4.2.1.2.ii Description

Adds specified user to Budgets.

The specified user must already be a PBS complex user. Each user you add to Budgets should have an entry in the password file, with a password set, and a home directory on the Linux system where Budgets is installed.

When you add a user, you must assign a role, a cluster, and an accounting policy to that user.

4.2.1.2.iii Options

-n, --name <username>

String. Username to add.

The username and project name cannot be the same.

-A, --accounting-policy <accounting policy>

String. Specifies the accounting policy for the user account. Required.

Valid values: *begin_period* | *end_period* | *proportionate*

- A project with the begin_period accounting policy is charged in the period when the job begins.
- A project with the end_period accounting policy is charged in the period when the job ends.
- A project with the proportionate accounting policy is charged during the periods when the jobs were run. Each period is charged in proportion to the use in that period.

See section 1.7.4, “Accounting Policy”, on page 23.

-c, --clusters <PBS server>

String. Associates the user with the specified cluster. Required.

Use the `-c <PBS server>` option once for each cluster.

-r, --role <admin | investor | manager | teller | user>

String. Sets the role of the user. Required.

-h, --groups <group>

String. Associates the user account with specified groups.

Use the `-h <group>` option once for each group.

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}

Boolean. Activates or deactivates the user account.

Default: *True*, user account is active

4.2.1.2.iv Command Examples

Example 4-1: Add a user named "joe", setting the accounting policy to "begin_period", associating joe with cluster1 and group group01, and giving joe the role of *user*:

```
amgr add user -n joe -A begin_period -c cluster1 -r user -h group01
```

Example 4-2: Add a user to Budgets, then add them to group01 as a *manager*:

```
amgr add user -n user01 -A begin_period -c user1 -r manager -h group01
amgr update group -n group01 -M + user01
```

Example 4-3: Add user user1 to Budgets and add them to groups group01 and engineering as an *admin*, giving them the begin_period accounting policy, and adding them to the testbed1 and testbed2 PBS complexes:

```
amgr add user -n user1 -A begin_period -h group1 -h engineering -c testbed1 -c testbed2 -r admin
```

4.2.1.3 Adding a Project

4.2.1.3.i Synopsis

amgr add project -n <project name> -A <accounting policy> [-S <start date>] [-E <end date>] -c <PBS server> [-u <user>] [-h <group>] [-a <active>] [-m <metadata>]

4.2.1.3.ii Description

Adds specified project to Budgets.

4.2.1.3.iii Options

-n, --name <project name>

String. Name of project to add.

The project name cannot be the same as a username.

-A, --accounting-policy <accounting policy>

String. Specifies the accounting policy for the project account. Required.

Valid values: *begin_period* | *end_period* | *proportionate*

- A project with the begin_period accounting policy is charged in the period when the job begins.
- A project with the end_period accounting policy is charged in the period when the job ends.
- A project with the proportionate accounting policy is charged during the periods when the jobs were run. Each period is charged in proportion to the use in that period.

See section 1.7.4, “Accounting Policy”, on page 23.

-S, --start-date <start date>

Date. Start date of the project. Optional.

Format: YYYY-MM-DD

-E, --end-date <end date>

Date. End date of the project. Optional.

Format: YYYY-MM-DD

-c, --clusters <PBS server>

String. Associates the specified cluster with the project account.

Use the `-c <PBS server>` option once for each cluster. To add multiple clusters:

-c <cluster1> -c <cluster2> ... -c <clusterN>

-u, --users <username>

String. Associates the specified user with the project account.

Use the `-u <username>` option once for each user. To add multiple users:

-u <user1> -u <user2> ... -u <userN>

-h, --groups <group name>

String. Associates the specified group with the project.

Use the `-h <group name>` option once for each group. To add multiple groups:

-h <group1> -h <group2> ... -h <groupN>

-a, --active <True|TRUE|true|t|1|False|FALSE|false|f|0>

Boolean. Sets the project to active or inactive.

-m, --metadata <metadata>

String. Modifies metadata attribute for the project.

Format: comma-separated key-value pairs

Syntax:

<key1>:<value1>,<key2>:<value2>...<keyN>:<valueN>

Keys are undefined.

4.2.1.3.iv Example

Example 4-4: Add a project named proj1 and give it metadata consisting of type:weather and region:asia:

```
amgr add project -n proj1 -A begin_period -S 2022-01-02 -E 2022-28-02 -c cluster1 -m
    type:weather,region:asia
```

4.2.1.4 Adding a Group

4.2.1.4.i Synopsis

amgr add group -n <group name> [-I <investor>] [-M <manager>] [-a <active>]

4.2.1.4.ii Description

Define a group and add it to Budgets.

4.2.1.4.iii Options

-n, --name <group name>

String. Group to add.

-I, --investors <investor username>

String. Associates this investor with the specified group.

This username must already exist in Budgets and have the *investor* or *admin* role.

You can associate one investor per `-I` option, and you can associate multiple investors per command line. To associate multiple investors:

-I <investor1> -I <investor2> ... -I <investorN>

-M, --managers <manager username>

String. Associates this manager with the specified group.

This username must already exist in Budgets and have the *manager*, *investor*, or *admin* role.

You can associate one manager per -M option, and you can associate multiple managers per command line. To associate multiple managers:

-M <manager1> -M <manager2> ... -M <managerN>

Group managers can transfer funds from the group to projects and user accounts.

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}

Boolean. Sets the group active or inactive.

Default: active

4.2.1.5 Adding a Cluster

4.2.1.5.i Synopsis

amgr add cluster -n <PBS server> [-f <billing formula filename>] [-a <active>]

4.2.1.5.ii Description

Adds a cluster data structure to represent the specified PBS complex.

You can specify the billing formulas used for each cluster at the time you add the cluster, or later; although if the formula file at the cluster does not match the formula file at the complex, jobs cannot run at that complex. When you specify the billing formulas, this updates the cluster data structure with the formulas.

You can set the cluster to active or inactive.

You can add multiple PBS complexes, but only one per command line.

4.2.1.5.iii Options

-n, --name <PBS server>

String. Name of the PBS server for the PBS complex.

-f, --formula <formula filename>

Sets the formula file at the cluster. Make sure these are the same formulas as the ones at the complex.

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}

Boolean. Sets cluster active or inactive. When the cluster is active, it can run jobs.

Default: active

4.2.1.6 Adding a Period

4.2.1.6.i Synopsis

amgr add period -n <period name> -S <start date> -E <end date> [-p <name of parent period>]

4.2.1.6.ii Description

Adds the specified period.

Make sure that periods at the same level do not overlap. For example, if Quarter1 ends March 31st, make sure that Quarter2 does not begin sooner than April 1st.

If you want to create periods with a parent-child relationship, you must create the parent period first. You cannot add a parent to an existing child. For example, if you want Year as the parent and Quarter1, Quarter2, etc., as children, create Year first.

If you create child periods, make sure that they fit within the parent period.

Make sure that your period hierarchy is finalized BEFORE doing any transactions or running any jobs; you cannot update or remove periods once transactions have been performed or jobs have started.

See section 1.7.1, "Periods, Allocation Periods, Billing Periods", on page 18.

4.2.1.6.iii Options

-n, --name <period name>

String. Period to add.

-S, --start-date <start date>

Date. Start date of the period.

Format: YYYY-MM-DD

-E, --end-date <end date>

Date. End date of the period.

Format: YYYY-MM-DD

-p, --parent <name of parent period>

String. Specifies the parent period. Optional.

4.2.1.7 Adding a Service Unit

4.2.1.7.i Synopsis

amgr add serviceunit -n <service unit name> [-t <type>] [-a <active>] [-d <description>]

4.2.1.7.ii Description

Adds a service unit to Budgets. This service unit is defined in the formula file.

Add a standard service unit to measure consumption of a resource internally tracked by PBS, for example CPU hours.

Add a dynamic service unit to define a quota for an external resource.

Default type is standard service unit (SU_STANDARD).

4.2.1.7.iii Options

-n, --name <service unit name>

String. Name of service unit to add. If this is a standard service unit, name must match name used in formula file.

Blank spaces are not allowed.

-t, --type {SU_STANDARD | SU_DYNAMIC}

String. Specifies type for this service unit.

Default: *SU_STANDARD*

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}

Boolean. Sets service unit active or inactive.

-d, --description <service unit description>

String. Describes the service unit.

Can contain alphanumeric and any special characters except double quotes.

If the description contains anything except alphanumeric, enclose it in double quotes.

4.2.1.7.iv Command Examples

Example 4-5: Adding a standard service unit named cpu_hrs to be used for CPU hours:

```
amgr add serviceunit -n cpu_hrs -d "CPU hours"
```

Example 4-6: Adding a dynamic service unit named luster:

```
amgr add serviceunit -n luster -t SU_DYNAMIC
```

4.2.2 Listing Elements

amgr ls {user | period | project | cluster | serviceunit | role | clouddata}

Prints out Budgets elements. You can list only elements that have already been added to Budgets via `amgr add` or `amgr update`.

By default, this command lists only active elements. To list active elements:

```
amgr ls
```

To list inactive elements, use the `-a False` option. For example, to list all the clusters which are inactive:

```
amgr ls cluster -a False
```

Use the `-l` switch for `amgr ls` commands for more detailed information.

Use the `-j` switch for `amgr ls` commands to get the detailed information output in JSON format. This output can be used by other programs which can process JSON format.

4.2.2.1 Required Privilege

A *user* can list periods, clusters, service units, own account, own projects, own role, and all groups.

A member of a project can list that project.

A *manager* can list all elements.

4.2.2.2 Listing Users

4.2.2.2.i Synopsis

amgr ls user [-n <username] [-a <active>] [-h <group name>] [-l | -j] [-r <role>]

4.2.2.2.ii Description

When used with no options, lists all the users that exist in Budgets. When you specify a username, prints information about that user.

4.2.2.2.iii Options

-n, --name <username>

String. Specifies the name of the user.

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}

Boolean. Filters users by active status. You can list either active or inactive users, but not both.

Default: active

-h, --group <group name>

String. Lists all users in specified group.

-l, --list-info

Display information in list format.

-j, --json-info

Display information in JSON format.

-r, --role <role>

String. Lists all users with specified role.

4.2.2.3 Listing Projects

4.2.2.3.i Synopsis

amgr ls project [-n <project name] [-a <active>] [-h <group name>] [-l | -j] [-u <username>]

4.2.2.3.ii Description

When used with no options, lists all the projects that exist in Budgets. When you specify a project name, prints information about that project.

4.2.2.3.iii Options

-n, --name <project name>

String. Specifies the name of the project.

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}

Boolean. Filters projects by active status. You can list either active or inactive projects, but not both.

Default: active

-h, --group <group name>

String. Lists all projects associated with specified group.

-l, --list-info

Display information in list format.

-j, --json-info

Display information in JSON format.

-u, --user <username>

String. Lists all projects with which specified user is associated.

4.2.2.4 Listing Groups

4.2.2.4.i Synopsis

amgr ls group [-n <group name>] [-a <active>] [-I <investor name>] [-l | -j] [-M <manager name>]

4.2.2.4.ii Description

When used with no options, lists all the groups that exist in Budgets. When you specify a group name, prints information about that group.

4.2.2.4.iii Options

-n, --name <group name>

String. Specifies the name of the group.

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}

Boolean. Filters groups by active status. You can list either active or inactive groups, but not both.

Default: active

-I, --investor <investor name>

String. Lists all groups associated with specified investor.

-j, --json-info

Display information in JSON format.

-l, --list-info

Display information in list format.

-M, --manager <manager name>

String. Lists all groups associated with specified manager.

4.2.2.5 Listing Clusters

4.2.2.5.i Synopsis

amgr ls cluster [-n <PBS server>] [-a <active>] [-f] [-l | -j]

4.2.2.5.ii Description

By default, lists all active clusters. You can specify whether you want to see active or inactive clusters. To display inactive clusters:

```
amgr ls cluster -a False
```

4.2.2.5.iii Options

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}

Boolean. Filters clusters by active status. You can list either active or inactive clusters, but not both.

Default: active

-n, --name <PBS server>

String. Name of the cluster to list.

You can list one cluster per command line.

-f, --formula

Prints formula file to `/tmp`, and prints the path to that file on screen.

-l, --list-info

Display information in list format.

-j, --json-info

Display information in JSON format.

4.2.2.5.iv Examples

Example 4-7: To print the formula file for cluster1:

```
amgr ls cluster -n cluster1 -f
```

Output formula file: `/tmp/cluster1_formula.json`

4.2.2.6 Listing Periods

4.2.2.6.i Synopsis

amgr ls period [-n <period>] [-l | -j]

4.2.2.6.ii Description

Prints out information about periods.

By default, this lists all periods that exist in the hierarchy.

See section 1.7.1, “Periods, Allocation Periods, Billing Periods”, on page 18.

4.2.2.6.iii Options

-n, --name <period name>
: String. Name of the period to list.

-l, --list-info
: Display information in list format.

-j, --json-info
: Display information in JSON format.

4.2.2.7 Listing Service Units

4.2.2.7.i Synopsis

amgr ls serviceunit [-n <service unit name] [-a <active>] [-l | -j]

4.2.2.7.ii Description

When used with no options, lists all the service units that exist in Budgets. When you specify a service unit name, prints information about that service unit.

4.2.2.7.iii Options

-n, --name <service unit name>
: String. Specifies the name of the service unit.

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}
: Boolean. Filters service units by active status. You can list either active or inactive service units, but not both.

Default: active

-l, --list-info
: Display information in list format.

-j, --json-info
: Display information in JSON format.

4.2.2.8 Listing Budgets Configuration Attributes

4.2.2.8.i Synopsis

amgr ls config [-n <attribute name>] [-l | -j]

4.2.2.8.ii Description

Prints a list of the Budgets configuration attributes. See section 3.3, “Setting Budgets Configuration Attributes”, on page 73.

4.2.2.8.iii Options

-n, --name <attribute name>
: String. Specifies the name of the configuration attribute.

-l, --list-info
: Display information in list format.

-j, --json-info
: Display information in JSON format.

4.2.2.8.iv Sample Output

Sample output for `amgr ls config`:

```
SU_DYNAMIC
configuration = {'data_lifetime': 3600}
id = 1
created_user_name = root
created_date = 2022-05-12 09:42:53.312722+05:30
last_updated_user_name = root
last_updated_date = 2022-05-14 15:55:54.339+05:30
```

4.2.2.9 Listing Roles

4.2.2.9.i Synopsis

amgr ls role [-n <role>] [-a <active>] [-l | -j]

4.2.2.9.ii Description

Prints whether the role exists.

Every user in Budgets must have an assigned role. See section 1.4, “Roles”, on page 7.

Roles in Budgets:

admin
: Can perform all operations.

investor
: Can deposit and withdraw service units to and from groups with which the investor is associated.

manager
: Can deposit and withdraw service units to and from projects and users that are associated with groups with which the manager is associated.

teller
: Special role for performing automated acquire and reconcile transactions on behalf of users.

user
: Assigned to one or more projects; can run jobs using user budget or project budget.

4.2.2.9.iii Options

-n, --name <role>

String. Name of the role to list.

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}

Boolean. Filters roles by active status. You can list either active or inactive roles, but not both.

Default: active

-l, --list-info

Display information in list format. Information includes whether the role is active for each user with the role.

-j, --json-info

Display information in JSON format.

4.2.2.9.iv Command Example

Example 4-8: To show information for users with *admin* role:

```
amgr ls role -n admin
```

Example 4-9: To show more information about users with *admin* role, we use the -l switch:

```
amgr ls role -n admin -l
```

Example 4-10: To show information about users with *admin* role in JSON format, we use the -j switch:

```
amgr ls role -n admin -j
```

4.2.2.10 Listing Cloud Data

4.2.2.10.i Synopsis

amgr ls clouddata [-n <cloud account name] [-t <instance type>] [-l | -j]

4.2.2.10.ii Description

To see a list of all cloud accounts and instance types, but not cost data, use no options.

To see a list of all cloud accounts and instance types, along with instance type costs, use either the `-l` or `-j` options, and use neither the `-n` nor the `-t` options.

To see a list of instance types associated with a cloud account, use the `-n` option to specify that account.

To see a list of cloud accounts associated with an instance type, use the `-t` option to specify that instance type.

4.2.2.10.iii Options

-n, --account-name <cloud account name>

String. Specifies the name of the cloud account.

Lists the instance types associated with this cloud account.

-t, --instance-type <instance type>

String. Specifies the instance type.

Lists the cloud accounts associated with this instance type.

(neither -n nor -t)

With `-l` option: lists all cloud accounts and associated instance types, along with cost information.

With `-j` option: prints all cloud accounts and associated instance types, along with cost information, in JSON format.

With neither the `-l` or `-j` options, lists all cloud accounts and associated instance types, without cost information.

-l, --list-info

Displays information in list format.

-j, --json-info

Displays information in JSON format.

4.2.2.10.iv Examples

Example 4-11: List all cloud accounts and their associated instance types:

```
amgr ls clouddata
xyz-aws:c4.large
xyz-azure:t2.micro
```

Example 4-12: List the instance types associated with a specific cloud account:

```
amgr ls clouddata -n xyz-aws
xyz-aws:c4.large
```

Example 4-13: List the cloud accounts associated with a specific instance type:

```
amgr ls clouddata -t t2.micro
xyz-azure:t2.micro
```

Example 4-14: Validate that a particular cloud account is associated with a particular instance type:

```
amgr ls clouddata -n xyz-aws -t c4.large
xyz-aws:c4.large
```

Example 4-15: List all cloud accounts and associated instance types along with cost information for each instance type:

```
amgr ls clouddata -l
xyz-aws
    instance_type = c4.large
    cost_info = {'cost': 100, 'ncpus': 20, 'overhead': 40, 'unit': 'hour'}
    metadata = {'provider': 'aws', 'scenario': 'xyz-aws-poc'}
    id = 2
    created_user_name = root
    created_date = 2022-05-18 17:33:00.310976+05:30
    last_updated_user_name = root
    last_updated_date = 2022-05-18 17:33:00.310976+05:30

xyz-azure
    instance_type = t2.micro
    cost_info = {'cost': 80, 'ncpus': 10, 'overhead': 20, 'unit': 'hour'}
    metadata = {'provider': 'azure', 'scenario': 'xyz-azure-poc'}
    id = 3
    created_user_name = root
    created_date = 2022-05-18 17:33:00.310976+05:30
    last_updated_user_name = root
    last_updated_date = 2022-05-18 17:33:00.310976+05:30
```

4.2.3 Updating Elements

amgr update {user | period | project | group | cluster | serviceunit | clouddata}

Updates the specified element.

You cannot change the name of an element once it is created.

4.2.3.1 Required Privilege

You must be *admin* to run this command.

4.2.3.2 Updating Users

4.2.3.2.i Synopsis

amgr update user -n <username> [-A <accounting policy>] [-c <cluster list>] [-r <roles>] [-h <group list>] [-a <active>]

4.2.3.2.ii Description

Update information for a user.

4.2.3.2.iii Options

-n, --name <username>

String. Name of user account to update.

-A, --accounting-policy <begin_period | end_period | proportionate>

Specifies the accounting policy for the user account. It can be begin_period, end-period, or proportionate

-c, --clusters <cluster update>

String. Specifies clusters to link to or unlink from the user.

To link or unlink clusters, use the + or - operator followed by a comma-separated list of clusters. Spaces are not allowed. Use a separate `amgr update user -n <username> -c <cluster update>` command for each + or - operation.

For example, to link clusters:

```
amgr update user -n user1 -c + cluster1,cluster2,cluster3
```

Or to unlink clusters:

```
amgr update user -n user1 -c - cluster4,cluster5,cluster6
```

-r, --roles <role>

Sets the role of the user.

-h, --groups <group update>

String. Specifies groups to link to or unlink from the user.

To link or unlink groups, use the + or - operator followed by a comma-separated list of groups. Spaces are not allowed. Use a separate `amgr update user -n <username> -h <group update>` command for each + or - operation.

For example, to link groups:

```
amgr update user -n user1 -h + group1,group2,group3
```

Or to unlink groups:

```
amgr update user -n user1 -h - group4,group5,group6
```

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}

Set the project to active or inactive.

4.2.3.3 Updating Projects

4.2.3.3.i Synopsis

amgr update project -n <project name> [-A <accounting policy>] [-S <start date>] [-E <end date>] [-c <cluster update>] [-u <user update>] [-h <group update>] [-a <active>] [-m <metadata update>]

4.2.3.3.ii Description

Updates project information. You can set new values for existing elements, add new elements such as users, groups, or metadata, and you can remove elements. Use the + operator to add or update elements and the - operator to remove elements.

4.2.3.3.iii Options

-n, --name <project name>

String. Name of the project to update.

-A, --accounting-policy <accounting policy>

String. Specifies the accounting policy for the project.

Value is one of *begin_period*, *end_period,* or *proportionate*.

-S, --start-date <start date>

Start date of the project.

Format: YYYY-MM-DD

-E, --end-date <end date>

End date of the project.

Format: YYYY-MM-DD

-c, --clusters <cluster update>

String. Specifies clusters to link to or unlink from the project.

To link or unlink clusters, use the + or - operator followed by a comma-separated list of clusters. Spaces are not allowed. Use a separate `amgr update project -n <project name> -c <cluster update>` command for each + or - operation.

For example, to link clusters:

```
amgr update project -n MyProject -c + cluster1,cluster2,cluster3
```

Or to unlink clusters:

```
amgr update project -n MyProject -c - cluster4,cluster5,cluster6
```

-u, --users <user update>

String. Specifies users to link to or unlink from the project.

To link or unlink users, use the + or - operator followed by a comma-separated list of users. Spaces are not allowed. Use a separate `amgr update project -n <project name> -u <user update>` command for each + or - operation.

For example, to link users:

```
amgr update project -n MyProject -u + user1,user2,user3
```

Or to unlink users:

```
amgr update project -n MyProject -u - user4,user5,user6
```

-h, --groups <group update>

String. Specifies groups to link to or unlink from the project.

To link or unlink groups, use the + or - operator followed by a comma-separated list of groups. Spaces are not allowed. Use a separate `amgr update project -n <project name> -h <group update>` command for each + or - operation.

For example, to link groups:

```
amgr update project -n MyProject -h + group1,group2,group3
```

Or to unlink groups:

```
amgr update project -n MyProject -h - group4,group5,group6
```

-m, --metadata <metadata update>

Adds, updates, or removes metadata from the project.

To add metadata: + operator followed by a comma-separated list of key-value pairs. Spaces are not allowed. For example:

```
amgr update project -n MyProject -m + <key1>:<value>,<key2>:<value2>
```

To remove metadata: - operator followed by a comma-separated list of keys only. Spaces are not allowed. For example:

```
amgr update project -n MyProject -m - <key3>,<key4>
```

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}

Sets the project to active or inactive.

4.2.3.3.iv Command Example

Add a new metadata element named "currency", set it to "rupee", and update the existing data region to "america":

```
amgr update project -n proj1 -m + currency:rupee,region:america
```

Remove existing metadata elements "type" and "region":

```
amgr update project -n proj1 -m - type,region
```

Multiple operations in single command:

```
amgr update project -n proj1 -m + currency:dollar,"Lead Researcher":"Jane Smith" -m - type,region
```

4.2.3.4 Updating Groups

4.2.3.4.i Synopsis

amgr update group -n <group name> [-I <investors>] [-M <managers>] [-a <active>]

4.2.3.4.ii Description

Update information for a group.

4.2.3.4.iii Options

-n, --name <group name>

String. Name of the group to update.

-I, --investors <investor update>

String. Specifies investors to link to or unlink from the user.

To link or unlink investors, use the + or - operator followed by a comma-separated list of investors. Spaces are not allowed. Use a separate `amgr update group -n <group name> -I <investor update>` command for each + or - operation.

For example, to link investors:

```
amgr update group -n group1 -I + investor1,investor2,investor3
```

Or to unlink investors:

```
amgr update group -n group1 -I - investor4,investor5,investor6
```

-M, --managers <manager update>

String. Specifies managers to link to or unlink from the user.

To link or unlink managers, use the + or - operator followed by a comma-separated list of managers. Spaces are not allowed. Use a separate `amgr update group -n <group name> -M <manager update>` command for each + or - operation.

For example, to link managers:

```
amgr update group -n group1 -M + manager1,manager2,manager3
```

Or to unlink managers:

```
amgr update group -n group1 -M - manager4,manager5,manager6
```

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}

Sets the group to be active or inactive.

4.2.3.5 Updating Clusters

4.2.3.5.i Synopsis

amgr update cluster -n <PBS server> [-a <active>] [-f <formula filename>]

4.2.3.5.ii Description

Updates the cluster data structure representing a PBS complex with the specified formula file. Pushes the formula file to the PBS complex. Imports the formula file (the Budgets hook configuration file) into both Budgets hooks at the complex. Updates the database with the new formulas for this cluster.

If the formulas are different in the PBS hook (the .CF file) and the cluster data structure, jobs cannot run.

4.2.3.5.iii Options

-n, --name <PBS server>

String. Name of the cluster to update.

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}

Boolean. Sets the cluster active or inactive.

Default: active

-f, --formula <formula filename>

String. Updates the specified formula file at the specified cluster data structure.

4.2.3.6 Updating a Period

4.2.3.6.i Synopsis

amgr update period -n <period name> [-S <start date>] [-E <end date>]

4.2.3.6.ii Description

Updates the specified period.

You cannot update a period that has any associated jobs or transactions.

See section 1.7.1, “Periods, Allocation Periods, Billing Periods”, on page 18.

4.2.3.6.iii Options

-n, --name <period name>

String. Period to update.

-S, --start-date <start date>

Date. Start date of the period.

Format: YYYY-MM-DD

-E, --end-date <end date>

Date. End date of the period.

Format: YYYY-MM-DD

4.2.3.7 Updating a Service Unit

4.2.3.7.i Synopsis

amgr update serviceunit -n <service unit name> [-t <type>] [-a <active>] [-d <description>]

4.2.3.7.ii Description

Updates a service unit.

You can change the type of a service unit, but there are restrictions:

- You can change standard to dynamic only when no transactions have taken place
- You can change dynamic to standard only when no updates have been made to the external dynamicvalue

4.2.3.7.iii Options

-n, --name <service unit name>

String. Name of service unit to update.

Blank spaces are not allowed.

-t, --type {SU_STANDARD | SU_DYNAMIC}

String. Specifies type for this service unit.

Default: *SU_STANDARD*

-a, --active {True|TRUE|true|t|1|False|FALSE|false|f|0}

Boolean. Sets service unit active or inactive.

-d, --description <service unit description>

String. Describes the service unit.

Can contain alphanumeric and any special characters except double quotes.

If the description contains anything except alphanumeric, enclose it in double quotes.

4.2.3.8 Updating Configuration Attributes

4.2.3.8.i Synopsis

amgr update config -n <attribute name> -V <update string>

4.2.3.8.ii Description

Update Budgets configuration attributes. See section 3.3, “Setting Budgets Configuration Attributes”, on page 73.

Updates one attribute at a time.

4.2.3.8.iii Options

-n, --name <attribute name>

String. Name of the Budgets configuration attribute to update.

-V, --config-value <update string>

JSON formatted string of configuration key-value pairs.

Format:

amgr update config -n SU_DYNAMIC -V '{"<attribute name>": <value>}'

Example:

```
amgr update config -n SU_DYNAMIC -V '{"data_lifetime": 1000}'
```

4.2.3.8.iv Examples

```
amgr update config -n SU_DYNAMIC -V '{"data_lifetime": 3610}'
```

4.2.3.9 Updating Dynamic Service Unit Usage

4.2.3.9.i Synopsis

amgr update dynamicvalues -v <update specification>

4.2.3.9.ii Description

Reports updated value of the specified dynamic service unit to Budgets. Value is for usage by a project or a user.

At a given point in time, a dynamic service unit is a snapshot of the current usage of a particular external resource such as scratch. This usage is reported by an external script that you write. The external script is typically a `cron` job that calls `amgr update dynamicvalues`, which updates the value of the dynamic service unit.

Budgets compares the reported value with the specified quotas, and allows jobs to run as long as the usage is below the quota.

4.2.3.9.iii Required Privilege

You must be *admin* to run this command.

4.2.3.9.iv Options

-v, --value <update specification>

String in JSON format.

Format to update usage for a user:

'{"<dynamic service unit>": {"<username>":{"total":<total>}}}'

Format to update total usage for a project:

'{"<dynamic service unit>": {"<project>":{"total":<total>}}}'

You must include the keyword "total".

4.2.3.9.v Examples

Example 4-16: Set user user1's consumption of storage to 8:

```
amgr update dynamicvalues -v '{"storage": {"user1": {"total":8}}}'
```

Example 4-17: Set project project1's consumption of storage to 30:

```
amgr update dynamicvalues -v '{"storage": {"project1": {"total":30}}}'
```

4.2.3.10 Updating Cloud Cost Data

4.2.3.10.i Synopsis

amgr update clouddata [-v <update specification> | -J <input file>]

4.2.3.10.ii Description

Updates Budgets with cloud cost data for specified accounts and instances. The administrator gets the cloud cost data from the vendor, then uses this command to update Budgets. The command transmits the updated cost information via either a JSON string or a JSON file.

Budgets uses these costs when computing service unit charges.

The cost to use an instance type depends on service provider charges, which may vary according to the instance type. Spot instances may vary more often than others.

This command is intended to be used in a `cron` job or a periodic hook.

4.2.3.10.iii Required Privilege

You must be *admin* to run this command.

4.2.3.10.iv Options

-v, --value <update specification>

String in JSON format. You populate this string with data collected from service provider(s). Format:

```
'{
    "<cloud account 1>":{
        "<instance type 1>":{
            "cost_info":{
                "cost":<cost per unit time>,
                "ncpus":<CPUs in one instance>,
                "overhead":<cost for overhead>,
                "unit":<unit of time>
            },
            "metadata":{
                "key1":"value1",
                "key2":"value2",
                ...
            }
        }
    },
    "<cloud_account2>":{
        "<instance_type2>":{...}
    },
    ...
}'
```

Cost information section contains the following:

cost
: Float. Instance cost per unit of time.

ncpus
: Integer. Total number of CPUs available inside one instance.

overhead
: Float. Total overhead cost for one instance.

unit
: String. Unit of time for the *cost* and *overhead* values.

Allowed values: *hour* | *minute* | *second*

Metadata section is key-value pairs containing metadata for the instance.

Format:

"<key>":"<value>","<key>":"<value>", ...

Maximum of 10 pairs allowed.

Cannot be used with `-J` option.

-J, --json-file <path to input file>

String. Path to input file containing cost data. Can be absolute or relative to directory where command is run.

Format: same as JSON string argument to `-v <update specification>` option.

Cannot be used with `-v` option.

--help

Prints usage information and exits.

4.2.3.10.v Examples

Example 4-18: Update cloud cost data for the cloud account named "CloudAccount1" and the instance type "Standard_D2s_v3". We show how to update using a JSON string or an input file:

Update via JSON string:

```
amgr update clouddata -v
    '{"CloudAccount1":{"Standard_D2s_v3":{"cost_info":{"cost":0.105,"ncpus":2,"overhead":0.02,"u
    nit":"hour"},"metadata":{"provider":"azure","scenario":"azureScenario1"}}}}'
```

Update via input file:

```
amgr update clouddata -J /tmp/my_cloud_cost_data.json
```

Where:

```
cat /tmp/my_cloud_cost_data.json
{
    "CloudAccount1":{
        "Standard_D2s_v3":{
            "cost_info":{
                "cost":0.105,"ncpus":2,"overhead":0.02,"unit":"hour"
            },
            "metadata":{
                "provider":"azure","scenario":"azureScenario1"
            }
        }
    }
}
```

Example 4-19: Update cloud cost data for two separate cloud accounts, using a file:

```
amgr update clouddata -J /tmp/cloud_cost_data.json
```

Where:

```
cat /tmp/cloud_data.json
{
    "CloudAccount1":{
        "Standard_D2s_v3":{
            "cost_info":{"cost":0.105,"ncpus":2,"overhead":0.02,"unit":"hour"},
            "metadata":{"provider":"azure","scenario":"azureScenario"}
        }
    }
    "CloudAccount2":{
        "Standard_D2s_v4":{
            "cost_info":{"cost":0.205,"ncpus":2,"overhead":0.05,"unit":"hour"}
        }
    }
}
```

4.2.3.10.vi Caveats for Updating Cloud Cost Data

Keep in mind that the units you report to Budgets using this command will affect how you use units in the formula file. In the formula file, Budgets assumes that cost units are in seconds.

4.2.4 Removing Elements

amgr rm {user | project | group | cluster | period | serviceunit}

4.2.4.1 Required Privilege

You must be *admin* to run this command.

4.2.4.2 Removing a User

4.2.4.2.i Synopsis

amgr rm user -n <username>

4.2.4.2.ii Description

Removes specified user from Budgets, unless the user has any past or current associated jobs or transactions, in which case the user is made inactive.

4.2.4.2.iii Options

-n, --name <username>

String. Name of the user to remove.

4.2.4.2.iv Command Examples

Example 4-20: Remove a user named "joe":

```
amgr rm user -n joe
```

4.2.4.3 Removing a Project

4.2.4.3.i Synopsis

amgr rm project -n <project name>

4.2.4.3.ii Description

Removes specified project from Budgets, unless the project has any past or current associated jobs or transactions, in which case the project is made inactive.

4.2.4.3.iii Options

-n, --name <project name>

String. Name of the project to remove.

The project name cannot be the same as a username.

4.2.4.3.iv Example

Example 4-21: Remove a project named proj1:

```
amgr rm project -n proj1
```

4.2.4.4 Removing a Group

4.2.4.4.i Synopsis

amgr rm group -n <group name>

4.2.4.4.ii Description

Removes specified group from Budgets, unless the group has any past or current associated transactions, in which case the group is made inactive.

4.2.4.4.iii Options

-n, --name <group name>

String. Name of the group to remove.

4.2.4.5 Removing a Cluster

4.2.4.5.i Synopsis

amgr rm cluster -n <PBS server>

4.2.4.5.ii Description

Removes the specified cluster from Budgets, unless the cluster has any past or current associated jobs or transactions, in which case the cluster is made inactive.

4.2.4.5.iii Options

-n, --name <PBS server>

String. Name of the cluster to remove.

4.2.4.6 Removing a Period

4.2.4.6.i Synopsis

amgr rm period -n <period name>

4.2.4.6.ii Description

Removes specified period from Budgets, if the period and all parent periods have no associated jobs or transactions. If either the period or a parent has any associated jobs or transactions, the period is made inactive.

See section 1.7.1, "Periods, Allocation Periods, Billing Periods", on page 18.

4.2.4.6.iii Options

-n, --name <period name>

String. Name of the period to remove.

4.2.4.7 Removing a Service Unit

4.2.4.7.i Synopsis

amgr rm serviceunit -n <service unit name>

4.2.4.7.ii Description

Removes specified service unit from Budgets, unless the service unit has any past or current associated transactions, in which case the service unit is made inactive.

4.2.4.7.iii Options

-n, --name <service unit name>

String. Name of service unit to remove.

If this is a standard service unit, the name must match name used in formula file.

Blank spaces are not allowed.

If this is a standard service unit, you must also remove this service unit from all formulas, otherwise jobs will not run.

4.2.4.7.iv Command Examples

Example 4-22: Removing a standard service unit named cpu_hrs:

```
amgr rm serviceunit -n cpu_hrs
```

Example 4-23: Removing a dynamic service unit named luster:

```
amgr rm serviceunit -n luster
```

4.2.5 Getting Reports on Elements

The `amgr report` command allows you to get reports for projects, groups, jobs, transactions, and users.

amgr report {user | project | group | transaction}

Use the `-l` option to the `amgr report` commands for more detailed information.

4.2.5.1 Required Privilege

A *user* can get a report on their own usage, jobs, and transactions, and on any project account with which the user is associated.

A *manager* can get reports on users and projects that are associated with any groups with which the manager is associated.

A member of a project can get a report on that project.

An *admin* or *investor* can get a report on any group and project.

4.2.5.2 Getting User Reports

4.2.5.2.i Synopsis

amgr report user -n <username> [-s <service unit name> | -t <service unit type>] [-h] [-p <period>] [-S <start date>] [-E <end date>] [-l] [-o <output file>] [-r] [-A]

4.2.5.2.ii Description

By default, this prints information for all standard service units for the current period that is lowest in the hierarchy (shortest time division). You can refine your output by specifying service unit name and type.

By default, this prints the report to the screen in human-readable tables. You can print to a file, and you can print the report in raw (CSV) format.

4.2.5.2.iii Options

-n, --name <username>

String. Username on which to get report.

-s, --serviceunit <service unit name>

Prints report for specified service unit.

If you do not specify a service unit, the report includes all service units of the specified type. If you do not specify type, it is *SU_STANDARD*.

-t, --sunit-type <service unit type>

Use this option to see dynamic service units. By default, this command prints only standard service units.

Cannot be used with `-l`, `-g`, or `-h` options.

Type can be one of *SU_STANDARD* or *SU_DYNAMIC*.

Default: *SU_STANDARD*

-g, --global-view

Lists project details and a summary of all transactions with a detailed listing of each transaction in JSON format.

Cannot be used with `-t SU_DYNAMIC`.

-h, --stakeholder-info

Lists groups which have invested in the user and their invested amounts.

Cannot be used with `-t SU_DYNAMIC`.

-p, --period <period name>

Specifies report period.

Cannot be used with `-S` and `-E` options.

Default: current period that is lowest in hierarchy (shortest time division)

-S, --start-date <start date>

Reports activity starting at this date. Report includes created and updated transactions.

Requires `-l` or `-g` option.

Cannot be used with `-p` option.

Format: YYYY-MM-DD HH:MM:SS

-E, --end-date <end date>

Reports activity ending at this date. Report includes created and updated transactions.

Requires `-l` or `-g` option.

Cannot be used with `-p` option.

Format: YYYY-MM-DD HH:MM:SS

-l, --list-info

Lists all transactions that have happened for the specified user.

Use the -l switch to get the report in long format, containing the transaction_id, transaction_date, transaction_time, entity, transaction_type, transaction_user, type, serviceunit, amount, balance, reconciled, period, am_mode, and comment, in columns.

Cannot be used with `-t SU_DYNAMIC`.

-o, --out-file <output filename>

Budgets prints the report in a human-readable form to the specified output file.

Without this option, Budgets prints the report to the screen.

-r, --raw-output

Print report in raw (CSV) form with no padding. This form is easier to parse but harder for a human to read.

-A, --allocated-view

For listing investor information. Lists remaining credit allocated from this investor to each group in which the investor invested.

4.2.5.2.iv Output Format

Output for the report contains the Name, Service Unit, Period, Opening Balance, Total Credits, Total Debits, Total Debits (Reconciled), Total Debits (Authorized), and Net Balance.

Opening Balance

Opening balance of user account on specified start date

Total Credits

Sum of deposits; does not decrease from transfers or withdrawals or usage. Associated with a period.

Total Debits (Reconciled)

Total consumed amount for a period.

Total Debits (Authorized)

Amount held by running jobs plus amount held by unreconciled finished jobs, for a period.

Current balance

Opening Balance + Total Credits - Total Debits - Total Debits (Reconciled) - Total Debits (Authorized). For period.

4.2.5.2.v Command Examples in Postpaid Mode

Example 4-24: User report:

```
amgr report user -n centos
-------------------------------------------------------------------
name     | period   | serviceunit   | total_outstanding   | metadata
-------------------------------------------------------------------
centos   | 2022     | cpu_hrs       | 480.0               | None
```

Example 4-25: User report in long format:

```
amgr report user -n centos -l
```

4.2.5.2.vi Command Examples in Prepaid Mode

Example 4-26: User report in long format:

amgr report user -n <username> -s <service unit> -S <start date> -E <end date> -l

Example 4-27: To report user storage usage:

```
amgr report user -n user1 -t SU_DYNAMIC
-------------------------------------------------------------------------------------------
name  | serviceunit | period  | limit | last_reported_time             | total_consumed
-------------------------------------------------------------------------------------------
user1 | storage     | 2022.feb| 12.0  | 2022-02-11 18:58:09.48498+00:00| 8.0
```

Example 4-28: User report showing dynamic service units:

```
amgr report user -n pbsuser -t SU_DYNAMIC

---------------------------------------
name    | serviceunit | period | limit
---------------------------------------
pbsuser | luster      | 2022   | 600.0
pbsuser | scratch     | 2022   | 800.0

-----------------------------------------------------
| last_reported_time               | total_consumed
-----------------------------------------------------
| 2022-04-07 12:40:22.470078+05:30 | 40
| 2022-04-07 12:40:22.470078+05:30 | 60
```

4.2.5.3 Getting Project Reports

4.2.5.3.i Synopsis

amgr report project -n <project name> [-s <service unit> | -t <service unit type>] [-U] [-h] [-p <period>] [-S <start date>] [-E <end date>] [-l] [-o <output file>] [-r]

4.2.5.3.ii Description

Produces a project report.

By default, this prints information for all standard service units for the current period that is lowest in the hierarchy (shortest time division). You can refine your output by specifying service unit name and type.

By default, this prints the report to the screen in human-readable tables. You can print to a file, and you can print the report in raw (CSV) format.

4.2.5.3.iii Options

-n, --name <project name>

String. Name of project on which to get report.

-s, --serviceunit <service unit name>

Prints report for specified service unit.

If you do not specify a service unit, the report includes all service units of the specified type. If you do not specify type, it is *SU_STANDARD*.

-t, --sunit-type <service unit type>

Use this option to see dynamic service units. By default, this command prints only standard service units.

Cannot be used with `-l`, `-g`, or `-h` options.

Type can be one of *SU_STANDARD* or *SU_DYNAMIC*.

Default: *SU_STANDARD*

-U, --user-wise

Prints consumption, one line per consumer, per service unit. Output includes amount of credit, username, and period.

By default only standard service units are printed; to see dynamic service units, use the -t option.

-g, --global-view

Lists project details and a summary of all transactions with a detailed listing of each transaction in JSON format.

Cannot be used with `-t SU_DYNAMIC`.

-h, --stakeholder-info

Lists groups which have invested in the project and their invested amounts.

Cannot be used with `-t SU_DYNAMIC`.

-p, --period <period name>

Specifies report period.

Cannot be used with `-S` and `-E` options.

Default: current period that is lowest in hierarchy (shortest time division)

-S, --start-date <start date>

Reports activity starting at this date. Report includes created and updated transactions.

Requires `-l` or `-g` option.

Cannot be used with `-p` option.

Format: YYYY-MM-DD HH:MM:SS

-E, --end-date <end date>

Reports activity ending at this date. Report includes created and updated transactions.

Requires `-l` or `-g` option.

Cannot be used with `-p` option.

Format: YYYY-MM-DD HH:MM:SS

-l, --list-info

Lists all transactions that have happened for the specified project.

Use the `-l` option to get the report in long format, containing the transaction_id, transaction_date, transaction_time, entity, transaction_type, transaction_user, type, serviceunit, amount, balance, reconciled, period, am_mode, and comment, in columns.

Cannot be used with `-t SU_DYNAMIC`.

-o, --out-file <output filename>

Budgets prints the report in a human-readable form to the specified output file.

Without this option, Budgets prints the report to the screen.

-r, --raw-output

Print report in raw (CSV) form with no padding. This form is easier to parse but harder for a human to read.

4.2.5.3.iv Output Format

The report is printed as a columns, for name, start_date, end_date, opening_balance, total_credits, total_debits_reconciled, total_debits_authorized, and net_balance.

4.2.5.3.v Command Example for Postpaid Mode

Example 4-29: Project report in postpaid mode:

```
amgr report project -n project1
```

Command output:

```
-------------------------------------------------------------------------
name       | period   | serviceunit   | total_outstanding   | metadata
-------------------------------------------------------------------------
project1   | 2022     | cpu_hrs       | 1440.0              | {}
```

4.2.5.3.vi Command Example for Prepaid Mode

Example 4-30: Report for all standard service units and current lowest period:

```
amgr report project -n p1
```

Command output:

```
-------------------------------------------------------------------------
name | period   | serviceunit | opening_balance | total_credits
-------------------------------------------------------------------------
p1   | DEC-2018 | dollar1     | 0.0             | 3000000.0

-------------------------------------------------------------------------
| total_debits | total_debits_reconciled | total_debits_authorized
-------------------------------------------------------------------------
| 0.0          | 180.0                   | 0.0

--------------------------
| net_balance | metadata
--------------------------
| 2999820.0   | {}
```

Example 4-31: Report for service unit dollar1 for period 2018:

```
amgr report project -n p1 -s dollar1 -p 2018
```

Command output:

```
------------------------------------------------------------------------
name | period | serviceunit | opening_balance | total_credits
------------------------------------------------------------------------
p1   | 2018   | dollar1     | 0.0             | 5000000.0

------------------------------------------------------------------------
| total_debits | total_debits_reconciled | total_debits_authorized
------------------------------------------------------------------------
| 0.0          | 0.0                     | 0.0

-----------------
| net_balance
-----------------
| 5000000.0
```

To get raw output for the project:

```
amgr report project -n p1 -s dollar1 -p 2018 -r
```

Command output:

```
name,period,serviceunit,opening_balance,total_credits,total_debits,total_debits_reconciled,total
    _debits_authorized,net_balance
    p1,2018,dollar1,0.0,5000000.0,0.0,0.0,0.0,5000000.0
```

Example 4-32: Show individual transactions for the service unit dollar1 for the lowest period:

```
amgr report project -n p1 -s dollar1 -l
```

Note that this prints the report in long format, containing the transaction_id, transaction_date, transaction_time, entity, transaction_type, transaction_user, type, serviceunit, amount, balance, reconciled, period, am_mode, and comment, in columns.

Command output:

```
-------------------------------------------------------------------------
transaction_id    | transaction_date | transaction_time | entity
-------------------------------------------------------------------------
1544096706.291656 | 2018-12-06       | 17:15:06.290064  | manager
2042.cluster1     | 2018-12-06       | 17:15:23.760451  | job
2043.cluster1     | 2018-12-06       | 17:15:24.695462  | job
2044.cluster1     | 2018-12-06       | 17:16:24.058123  | job

-------------------------------------------------------------------------------
| transaction_type | transaction_user | type   | serviceunit | amount
-------------------------------------------------------------------------------
| grant            | Manager1         | credit | dollar1     | 3000000.0
| acquired         | amteller         | debit  | dollar1     | 60.0
| acquired         | amteller         | debit  | dollar1     | 60.0
| acquired         | amteller         | debit  | dollar1     | 60.0

-------------------------------------------------------------
| reconciled | period   | comment
-------------------------------------------------------------
| yes        | DEC-2018 | Deposit dollar1 to DEC period
| yes        | DEC-2018 |
| yes        | DEC-2018 |
| yes        | DEC-2018 |
```

Example 4-33: Print individual transactions for the service unit dollar1 for a date range:

```
amgr report project -n p1 -s dollar1 -l -S '2018-12-06' -E '2018-12-06'
```

Note that this prints the report in long format, containing the transaction_id, transaction_date, transaction_time, entity, transaction_type, transaction_user, type, serviceunit, amount, balance, reconciled, period, am_mode, and comment, in columns.

Command output:

```
------------------------------------------------------------------------
transaction_id    | transaction_date | transaction_time | entity
------------------------------------------------------------------------
1544096706.100772 | 2018-12-06       | 17:15:06.098180  | manager
1544096706.291656 | 2018-12-06       | 17:15:06.290064  | manager
2042.cluster1     | 2018-12-06       | 17:15:23.760451  | job
2043.cluster1     | 2018-12-06       | 17:15:24.695462  | job
2044.cluster1     | 2018-12-06       | 17:16:24.058123  | job

-------------------------------------------------------------------------------
| transaction_type | transaction_user | type   | serviceunit | amount
-------------------------------------------------------------------------------
| grant            | Manager1         | credit | dollar1     | 5000000.0
| grant            | Manager1         | credit | dollar1     | 3000000.0
| acquired         | amteller         | debit  | dollar1     | 60.0
| acquired         | amteller         | debit  | dollar1     | 60.0
| acquired         | amteller         | debit  | dollar1     | 60.0

-------------------------------------------------------------
| reconciled | period   | comment
-------------------------------------------------------------
| yes        | 2018     | Deposit dollar1 to parent period
| yes        | DEC-2018 | Deposit dollar1 to DEC period
| yes        | DEC-2018 |
| yes        | DEC-2018 |
| yes        | DEC-2018 |
```

4.2.5.3.vii Project Reports Showing Dynamic Service Units

Example 4-34: Project report in short format:

```
amgr report project -n p1 -t SU_DYNAMIC
-------------------------------------------------------------------------------------
name | serviceunit | period | limit |last_reported_time               | total_consumed
-------------------------------------------------------------------------------------
p1   | luster      | 2022   | 500.0 |2022-04-07 12:40:22.470078+05:30 | 80
p1   | scratch     | 2022   | 800.0 |2022-04-07 12:40:22.470078+05:30 | 100
```

Example 4-35: Project report in user-wise format:

```
amgr report project -n p1 -t SU_DYNAMIC -U

-------------------------------------------------------------------------------------
name | serviceunit | period | limit |last_reported_time | total_consumed | user_consumed
-------------------------------------------------------------------------------------
p1  | luster    | 2022   | 500.0 | 2022-04-07 12:40  |  80  | {"u1": 20.0, "u2": 10.0}
p1  | scratch   | 2022   | 800.0 | 2022-04-07 12:40  | 100  | {"u1": 40.0}
```

Example 4-36: Report project storage data:

```
amgr report project -n proj1 -t SU_DYNAMIC
```

Command output:

```
-------------------------------------------------------------------------------------
name  | serviceunit | period  | limit | last_reported_time              | total_consumed
-------------------------------------------------------------------------------------
proj1 | storage     | 2022.feb| 25.0  | 2022-02-11 18:58:28.270385+00:00 | 30.0
```

4.2.5.4 Getting Group Reports

4.2.5.4.i Synopsis

amgr report group -n <group name> [-h] [-A] [-S <start-date>] [-E <end-date>] [-l] [-o <output-file>] [-r] [-p <period>]

4.2.5.4.ii Description

Produces group report showing deposits and withdrawals.

By default, this prints information for all standard service units for the current period that is lowest in the hierarchy (shortest time division). You can refine your output by specifying service unit name.

By default, this prints the report to the screen in human-readable tables. You can print to a file, and you can print the file in raw (CSV) format.

4.2.5.4.iii Options

-n, --name <group name>

String. Name of the group on which to get report.

-h, --stakeholder-info

For each investor in the group, lists remaining balance for that investor, of what they invested.

-A, --allocated-view

Lists remaining credit allocated from this group to users and projects.

Shows for each project, how much this project has remaining of what the group invested.

Shows for each user, how much this user has remaining of what the group invested.

Cannot filter by project or user.

-S, --start-date <start date>

Reports activity starting at this date. Report includes created and updated transactions.

Requires `-l` or `-g` option.

Cannot be used with `-p` option.

Format: YYYY-MM-DD HH:MM:SS

-E, --end-date <end date>

Reports activity ending at this date. Report includes created and updated transactions.

Requires `-l` or `-g` option.

Cannot be used with `-p` option.

Format: YYYY-MM-DD HH:MM:SS

-l, --list-info

Lists all transactions that have happened for the specified group.

Use the `-l` option to get the report in long format, containing the transaction_id, transaction_date, transaction_time, entity, transaction_type, transaction_user, type amount and reconciled status in columns.

-o, --out-file <output filename>

Budgets prints the report in a human-readable form to the specified output file.

Without this option, Budgets prints the report to the screen.

-r, --raw-output

Print report in raw (CSV) form with no padding. This form is easier to parse but harder for a human to read.

-p, --period-name <period name>

Specifies report period.

Cannot be used with `-s` and `-E` options.

Default: current period that is lowest in hierarchy (shortest time division)

4.2.5.4.iv Group Report Examples

Example 4-37: Default group report:

```
amgr report group -n h1
```

Command output:

```
-------------------------------------------------------------------
name | serviceunit | opening_balance | total_credits | total_debits
-------------------------------------------------------------------
h1   | cpu_hrs     | 0.0             | 100000.0      | 100.0

-------------------------------------------------------------------
| total_allocated | total_accounts_released | net_balance
-------------------------------------------------------------------
| 600.0           | 70.0                    | 99370.0
```

Example 4-38: Long format group report:

```
amgr report group -n h1 -l
```

Command output:

```
-------------------------------------------------------------------------------------
transaction_id     | transaction_date | transaction_time | entity   | transaction_type
-------------------------------------------------------------------------------------
1570782001.2559264 | 2022-10-11       | 13:50:01.253271  | investor | grant
2470123401.5592132 | 2022-10-11       | 13:50:11.967594  | manager  | grant
6470127408.2212197 | 2022-10-11       | 13:50:31.161543  | manager  | grant

-------------------------------------------------------------------------------
transaction_user | type   | serviceunit | amount   | balance  | period | account
-------------------------------------------------------------------------------
root             | credit | cpu_hrs     | 500000.0 | 500000.0 | -      | group1
mgr1             | credit | cpu_hrs     | 1000.0   | 499996.0 | 2022   | Project1
mgr2             | credit | cpu_hrs     | 4.0      | 499992.0 | 2022   | user1
```

Example 4-39: Report in investor format:

```
amgr report group -n h1 -h
```

Command output:

```
-----------------------------------------------------
investor | serviceunit | balance
-----------------------------------------------------
root     | cpu_hrs     | 50000.0
rsv      | cpu_hrs     | 50000.0
```

Example 4-40: Report for primary group accounts:

```
amgr report user -n h1 -h
```

Command output:

```
-------------------------------------------------------------
group | period | serviceunit | balance
-------------------------------------------------------------
h1    | 2022   | cpu_hrs     | 1500.0
h2    | 2022   | cpu_hrs     | 1500.0
```

Example 4-41: Group report in investor format:

This report shows where managers have deposited the group's service units.

```
amgr report group -n h1 -A
```

Command output:

```
------------------------------------------------------------
account | period | serviceunit | balance
------------------------------------------------------------
root    | 2022   | cpu_hrs     | 498976.0
rsv     | 2022   | cpu_hrs     | 498975.0
```

4.2.5.5 Getting Job and Transaction Reports

4.2.5.5.i Synopsis

amgr report transaction [-i <job ID or transaction ID>] [-l] [-N <count>] [-o <output-file>] [-r]

4.2.5.5.ii Description

Produces a report for a job or transaction.

The default report for a job ID is the net cost for the job.

The default report for a transaction ID is a summary of that transaction.

By default, this prints the report to the screen in human-readable tables. You can print to a file, and you can print the report in raw (CSV) format.

4.2.5.5.iii Options

-i, --transaction-id <transaction ID>

String. ID of Job or transaction on which to get report.

-l, --list-info

Lists all transactions that have happened for the specified job or transaction ID.

Use the `-l` option to get the report in long format, containing the transaction_id, transaction_date, transaction_time, entity, transaction_type, transaction_user, type amount and reconciled status in columns.

-N, --non-reconcile <count>

For use without job or transaction ID. Show all non-reconciled jobs that have had *count* or more attempts to reconcile.

For example, `amgr report transaction -N 2` displays all non-reconciled jobs with count >=2.

Budgets attempts to reconcile a job three times; if this doesn't work, Budgets marks the job as non-reconciled.

-o, --out-file <output filename>

Prints the report in a human-readable form to the specified output file.

Without this option, Budgets prints the report to the screen.

-r, --raw-output

Print report in raw (CSV) form with no padding. This form is easier to parse but harder for a human to read.

4.2.5.5.iv Output Format

Output for the report lists columns for transaction_id, project, user_name, and reconciled_service_units.

If a job is not reconciled, it appears only when you use the `-l` option for a long format report.

Use the `-l` switch to get the report for the job or transaction in long format, which lists transaction_id, transaction_date, transaction_time, project, transaction_type, credit or debit, service units, and amounts.

4.2.5.5.v Examples

Example 4-42: Print job report:

```
amgr report transaction -i 2044.cluster1
```

Command output:

```
-------------------------------------------------------------------------------
transaction    | account | user     | reconciled_dollar1 | reconciled_dollar2
-------------------------------------------------------------------------------
2044.cluster1 | p1       | pbsuser | 60.0               | 21120.0
```

Example 4-43: Print long format report for job, showing individual operations:

```
amgr report transaction -i 2044.cluster1 -l
```

Command output:

```
------------------------------------------------------------------------
transaction_id  | transaction_date | transaction_time | account
------------------------------------------------------------------------
2044.cluster1   | 2018-12-06       | 17:17:46.655998  | p1
2044.cluster1   | 2018-12-06       | 17:16:24.058123  | p1
2044.cluster1   | 2018-12-06       | 17:16:24.058123  | p1

-----------------------------------------------
| transaction_type | type  | service_unit
-----------------------------------------------
| acquired         | debit | dollar2
| acquired         | debit | dollar2
| acquired         | debit | dollar1

-----------------------------------
| amount  | period   | comment
-----------------------------------
| 19920.0 | DEC-2018 | overrun:
| 1200.0  | DEC-2018 |
| 60.0    | DEC-2018 |
```

4.2.6 Applying Limits to Dynamic Service Units

amgr limit {user | project}

Apply limits on dynamic service units for projects or users.

4.2.6.1 Synopsis

amgr limit user -n <username> -p <period name> -s <service unit name> <limit value>

amgr limit project -n <project name> -p <period name> -s <service unit name> <limit value>

4.2.6.2 Description

You establish a quota for an external resource by applying a limit to the dynamic service unit representing that resource. Usage of the external resource is reported by an external application. Jobs that use this resource can start only while the job owner has not reached the quota for this period.

Standard service units don't need a limit.

A limit on a dynamic service unit applies to a particular period and for a particular project or user account.

You can apply limits to any period.

All active dynamic service units must have limits set for the current period for jobs to run.

4.2.6.3 Effect of Limits on the Period Hierarchy

- If a parent period has a limit set for a particular dynamic service unit, its children inherit that limit unless the limit is explicitly set by the group manager.
- If you apply a limit to a period, that value overrides any inherited value.
- The default limit is zero unless the period in question inherits a parent's value.

4.2.6.3.i Rules for LImits on Dynamic Service Units

If a dynamic service unit has no limit set on it, the limit is zero. If there are active dynamic service units, all jobs are checked against those quotas, and a zero quota will stop any job from running. Make sure that you don't unintentionally stop non-target users or projects from running jobs:

- Make sure you set the quota for all users and projects
- When you specify the period, make sure you either:
  - Set the desired quota at the top level of the period hierarchy
  - Set a very high quota at the top level of the period hierarchy, and a more restrictive quota for the period you need to control

4.2.6.4 Required Privilege

You must be a manager associated with the group funding the user or project to apply limits to a dynamic service unit for that user or project.

4.2.6.5 Options

-p, --period <period name>

String. Period to which the limit is to be applied.

-s, --serviceunit <service unit name>

String. Service unit to limit.

<limit value>

Float. Budgets reads this as being in the same units as the dynamic service unit.

Default: If a limit is unset, it is zero.

4.2.6.6 Examples

Example 4-44: Set a limit for the project MyProject, for the period named MyQuarter, on the service unit luster, to be 100:

```
amgr limit project -n MyProject -p MyQuarter -s luster 100
```

Example 4-45: Set a quota on storage of 12.0 for user user1 for the period of 2022:

```
amgr limit user -n user1 -s storage 12.0 -p 2022
```

Example 4-46: Set a quota of 25 for storage for the project project1 for the period of 2022:

```
amgr limit project -n project1 -s storage 25.0 -p 2022
```

4.2.7 Syncing Formula File to PBS Complex

4.2.7.1 Synopsis

amgr sync formula -c <cluster>

4.2.7.2 Description

Pulls formula file from the cluster data structure representing the specified PBS complex, pushes it to the specified complex, and imports it into the am_hook and am_hook_periodic hooks at the specified complex.

4.2.7.3 Required Privilege

You must be *admin* to run this command.

4.2.7.4 Options

-c, --cluster <target PBS complex>

String. Name of PBS complex where formula file is to be updated.

4.3 Transaction and Account Checking Commands

The Budgets service units commands and their respective subcommands are listed here:

Table 4-3: Budgets Service Units Commands

Function	Command	Element Subcommands	Required Privilege	Link
Depositing service units	`amgr deposit`	`user, project, group`	*investor* for deposit to group Group *manager* for deposit to user or project account	Depositing Service Units
Checking balance of service units	`amgr check-balance`	`user, project, group`	*user* can check own balance	Checking Service Unit Balance
Withdrawing service units	`amgr withdraw`	`user, project, group`	*investor* to withdraw from group Group *manager* to withdraw from user or project account	Withdrawing Service Units
Transferring service units	`amgr transfer`	`user, project, group`	*admin*	Transferring Service Units
Prechecking service unit balance	`amgr precheck`	`user, project`	*user* can precheck own balance *admin* or *teller* to check other balances	Prechecking Service Unit Balance
Acquiring service units	`amgr acquire`	`user, project`	*admin* or *teller*	Acquiring Service Units
Reconciling service units	`amgr reconcile`	`user, project`	*admin* or *teller*	Reconciling Service Units
Refunding service units	`amgr refund`	`transaction`	*admin*	Refunding Service Units

4.3.1 Depositing Service Units

amgr deposit {user | project | group}

4.3.1.1 Deposit Service Units to User

4.3.1.1.i Synopsis

amgr deposit user -n <username> -s <service unit name> <service unit amount> -p <period> -h <group> [-C <comment>]

4.3.1.1.ii Description

Deposits service units to a user account.

4.3.1.1.iii Required Privilege

You must be *manager* to run this command.

4.3.1.1.iv Options

-n, --name <username>

String. User account to receive service units.

-s, --serviceunits <service unit name> <service unit amount>

String and float. Specifies the service unit to be deposited and the quantity to deposit.

-p, --period <period>

String. Period during which service units are available.

-h, --group <group name>

String. Name of the group from which service units are to be allocated.

-C, --comment <comment>

String. Comment or reason for the deposit. Optional.

Default: no comment

4.3.1.2 Depositing Service Units to Project

4.3.1.2.i Synopsis

amgr deposit project -n <project name> -s <service unit name> <service unit amount> -p <period> -h <group> [-C <comment>]

4.3.1.2.ii Description

Deposits service units to a project.

4.3.1.2.iii Required Privilege

You must be *manager* to run this command.

4.3.1.2.iv Options

-n, --name <project name>

String. Name of project to receive service units.

-s, --serviceunits <service unit name> <service unit amount>

String and float. Specifies the service unit to be deposited and the quantity to deposit.

-p, --period <period>

String. Period during which service units are available.

-h, --group <group name>

String. Name of the group from which service units are to be allocated.

-C, --comment <comment>

String. Comment or reason for the deposit. Optional.

Default: no comment

4.3.1.3 Depositing Service Units to Group

4.3.1.3.i Synopsis

amgr deposit group -n <group name> -s <service unit name> <service unit amount> [-C <comment>]

4.3.1.3.ii Description

Deposits investor service units to a group. This command is run by the investor; the funds invested come from the investor running the command.

4.3.1.3.iii Required Privilege

This command must be run by an *investor*.

4.3.1.3.iv Options

-n, --name <group name>

String. Name of group to receive service units.

-s, --serviceunits <service unit name> <service unit amount>

String and float. Specifies the service unit to be deposited and the quantity to deposit.

Examples: `-s cpu_hrs 100` or `-s cpu_hrs 100.0`

-C, --comment <comment>

String. Comment or reason for the deposit. Optional.

Default: no comment

4.3.2 Checking Service Unit Balance

amgr checkbalance {user | project | group}

4.3.2.1 Required Privilege

A *user* can check their own service unit balance.

A member of a project can check the service unit balance for that project.

An *admin, manager,* or *investor* can check the service unit balance for all groups and projects.

4.3.2.2 Output Format

- For `amgr checkbalance {user | project}`, output is a list of standard service units in name-value pairs and dynamic service units in name-limit-value triplets, in the order in which the service units were created:

```
{"<standard unit 1>": <amount available>,
 "<standard unit 2>": <amount available>,
 "<dynamic unit 1>": {"used": <amount used>, "limit": <limit value>},
 "<dynamic unit 2>": {"used": <amount used>, "limit": <limit value>} }
```

- For `amgr checkbalance group`, output is a list of standard service units in name-value pairs, in the order in which the service units were created:

```
{"<standard unit 1>": <amount available>,
 "<standard unit 2>": <amount available>,}
```

4.3.2.3 Command Example

Example 4-47: For output from `amgr checkbalance {user | project}`, dynamic service unit luster, and standard service units cpu_hrs and gpu_hrs:

```
{"luster": {"used": 0.0, "limit": 300}, "cpu_hrs":0.0, "gpu_hrs":0.0}
```

Example 4-48: For output from `amgr checkbalance group`, standard service units cpu_hrs and gpu_hrs:

```
{"cpu_hrs":0.0, "gpu_hrs":0.0}
```

4.3.2.4 Checking Service Unit Balance for User

4.3.2.4.i Synopsis

amgr checkbalance user -n <username> [-p <period>]

4.3.2.4.ii Description

Check available service unit balance for a user account.

4.3.2.4.iii Options

-n, --name <username>

String. User account to check for available service units.

-p, --period <period>

String. Period during which service units are required.

Default: period is the current period that is lowest in the hierarchy, meaning shortest time span.

4.3.2.5 Checking Service Unit Balance for Project

4.3.2.5.i Synopsis

amgr checkbalance project -n <project name> -p <period>

4.3.2.5.ii Description

Checks available service unit balance for a project.

4.3.2.5.iii Options

-n, --name <project name>

String. Name of project to check for available service units.

-p, --period <period>

String. Period during which service units are required.

4.3.2.6 Checking Service Unit Balance for Group

4.3.2.6.i Synopsis

amgr checkbalance group -n <group name>

4.3.2.6.ii Description

Checks available service unit balance for a group.

4.3.2.6.iii Options

-n, --name <group name>

String. Name of group to check for available service units.

4.3.3 Withdrawing Service Units

amgr withdraw {user | project | group}

4.3.3.1 Withdrawing Service Units from User

4.3.3.1.i Synopsis

amgr withdraw user -n <username> -s <service unit type> <service unit amount> <-p <period> -h <group> [-C <comment>]

4.3.3.1.ii Description

Withdraw service units from a user account. You can withdraw only up to the amount you have deposited.

4.3.3.1.iii Required Privilege

You must be *manager* to run this command.

4.3.3.1.iv Options

-n, --name <username>

String. User account from which to withdraw service units.

-s, --serviceunits <service unit name> <service unit amount>

String and float. Name of service unit to be withdrawn and the quantity to withdraw.

Examples: `-s cpu_hrs 100` or `-s cpu_hrs 100.0`

-p, --period <period>

String. Period from which to withdraw service units.

-h, --group <group name>

String. Group to receive withdrawn service units.

-C, --comment <comment>

String. Comment or reason for the withdrawal. Optional.

Default: no comment

4.3.3.2 Withdrawing Service Units from Project

4.3.3.2.i Synopsis

amgr withdraw project -n <project name> -s <service unit type> <service unit amount> <-p <period> -h <group> [-C <comment>]

4.3.3.2.ii Description

Withdraws service units from a project.

A manager can withdraw only up to the amount they deposited.

4.3.3.2.iii Required Privilege

You must be *manager* to run this command.

4.3.3.2.iv Options

-n, --name <project name>

String. Name of project from which to withdraw service units.

-s, --serviceunits <service unit name> <service unit amount>

String and float. Name of service unit to be withdrawn and the quantity to withdraw.

Examples: `-s cpu_hrs 100` or `-s cpu_hrs 100.0`

-p, --period <period>

String. Period from which to withdraw service units.

-h, --group <group name>

String. Group to receive withdrawn service units.

-C, --comment <comment>

String. Comment or reason for the withdrawal. Optional.

Default: no comment

4.3.3.3 Withdrawing Service Units from Group

4.3.3.3.i Synopsis

amgr withdraw group -n <group name> -s <service unit type> <service unit amount> [-C <comment>]

4.3.3.3.ii Description

Withdraw service units from a group. The investor can remove only the amount of service units that the investor deposited.

4.3.3.3.iii Required Privilege

You must be *investor* to run this command.

4.3.3.3.iv Options

-n, --name <group name>

String. Group from which to withdraw service units.

-s, --serviceunits <service unit name> <service unit amount>

String and float. Name of service unit to be withdrawn and the quantity to withdraw.

Examples: `-s cpu_hrs 100` or `-s cpu_hrs 100.0`

-C, --comment <comment>

String. Comment or reason for the withdrawal. Optional.

Default: no comment

4.3.4 Prechecking Service Unit Balance

amgr precheck {user | project | jobs}

4.3.4.1 Prechecking a User or Project

4.3.4.1.i Synopsis

amgr precheck user -n <username> -c <cluster> [-D <transaction date>] -d <duration> -s <service unit name> <service unit amount> -u <username> -f <formula file>

amgr precheck project -n <project name> -c <cluster> [-D <transaction date>] -d <duration> -s <service unit name> <service unit amount> -u <username> -f <formula file>

4.3.4.1.ii Description

This command is intended to be used internally for prechecking jobs when they are submitted, and you do not need to run it in the normal course of events. It is used to check whether the resources needed to run a particular job are available. Checks whether the project or user has sufficient funds and the specified complex is available to run a job at a specified date for a specific amount of service units.

If AM_BALANCE_PRECHECK is *True* and the check fails, the job is not queued. If AM_BALANCE_PRECHECK is *False* and the check fails, the job is queued.

4.3.4.1.iii Required Privilege

A *user* can precheck their own account.

You must be *admin* or or *teller* to run this command for any other account.

4.3.4.1.iv Options

-n, --name <project name>

String. Name of the project or user to check for available service units.

-c, --cluster <PBS server>

String. PBS complex to check for availability.

-D, --transaction-date <transaction date>

Date. Transaction date and time.

Format: YYYY-MM-DD HH:MM:SS

-d, --duration <duration>

Integer seconds.

Job duration, in seconds.

-s, --serviceunits <service unit name> <service unit value>

String and float. Name of service unit and required amount.

-u, --user <username>

String. User account for whom to precheck service units.

-f, --formula <formula filename>

String. Formula file for cluster.

4.3.4.1.v Output

If the job owner has sufficient credit to run the specified job, there is no output. If the job owner does not have enough credit to run the job, this command prints a message to the job submitter's screen indicating the credit shortfall.

4.3.4.2 Prechecking Jobs

4.3.4.2.i Synopsis

amgr precheck jobs [-v <job string> | -J <job file>] -f <formula file>

4.3.4.2.ii Description

Allows the job submitter to make sure that their credit is sufficient to run jobs.

To use this command on a job, you need to know how much of each service unit is required for that job, so you may need to first get a quote for the job. For job quotes, see "Getting Job Cost Estimate from Budgets", on page 197 of the PBS Professional User's Guide.

The command prints a JSON string of key-value pairs. Each key is a job ID and the corresponding value is *True* or *False*. *True* indicates that the user has sufficient credit to run that job.

You give the command a list of jobs, and the command considers each job in turn. If a job could run, the credit required for that job is not included in the test for the next job. For example, you have 10 service units and you are testing 4 jobs needing 20, 4, 4, and 4 units respectively. In this case, the first job cannot run, the second job is tested against 10 service units and can run, the third job is tested against 6 service units and can run, and the fourth job is tested against 2 service units and cannot run.

The input job ID does not need to be the identifier of an existing job; it is used only to identify whether that job could run.

4.3.4.2.iii Required Privilege

A *user* can precheck their own jobs.

You must be *admin* or or *teller* to run this command for any other account.

4.3.4.2.iv Options

-v, --value <job string>

String. JSON string listing job(s) to be prechecked.

Format:

```
'{
    "<job ID>":{
        "account":<account name>,
        "cluster":<cluster name>,
        "user":<username>,
        "transaction_date":<date>,
        "duration":<duration>,
        "serviceunits":{
            "<service unit1 name>":"<value>","<service unit2 name>":"<value>",...
        }
    }, ...
}'
```

Where:

<job ID>
String used to identify job. Can be arbitrary or can be existing job.

account
String. Project or user account name.

cluster
String. Cluster name.

user
String. Username of job submitter.

transaction_date
Datetime. Transaction date. Format:

'YYYY-MM-DD HH-MM-SS'

duration
Duration. Time required for job to run.

Format: integer seconds

serviceunits
String. List of key-value pairs. Each key is the name of a service unit, and each value is the amount of that service unit required by the job.

Cannot be used with `-J` option.

-J, --json-file <JSON file>

Path to JSON input file listing job(s) to be prechecked. Path can be absolute or relative to directory where command is run.

Format: same as JSON *job string* argument to `-v` option.

Cannot be used with `-v` option.

-f, --formula <formula filename>

String. Path to formula file for cluster. Required. Path can be absolute or relative to directory where command is run.

4.3.4.2.v Output

The command prints a list of key-value pairs in JSON format. Each key is a job ID, and each value is *True* or *False*, where *True* indicates that the user has sufficient credit to run that job.

4.3.4.2.vi Examples

Example 4-49: Check a job using a JSON input string:

```
amgr precheck jobs -v '{"0.myserver":{"account":"project1","cluster":"myser-
   ver","user":"myuser","transaction_date":"2021-11-10 14:27:30","duration":100,"service-
   units":{"cpu_hrs":200.0,"dollar":5.0}}' -f /opt/am/hooks/pbs/my_formula.json
```

Response:

```
{"o.myserver":True}
```

Example 4-50: Check two jobs using a JSON input file:

```
amgr precheck jobs -J /tmp/precheck_data.json -f /opt/am/hooks/pbs/my_formula.json
```

Response:

```
{"o.myserver":True,"1.myserver":False}
```

Where:

```
cat /tmp/precheck_data.json
{
    "0.myserver":{
        "account":"project1",
        "cluster":"myserver",
        "user":"myuser",
        "transaction_date":"2021-11-10 14:27:30",
        "duration":100,
        "serviceunits":{
            "cpu_hrs":200.0,
            "dollar":5.0
        }
    }
    "1.myserver":{
        "account":"myuser",
        "cluster":"myserver",
        "user":"myuser",
        "transaction_date":"2021-11-10 14:27:40",
        "duration":50,
        "serviceunits":{
            "cpu_hrs":100.0,
            "dollar":2.0
        }
    }
}
```

4.3.5 Acquiring Service Units

amgr acquire {user | project}

4.3.5.1 Description

This command is intended to be used for debugging. You do not need to run it in the normal course of events. The Budgets hook performs this operation for normal job processing.

Fetches the service units that are required to run a job from the user or project.

The teller uses this command to acquire service units for a user by taking them from a project or user account.

Run the checkbalance command before running a job to make sure there are enough service units available.

4.3.5.2 Required Privilege

You must be an *admin* or *teller* to run this command.

4.3.5.3 Acquiring Service Units for User

4.3.5.3.i Synopsis

amgr acquire user -n <username> -c <cluster> -s <service unit name> <service unit amount> [-D <transaction date>] -i <job ID> -d <duration> -u <username> [-C <comment>] -R <run count> -f <formula file>

4.3.5.3.ii Options

-n, --name <username>

String. User account from which to fetch service units.

-c, --cluster <PBS server>

String. Name of cluster.

-s, --serviceunits <service unit name> <service unit amount>

String and float. Name of service unit and the quantity required.

Examples: `-s cpu_hrs 100` or `-s cpu_hrs 100.0`

-D, --transaction-date <date>

Date. Transaction date and time.

Format: YYYY-MM-DD HH:MM:SS

-i, --transaction-id <job ID>

Full PBS job ID.

-d, --duration <duration>

Duration. Job duration, in seconds.

-u, --user <username>

String. User account for whom to acquire service units.

-C, --comment <comment>

String. Comment or reason for the acquisition. Optional.

Default: no comment

-R, --run-count <run count>

Integer. Run count for the job.

-f, --formula <formula filename>

String. Formula file for cluster.

4.3.5.4 Acquiring Service Units for Project

4.3.5.4.i Synopsis

amgr acquire project -n <project name> -c <cluster> -s <service unit name> <service unit amount> -D <transaction date> -i <job ID > -d <duration> -u <username> [-C <comment>] -R <run count> -f <formula file>

4.3.5.4.ii Options

-n, --name <project name>

String. Project from which to fetch service units.

-c, --cluster <PBS server>

String. Name of cluster.

-s, --serviceunits <service unit name> <service unit amount>

String and float. Name of service unit and the quantity required.

Examples: `-s cpu_hrs 100` or `-s cpu_hrs 100.0`

-D, --transaction-date <date>

Date. Transaction date and time.

Format: YYYY-MM-DD HH:MM:SS

-i, --transaction-id <job ID>

Full PBS job ID.

-d, --duration <duration>

Duration. Job duration, in seconds.

-u, --user <username>

String. User account for whom to acquire service units.

-C, --comment <comment>

String. Comment or reason for the acquisition. Optional.

Default: no comment

-R, --run-count <run count>

Integer. Run count for the job.

-f, --formula <formula filename>

String. Formula file for cluster.

4.3.6 Reconciling Service Units

amgr reconcile {user | project}

Reconciles service units charged and consumed for jobs. Removes consumed service units from escrow, and returns unused service units to the account, or if the job consumed more than requested it debits more from the job owner's account.

This command is mostly intended to be used for cleanup and debugging. You do not need to run it in the normal course of events. The Budgets hook performs all reconcile operations during normal job processing.

4.3.6.1 Required Privilege

You must be root and *admin* or *teller* to run this command. You must run this command at the PBS server host.

4.3.6.2 Reconciling Service Units for User

4.3.6.2.i Synopsis

amgr reconcile user -n <username> -c <cluster> -d <duration> -f <formula file> -i <job ID> -s <service unit name> <service unit amount> -u <username> [-D <transaction date>] [-C <comment>]

4.3.6.2.ii Description

Reconciles service units for job charged to a user account.

4.3.6.2.iii Options

-n, --name <username>

String. User for whom to reconcile service units.

-c, --cluster <PBS server>

String. Name of cluster.

-d, --duration <duration>

Integer. Job duration, in seconds.

-f, --formula <formula filename>

String. Formula file for cluster.

-i, --transaction-id <job ID>

Job ID.

-s, --serviceunits <service unit name> <service unit amount>

String and float. Name of service unit and the quantity actually consumed.

Examples: `-s cpu_hrs 100` or `-s cpu_hrs 100.0`

-u, --user <username>

String. Job submitter. User account for which service units are to be reconciled. Same as argument to `-n` option.

-D, --transaction-date <date>

Date. Transaction date and time.

Format: YYYY-MM-DD HH:MM:SS

-C, --comment <comment>

Comment or reason for the reconciliation. Optional.

Default: no comment

4.3.6.3 Reconciling Service Units for Project

4.3.6.3.i Synopsis

amgr reconcile project -n <project name> -c <cluster> -d <duration> -f <formula file> -i <job ID> -s <service unit name> <service unit amount> -u <username> [-D <transaction date>] [-C <comment>]

4.3.6.3.ii Description

Reconciles service units for job charged to a project account.

4.3.6.3.iii Options

-n, --name <project name>

String. Project for which to reconcile service units.

-c, --cluster <PBS server>

String. Name of cluster.

-d, --duration <duration>

Integer. Job duration, in seconds.

-f, --formula <formula filename>

String. Formula file for cluster.

-i, --transaction-id <job ID>

Job ID.

-s, --serviceunits <service unit name> <service unit amount>

String and float. Name of service unit and the quantity actually consumed.

Examples: `-s cpu_hrs 100` or `-s cpu_hrs 100.0`

-u, --user <username>

String. Job submitter. User account for which service units are to be reconciled.

-D, --transaction-date <date>

Date. Transaction date and time.

Format: YYYY-MM-DD HH:MM:SS

-C, --comment <comment>

Comment or reason for the reconciliation. Optional.

Default: no comment

4.3.7 Refunding Service Units

amgr refund transaction

4.3.7.1 Description

Refunds some or all of the funds charged for a job to the user or project that funded the job.

Budgets knows who paid for the job, so you do not have to specify where the refund goes.

You can choose to provide a refund for situations such as when a job fails or runs multiple times, for reasons which cannot be attributed to the job owner. You can provide refunds to active and inactive projects and users. You can provide multiple refunds for the same job, but the total refund cannot exceed the amount consumed by the job.

The refund amount is calculated by multiplying the net job cost by the specified refund percentage by the total consumed amount. Total consumed amount is the sum of all transaction amounts of all transactions for a job.

Each group is refunded according to the percentage investment by that group. You can override this using the `-h` option.

4.3.7.2 Required Privilege

You must be *admin* to provide a refund.

4.3.7.3 Synopsis

amgr refund transaction -i <job ID> -r <refund percentage> -p <period> [-h <group>] [-C <comment>]

4.3.7.4 Options

-i, --transaction-id <job ID>

Job ID. Job for which to give a refund.

-r, --refund-percentage <refund percentage>

Integer between 1 and 100. Percentage of current net charge to refund.

-p, --period <period>

String. Period to refund.

Default: current period

-h, --group <group name>

String. Name of group which receives the refund. Overrides normal policy of refunding according to the percentage investment by each group. For use when you get an error message saying that Budgets cannot associate the refund to a group.

-C, --comment <comment>

String. Comment or reason for refund. Optional.

Default: no comment

4.3.8 Transferring Service Units

amgr transfer {user | project | group }

4.3.8.1 Description

Transfers service units from specified project, user, or group, to specified project, user, or group. You can transfer from any of these to any of these.

To transfer between investors, use `amgr transfer group`.

When an investor is unlinked from a group or a group is unlinked from a project, some service units may remain unclaimed and become unusable. The administrator can take ownership of these unclaimed amounts and transfer it back into the budget pool to make it usable again.

A transfer has its own transaction ID.

4.3.8.2 Required Privilege

You must be *admin* to run this command.

4.3.8.3 Transferring Service Units for User

4.3.8.3.i Synopsis

amgr transfer user -n <divesting username> -s <service unit name> <service unit amount> -p <period> -F <divesting group> -T <receiving group> [-U <receiving user>] [-C <comment>]

4.3.8.3.ii Description

Transfer service units from one user to another user, within a group or between groups.

4.3.8.3.iii Options

-n, --name <divesting username>

String. User account from which to take service units.

-s, --serviceunits <service unit name> <service unit amount>

String and float. Service unit name and amount to transfer.

Examples: `-s cpu_hrs 100` or `-s cpu_hrs 100.0`

-p, --period <period>

String. Period from which to take service units.

-F, --from-group <divesting group>

String. Group from which to take service units.

-T, --to-group <receiving group>

String. Group to receive service units.

-U, --dest-user <receiving user>

String. User account to receive service units. Do not use when transferring within same user account.

-C, --comment <comment>

String. Comment or reason for the transfer. Optional.

Default: no comment

4.3.8.4 Transferring Service Units for Project

4.3.8.4.i Synopsis

amgr transfer project -n <divesting project> -s <service unit name> <service unit amount> -p <period> -F <divesting group> -T <receiving group> [-P <receiving project>] [-C <comment>]

4.3.8.4.ii Description

Transfers service units from one project to another, within a group or between groups.

4.3.8.4.iii Options

-n, --name <divesting project>

String. Project from which to take service units.

-s, --serviceunits <service unit name> <service unit amount>

String and float. Service unit name and amount to transfer.

Examples: `-s cpu_hrs 100` or `-s cpu_hrs 100.0`

-p, --period <period>

String. Period from which to take service units.

-F, --from-group <divesting group>

String. Group from which to take service units.

-T, --to-group <receiving group>

String. Group to receive service units.

-P, --dest-project <receiving project>

String. Project to receive service units. Do not use when transferring within the same project.

-C, --comment <comment>

String. Comment or reason for the transfer. Optional.

Default: no comment

4.3.8.5 Transferring Service Units for Investors and Group

4.3.8.5.i Synopsis

amgr transfer group -n <divesting group> -s <service unit name> <service unit amount> -F <divesting investor> -T <receiving investor> -G <receiving group> [-C <comment>]

4.3.8.5.ii Description

Transfers service units from one investor to another investor, within a group or between groups.

4.3.8.5.iii Options

-n, --name <divesting group>

String. Group from which to take service units.

-s, --serviceunits <service unit name> <service unit amount>

String and float. Service unit and amount to transfer.

Examples: `-s cpu_hrs 100` or `-s cpu_hrs 100.0`

-F, --from-investor <divesting investor>

String. Investor from which to take service units.

-T, --to-investor <receiving investor>

String. Investor to receive service units.

-G, --dest-group <receiving group>

String. Group to receive service units. Do not use when transferring within group.

-C, --comment <comment>

String. Comment or reason for the transfer. Optional.

Default: no comment

5 Basic Install and Configure

5.1 Basic Install and Configure Instructions

5.1.1 Assumptions

- You install Budgets and AMS on the PBS server host
- You install Budgets in the default locations
- You use the default billing formula file

5.1.2 Installation

1. Log in as root.
2. Install utilities and `docker`:
   - For CentOS or RedHat:

     Log in as root to the service node (the machine where the AMS module is to be installed).

     ```
     yum install -y yum-utils
     yum-config-manager --add-repo https://download.docker.com/linux/centos/docker-ce.repo
     yum install docker-ce docker-ce-cli containerd.io
     systemctl enable docker
     systemctl start docker
     yum install python3 python3-pip
     yum install openssl
     ```
   - For SLES12 or 15:

     Log in to the machine where Budgets is to be installed.

     For SLES 12:

     ```
     sudo SUSEConnect -p sle-module-containers/12/x86_64 -r ''
     ```

     For SLES 15:

     ```
     sudo SUSEConnect -p sle-module-containers/15.1/x86_64 -r ''
     sudo zypper install docker
     sudo systemctl enable docker.service
     sudo systemctl start docker.service
     ```

     Configure the firewall to allow forwarding of Docker traffic to the external network:

     ```
     Set FW_ROUTE="yes" in /etc/sysconfig/SuSEfirewall2
     zypper install python3-pip
     ```
   - For Ubuntu:

     Log in to the machine where Budgets is to be installed.

     ```
     sudo apt-get update
     sudo apt-get install apt-transport-https ca-certificates curl gnupg-agent software-proper-
         ties-common
     curl -fsSL https://download.docker.com/linux/ubuntu/gpg | sudo apt-key add -
     sudo apt-key fingerprint 0EBFCD88
     ```

     The key should match the second line in the output; validate the last 8 characters. Example of second line:

     9DC8 5822 9FC7 DD38 854A E2D8 8D81 803C 0EBF CD88

     ```
     sudo add-apt-repository "deb [arch=amd64] https://download.docker.com/linux/ubuntu
         $(lsb_release -cs) stable"
     sudo apt-get update
     sudo apt-get install docker-ce docker-ce-cli containerd.io
     sudo apt-get install python3-pip
     ```

     This can install a number of required dependencies, and may take a few minutes.

     ```
     sudo apt-get install openssl
     sudo systemctl enable docker.service
     sudo systemctl start docker.service
     ```

3. On the Budgets server host, download the file containing both the Budgets server and the AMS module. The file-name has the following format:
   PBSPro-budget-server_<release number>-<OS>_x86_64.tar.gz
   For example:
   PBSPro-budget-server_2022.1.0-CentOS7_x86_64.tar.g
4. Untar the file:

tar xvfz PBSPro-budget-server_<release number>-<OS>_x86_64.tar.gz

For example:

```
tar xvfz PBSPro-budget-server_2022.1.0-CentOS7_x86_64.tar.gz
```

This creates the zip files for the Budgets server and the AMS module:

```
budget-manager-server-<OS>-<version>.tar.gz
ams-installer.zip
```

5. Copy `ams_installer.zip` over to the service node
6. On the service node, install AMS:

```
unzip ams-installer.zip
cd ams-installation
python3 -m pip install --upgrade --ignore-installed pbsworks-packager/
/usr/local/bin/pkgr
```
(Please stay in the AMS installer directory for this step)

7. Answer the questions in the dialogue:
   - Choose option: 0
   - Hit Enter until license agreement complete and then answer Yes to accept.
   - Select Enter to continue
   - Choose Option 1 (Provide server hostname/IP address)
     <hostname>
     <IP address>
   - Choose Option: 0 (Skips providing any more machine details)
   - Install Location: <hostname>
   - Authentication Server: <hostname>
   - Authentication Port: Accept Default (If alternative to default 22 for sshd is used then provide alternative port ID)
   - Provide *admin* username: pbsadmin
   - Install Path: Accept default
8. On the service node, edit `/etc/ssh/sshd_config` and add the following lines:

```
Match Address 10.5.0.0/24
PasswordAuthentication yes
```

9. On the service node, make `sshd` reread its configuration file, and restart it:

```
systemctl daemon-reload
systemctl restart sshd
```

10. On the Budgets server host, create certificates:

```
cd /home/pbsadmin/
mkdir budget_certificates
export AM_DBUSER=pbsdata
openssl req -new -x509 -days 3650 -nodes -out budget_certificates/ca.crt -keyout
    budget_certificates/ca.key -subj "/CN=root-ca"
openssl req -new -nodes -out server.csr -keyout budget_certificates/server.key -subj "/CN=local-
    host"
openssl x509 -req -in server.csr -days 3650 -CA budget_certificates/ca.crt -CAkey
    budget_certificates/ca.key -CAcreateserial -out budget_certificates/server.crt
```

```
openssl req -new -nodes -out client.csr -keyout budget_certificates/client.key -subj
    "/CN=${AM_DBUSER}"
openssl x509 -req -in client.csr -days 3650 -CA budget_certificates/ca.crt -CAkey
    budget_certificates/ca.key -CAcreateserial -out budget_certificates/client.crt
rm -f server.csr client.csr
chmod og-rwx budget_certificates/*
```

11. Change to new directory called "am" created by untarring package earlier:

```
cd am/
```

12. Run the Budgets installer, and choose the username you want for the Budgets administrator. In our example we use *pbsadmin* for the administrator username:

```
./install -t server -u pbsadmin -c /home/pbsadmin/budget_certificates
```

5.1.3 Configuration

1. On the Budgets server host and any client hosts, edit /etc/am.conf, and set the parameters appropriately. See section 2.6.7.1, "Budgets Configuration Parameters", on page 44
2. Set PATH for all users:

   ```
   export PATH=/opt/am/python/bin:$PATH
   ```

3. On the Budgets/PBS server host, edit /etc/sudoers, and make it look like this:

   ```
   Cmnd_Alias AM_SERVER_CMD = $AM _EXEC/python/bin/python3 $AM_EXEC/hooks/pbs/pbs_set_formula.py*
   Defaults!AM_SERVER_CMD !requiretty
   Cmnd_Alias AM_CLIENT_CMD = $AM_EXEC/python/bin/amgr sshlogin
   Cmnd_Alias BUDGETS_IMPORTS = $PBS_EXEC/bin/qmgr -c i h am_hook application/x-config default
       .am/tmp*, $PBS_EXEC/bin/qmgr -c i h am_hook_periodic application/x-config default .am/tmp*,
       $PBS_EXEC/bin/qmgr -c export hook am_hook application/x-config default
   pbsadmin ALL=(root) NOPASSWD: BUDGETS_IMPORTS
   Defaults!AM_CLIENT_CMD !requiretty
   Defaults!BUDGETS_IMPORTS !requiretty
   ```

4. Create resources:

   ```
   qmgr -c "c r am_cloud_enabled type=boolean"
   qmgr -c "c r am_job_amount type=string"
   qmgr -c "c r am_job_cache type=string,flag=m"
   qmgr -c "c r am_job_quote type=boolean"
   qmgr -c "c r am_finished_job type=string"
   qmgr -c "c r am_node_cache type=string"
   qmgr -c "set server resources_available.am_finished_job=NA"
   ```

5. Define your billing periods.
6. Set up passwordless ssh for both pbsadmin and amteller. Do these steps once for each one:
   a. Log in to the PBS server as the username who needs passwordless ssh
   b. Check for an existing SSH key pair:

      ```
      ls -al ~/.ssh/id_*.pub
      ```

      If you find existing keys, you can use those or back up the old keys and generate a new one.

      To generate a new SSH key pair:

      ```
      ssh-keygen
      ```

   c. Copy the contents of id_rsa.pub
   d. Log in to the Budgets server as the username who needs passwordless ssh
   e. Check for the .ssh directory. If it does not exist, create it:

      ```
      mkdir -p .ssh
      cd .ssh/
      ```

   f. Create the authorized_keys file in the .ssh directory:

      ```
      vi authorized_keys
      ```

   g. Paste the contents of id_rsa.pub that you copied from the PBS server and save the file.
   h. Change the permission of authorized_keys to *600*:

```
chmod 600 authorized_keys
```

7. Log into the PBS server host
8. Create and configure the am_hook and am_hook_periodic hooks:
   - For prepaid mode:

```
qmgr -c "c h am_hook"
qmgr -c "s h am_hook event='queuejob,runjob,modifyjob,movejob'"
qmgr -c "s h am_hook order=1000"
qmgr -c "c h am_hook_periodic"
qmgr -c "s h am_hook_periodic event=periodic"
qmgr -c "s h am_hook_periodic freq=120"
qmgr -c "i h am_hook application/x-python default  /opt/am/hooks/pbs/am_hook.py"
qmgr -c "i h am_hook_periodic application/x-python default  /opt/am/hooks/pbs/am_hook.py"
qmgr -c "i h am_hook application/x-config default /opt/am/hooks/pbs/<formula file>.json"
qmgr -c "i h am_hook_periodic application/x-config default /opt/am/hooks/pbs/<formula
    file>.json"
qmgr -c "s h am_hook enabled=true"
qmgr -c "s h am_hook_periodic enabled=true"
qmgr -c "s h am_hook alarm=90"
```

   - For postpaid mode:

```
qmgr -c "c h am_hook"
qmgr -c "s h am_hook event='queuejob,modifyjob,movejob'"
qmgr -c "s h am_hook order=1000"
qmgr -c "c h am_hook_periodic"
qmgr -c "s h am_hook_periodic event=periodic"
qmgr -c "s h am_hook_periodic freq=120"
qmgr -c "i h am_hook application/x-python default  /opt/am/hooks/pbs/am_hook.py"
qmgr -c "i h am_hook_periodic application/x-python default  /opt/am/hooks/pbs/am_hook.py"
qmgr -c "i h am_hook application/x-config default /opt/am/hooks/pbs/<formula file>.json"
qmgr -c "i h am_hook_periodic application/x-config default /opt/am/hooks/pbs/<formula
    file>.json"
qmgr -c "s h am_hook enabled=true"
qmgr -c "s h am_hook_periodic enabled=true"
qmgr -c "s h am_hook alarm=90"
```

9. Set configuration parameters:

On the Budgets server host, make sure all of the configuration parameters in section 2.6.7.1, "Budgets Configuration Parameters", on page 44 are set correctly. Especially make sure that AM_MODE is set to the mode you want, because to change modes you need to restart Budgets. In addition, make sure that AM_AUTH_ENDPOINT and AM_LICENSE_ENDPOINT are set correctly.

10. Enable and start Budgets:
    - Enable and start Budgets:
      ```
      systemctl enable pbs_budget
      systemctl start pbs_budget
      ```
    - Check the status of Budgets:
      ```
      systemctl status pbs_budget
      ```
11. Validate Budgets:
    a. Log in as pbsadmin
    b. Test authentication:
       ```
       amgr login
       ```
    c. List users (pbsadmin and amteller):
       ```
       amgr ls user -l
       ```
12. At the Budgets server host, add a cluster to represent the PBS complex with its billing model:
    ```
    amgr add cluster <PBS server> -f am_hook.json
    ```

6 Using Budgets

6.1 Managing Credit with Budgets

Administrators must log into Budgets to perform any administrative tasks, or to manage credit as an investor or a manager, or to reconcile transactions as the teller.

To log in to Budgets:

```
amgr login
<local host password>
```

To log out of Budgets:

```
amgr logout
```

6.2 Tutorials

6.2.1 Tutorial on Configuring and Using Budgets in Prepaid Mode

6.2.1.1 Prerequisites

- A working installation of PBS Professional, with at least two accounts that can submit and run jobs at the complex. In our example, the cluster is named Cluster1, and the users are User1 and User2. Substitute in your own names for the cluster and the users when going through the tutorial.
- Install Budgets: follow the instructions in section 2.4, “Prerequisites”, on page 31, choose a configuration from section 2.2, “Recommended Configurations”, on page 29, and install Budgets according to section 2.6, “Installation Steps for Default Location”, on page 37.
- Create test accounts: In addition to an administrator account, you will need investor, manager, and job submitter accounts. Log in as root:

```
adduser Investor1
passwd Investor1 <password>
adduser Manager1
passwd Manager1 <password>
adduser User1
passwd User1 <password>
adduser User2
passwd User2 <password>
```

6.2.1.2 Tutorial Steps to Configure Budgets

6.2.1.2.i Create Periods

1. Log in as, or switch user to pbsadmin:

   ```
   su pbsadmin
   ```

2. Log into amgr:

   ```
   amgr login
   ```

3. Create a parent period named "2022" representing the year 2022. See section 1.7.1, “Periods, Allocation Periods, Billing Periods”, on page 18.

   ```
   amgr add period -n 2022 -S 2022-01-01 -E 2022-12-31
   ```

4. Create a child period named "2022.Q2" that represents the second quarter of the year 2022, and add it to the parent period:

   ```
   amgr add period -n 2022.Q2 -S 2022-10-01 -E 2022-12-31 -p 2022
   ```

   For the purposes of this tutorial, we are somewhere in the second quarter of 2022, so that this is the default period.

6.2.1.2.ii Add PBS Complex to Budgets

5. Add a cluster named Cluster1 to represent your PBS complex:

   ```
   amgr add cluster -n Cluster1
   ```

6. Deactivate Cluster1:

   ```
   amgr update cluster -n Cluster1 -a False
   ```

7. List Cluster1:

   ```
   amgr ls cluster -a False
   ```

8. Activate Cluster1:

   ```
   amgr update cluster -n Cluster1 -a True
   ```

9. List Cluster1 again:

   ```
   amgr ls cluster
   ```

6.2.1.2.iii Create Standard Service Unit

10. Create a standard service unit named "cpu_hrs" to represent CPU hours. See section 1.7.2, “Service Units”, on page 18. The service unit name must be identical to the one that is configured in the formulas section of the am_hook.json configuration file:

    ```
    amgr add serviceunit -n cpu_hrs -d "CPU Hours"
    ```

6.2.1.2.iv Add Users to Budgets

11. Add a user who will be a group manager, a user who will be an investor, and users User1 and User2 who will submit jobs. When you add a user, you must assign a role, an accounting policy, and at least one cluster:

    ```
    amgr add user -n Manager1 -r manager -A begin_period -c Cluster1
    amgr add user -n Investor1 -r investor -A begin_period -c Cluster1
    amgr add user -n User1 -r user -A begin_period -c Cluster1
    amgr add user -n User2 -r user -A begin_period -c Cluster1
    ```

6.2.1.2.v Create Group

12. Create a group named "test_group" with *manager* Manager1 and *investor* Investor1:

```
amgr add group -n test_group -M Manager1 -I Investor1
```

6.2.1.2.vi Associate Job Submitters with Group

13. Associate User1 and User2 with the group test_group:

```
amgr update user -n User1 -h + test_group
amgr update user -n User2 -h + test_group
```

6.2.1.2.vii Create Project and Give It Cluster and User

14. Create a project named "P1" with accounting policy *begin_period*, cluster Cluster1, user User1 and group test_group:

```
amgr add project -n P1 -A begin_period -c Cluster1 -u User1 -h test_group
```

6.2.1.2.viii Invest in Group

15. Log in as Investor1:

```
amgr login
```

16. Invest 10000 CPU hours in test_group:

```
amgr deposit group -n test_group -s cpu_hrs 10000
```

6.2.1.2.ix Deposit Service Units to Project

17. Log in as Manager1:

```
amgr login
```

18. Allocate 1200 CPU hours from test_group to project P1 for the period 2022.Q2:

```
amgr deposit project -n P1 -s cpu_hrs 1200.00 -p 2022.Q2 -h test_group
```

19. Check the balance of project P1 for the 2022.Q2 period:

```
amgr checkbalance project -n P1 -p 2022.Q2
```

20. Withdraw 200 CPU hours from project P1 for the period 2022.Q2:

```
amgr withdraw project -n P1 -s cpu_hrs 200.00 -p 2022.Q2 -h test_group
```

6.2.1.2.x Deposit Service Units to Users

21. Allocate 1300 CPU hours from test_group to user User1 for the period 2022.Q2:

```
amgr deposit user -n User1 -s cpu_hrs 1300.00 -p 2022.Q2 -h test_group
```

22. Allocate 1400 CPU hours from test_group to user User2 for the period 2022.Q2:

```
amgr deposit user -n User2 -s cpu_hrs 1400.00 -p 2022.Q2 -h test_group
```

6.2.1.3 Tutorial Steps to Use Budgets

6.2.1.3.i Run User Job

23. Log in as User1.
24. Run a sleep job for 10 seconds with a walltime of 2 minutes, and charge it to user User1:

```
qsub -lwalltime=00:02:00 -- /bin/sleep 10
```

25. Check the credit balance for user User1. It will have decreased:

```
amgr checkbalance user -n User1 -p 2022.Q2
```

26. After the job is finished, check the balance again. You should see that the unused amount has been returned:

```
amgr checkbalance user -n User1 -p 2022.Q2
```

6.2.1.3.ii Run Project Job

27. Run a sleep job for 36 seconds with a walltime of 1 hour, and charge it to project P1:

```
qsub -P P1 -lwalltime=01:00:00 -- /bin/sleep 36
```

28. To see the job running:

```
qstat -sw
```

29. Log in as Manager1.
30. Check the credit balance for project P1. It will have decreased:

```
amgr checkbalance project -n P1 -p 2022.Q2
```

31. After the job is finished, check the balance again. You should see that the unused amount has been returned:

```
amgr checkbalance project -n P1 -p 2022.Q2
```

6.2.1.3.iii Non-project User Tries to Run Project Job

32. Log in as User2.
33. Run a sleep job for 10 seconds with a walltime of 2 minutes, and charge it to user User2:

```
qsub -lwalltime=00:02:00 --/bin/sleep 10
```

34. Check the credit balance for user User2. It will have decreased:

```
amgr checkbalance user -n User2 -p 2022.Q2
```

35. After the job is finished, check the balance again. You should see that the unused amount has been returned:

```
amgr checkbalance user -n User2 -p 2022.Q2
```

36. Run a sleep job for 10 seconds with a walltime of 2 minutes, and charge it to project P1:

```
qsub -P P1 -lwalltime=00:02:00 -- /bin/sleep 10
```

This job cannot run, because User2 is not part of project P1.

Example 6-1: Report for all standard service units and current lowest period:

```
amgr report project -n p1
```

6.2.1.3.iv Manager Runs Report on Project

37. Log in as Manager1:

```
amgr login
```

38. Get report on project P1:

```
amgr report project -n P1
```

Command output:

```
-------------------------------------------------------------------------
name | period    | serviceunit | opening_balance | total_credits
-------------------------------------------------------------------------
P1   | 2022      | cpu_hrs     | 0.0             | 1000.0

-------------------------------------------------------------------------
| total_debits | total_debits_reconciled | total_debits_authorized
-------------------------------------------------------------------------
| 0.01         | 1.99                    | 0.0

-------------------------
| net_balance | metadata
-------------------------
| 999.99      | {}
```

6.2.2 Tutorial on Configuring Budgets in Postpaid Mode

6.2.2.1 Prerequisites

- A working installation of PBS Professional, with at least two accounts that can submit and run jobs at the complex. In our example, the cluster is named Cluster1, and the users are User1 and User2. Substitute in your own names for the cluster and the users when going through the tutorial.
- Install Budgets: follow the instructions in section 2.4, “Prerequisites”, on page 31, choose a configuration from section 2.2, “Recommended Configurations”, on page 29, and install Budgets according to section 2.6, “Installation Steps for Default Location”, on page 37.
- Create test accounts: In addition to an administrator account, you will need manager and job submitter accounts. Log in as root:

```
adduser Manager1
passwd Manager1 <password>
adduser User1
passwd User1 <password>
adduser User2
passwd User2 <password>
```

6.2.2.2 Tutorial Steps to Configure Budgets

6.2.2.2.i Create Periods

1. Log in as, or switch user to pbsadmin:

   ```
   su pbsadmin
   ```

2. Log into amgr:

   ```
   amgr login
   ```

3. Create a parent period named "2022" representing the year 2022. See section 1.7.1, “Periods, Allocation Periods, Billing Periods”, on page 18.

   ```
   amgr add period -n 2022 -S 2022-01-01 -E 2022-12-31
   ```

   For the purposes of this tutorial, we are somewhere in 2022, so that this is the default period.

6.2.2.2.ii Add PBS Complex to Budgets

4. Add a cluster named Cluster1 to represent your PBS complex:

   ```
   amgr add cluster -n Cluster1
   ```

5. Deactivate Cluster1:

   ```
   amgr update cluster -n Cluster1 -a False
   ```

6. List Cluster1:

   ```
   amgr ls cluster -a False
   ```

7. Activate Cluster1:

   ```
   amgr update cluster -n Cluster1 -a True
   ```

8. List Cluster1 again:

   ```
   amgr ls cluster
   ```

6.2.2.2.iii Create Standard Service Unit

9. Create a standard service unit named "cpu_hrs" to represent CPU hours. See section 1.7.2, “Service Units”, on page 18. The service unit name must be identical to the one that is configured in the formulas section of the am_hook.json configuration file:

   ```
   amgr add serviceunit -n cpu_hrs -d "CPU Hours"
   ```

6.2.2.2.iv Add Users to Budgets

10. Add a user who will be a group manager, and users User1 and User2 who will submit jobs. When you add a user, you must assign a role, an accounting policy, and at least one cluster:

    ```
    amgr add user -n Manager1 -r manager -A begin_period -c Cluster1
    amgr add user -n User1 -r user -A begin_period -c Cluster1
    amgr add user -n User2 -r user -A begin_period -c Cluster1
    ```

6.2.2.2.v Create Group

11. Create a group named "test_group" with *manager* Manager1:

    ```
    amgr add group -n test_group -M Manager1
    ```

6.2.2.2.vi Associate Job Submitters with Group

12. Associate User1 and User2 with the group test_group:

```
amgr update user -n User1 -h + test_group
amgr update user -n User2 -h + test_group
```

6.2.2.2.vii Create Project and Give It Cluster and User

13. Create a project named "P1" with accounting policy *begin_period*, cluster Cluster1, user User1 and group test_group:

```
amgr add project -n P1 -A begin_period -c Cluster1 -u User1 -h test_group
```

6.2.2.3 Tutorial Steps to Use Budgets

6.2.2.3.i Run User Job

14. Log in as User1.
15. Run a sleep job for 10 seconds with a walltime of 2 minutes, and charge it to user User1:

```
qsub -lwalltime=00:02:00 -- /bin/sleep 10
```

16. After the job is finished, check the credit used by user User1. It will have increased:

```
amgr checkbalance user -n User1 -p 2022
```

6.2.2.3.ii Run Project Job

17. Run a sleep job for 36 seconds with a walltime of 1 hour, and charge it to project P1:

```
qsub -P P1 -lwalltime=01:00:00 -- /bin/sleep 36
```

18. To see the job running:

```
qstat -sw
```

19. Log in as Manager1.
20. After the job is finished, check the credit used by project P1. It will have increased:

```
amgr checkbalance project -n P1 -p 2022
```

6.2.2.3.iii Non-project User Tries to Run Project Job

21. Log in as User2.
22. Run a sleep job for 10 seconds with a walltime of 2 minutes, and charge it to user User2:

```
qsub -lwalltime=00:02:00 --/bin/sleep 10
```

23. After the job is finished, check the credit used by user User2. It will have increased:

```
amgr checkbalance user -n User2 -p 2022
```

24. Run a sleep job for 10 seconds with a walltime of 2 minutes, and charge it to project P1:

```
qsub -P P1 -lwalltime=00:02:00 -- /bin/sleep 10
```

This job cannot run, because User2 is not part of project P1.

6.2.2.3.iv Manager Runs Report on Project

25. Log in as Manager1:

```
amgr login
```

26. Get report on project P1:

```
amgr report project -n P1
```

Command output:

```
---------------------------------------------------------------------
name    | period   | serviceunit   | total_outstanding   | metadata
---------------------------------------------------------------------
P1      | 2022     | cpu_hrs       | 000.01              | {}
```

1 Introduction to Simulate

1.1 What is Simulate?

Simulate allows you to safely replicate and test your site and workload, inside a sandbox. You capture a snapshot of your actual site and workload, then examine and tune the snapshot, without disturbing your production system. You simulate how the workload would run under different conditions. Simulate uses the PBS scheduler to run the simulated workload. You can use Simulate to check whether your configuration meets your business needs, and figure out how to meet your SLAs, perhaps by adding on-premise or cloud compute resources, by adjusting your scheduling parameters, or by changing other configuration parameters. You can also test how your site would perform with changes and increases in your workload, and how you might meet those different needs.

1.1.1 Getting Insight into Workload

You can get insight into your workload, and evaluate whether you are meeting customer requirements and reconciling your organization's needs. You can examine the order in which jobs would run and check whether a job would ever run, and you can check whether a job could be allowed to run if you were to change the system configuration and/or the scheduling policy. You can examine the formula and the contribution from each element in the formula to each job to see how job priority is calculated. You can also see how jobs fall into equivalence classes, which allows you to tune your site configuration appropriately.

Simulate gives you visibility into the interaction of workload and policy in complex environments.

1.1.2 Tuning Your Site Configuration

You can safely experiment with tuning your configuration in order to optimize utilization or throughput, or to better meet your SLAs.

You can take a snapshot of your PBS complex, modify the snapshot to reflect changes you want to test, then simulate running your workload on the modified snapshot. This allows you to test how your site would perform if you made changes to resources such as number of CPUs, amount of memory, number of nodes, etc. For example, you can test whether adding compute hosts would meet your needs, by simulating the addition of on-premise or cloud nodes. You can also discover whether nodes fall into equivalence classes.

1.1.2.1 Tuning Scheduling Parameters

You can experiment with changing the formula and other scheduling parameters to better meet your needs. You can also test how reservations would affect your workload; you can create, status, and run jobs in reservations, all inside a simulation.

Your scheduling policy is the combination that you choose of one or more sub-goals. For example, you might need to meet two particular sub-goals: you might need to prioritize jobs a certain way, and you might need to use resources efficiently. You can choose among various outcomes for each sub-goal. For example, you can choose to prioritize jobs according to size, owner, owner's usage, time of submission, etc.

You can test how changes to site parameters affect how well your site meets each of the following sub-goals:

- Job prioritization and preemption; see "Job Prioritization and Preemption" on page 67 in the PBS Professional Administrator's Guide
- Resource allocation & limits; see "Resource Allocation to Users, Projects & Groups" on page 72 in the PBS Professional Administrator's Guide
- Time slot allocation; see "Time Slot Allocation" on page 74 in the PBS Professional Administrator's Guide
- Job placement optimizations; see "Job Placement Optimization" on page 75 in the PBS Professional Administrator's Guide
- Resource efficiency optimizations; see "Resource Efficiency Optimizations" on page 78 in the PBS Professional Administrator's Guide

Once you have determined the changes you need, you can tune your production system using the fewest, most deliberate alterations necessary. We recommend the following advice on scheduling:

- How to choose a scheduling policy; see "Choosing a Policy" on page 81 in the PBS Professional Administrator's Guide, especially the examples of fitting policy to workload in "Examples of Workload and Policy" on page 90 in the PBS Professional Administrator's Guide

  Note that routing queues do not apply to Simulate, and hooks are not supported in Simulate.
- How to configure a scheduler; see "Configuring a Scheduler" on page 91 in the PBS Professional Administrator's Guide

  Note that dynamic resources are not supported in Simulate.

1.1.3 Examples of Using Simulate

1.1.3.1 Meeting Emergency Needs

You may need to prioritize a specific user's workload to meet an emergency. You can use Simulate to make sure that the site handles the workload correctly, and runs jobs in the desired order so that it meets critical requirements.

1.1.3.2 Handling Special Workloads

For example, you have hosts with GPUs, and you need to make sure that any GPU job that shows up runs right away on the hosts with GPUs, while also continuing to run other jobs on those hosts between GPU jobs.

Simulate lets you maintain utilization levels and maximize your return on investment while handling big shifts in workload and priorities.

1.1.3.3 Handling Weekend Workloads

You may have an unknown number of jobs coming in over the weekend and you want to make sure the weekend jobs run first. For example, a Formula One car on the track has a wing failure, and the design team needs to show that it's not a design failure, but instead something like an impact or a manufacturing error. You know that the design team's workload will need a special policy to expedite their jobs. This lets you ensure that the weekend policy you put in place for the design team performs correctly, before ever touching your production system.

Importantly, you can test whether complex interactions between the special policy and the expected workload would prevent you from meeting your SLAs. You can catch problems before they happen. For example, to give the design team the highest priority, they are given an express queue, but a preexisting server limit of 3 simultaneous jobs remains. Using Simulate, you could quickly see the undesirable behavior and fix the problem. The sandbox environment lets you rapidly test and tune until you are satisfied with the outcome.

1.1.3.4 Planning System Downtime

If you have a large queued workload, and you need to plan for downtime, you can use Simulate to figure out how long it would take to run all queued jobs (drain the queues). This lets you know when maintenance reservations would not disrupt the workload.

1.2 Simulation Terminology

Snapshot

A directory containing subdirectories and files describing a PBS complex and its workload, including queued and running jobs. The snapshot directory includes a copy of `pbs.conf` and the `$PBS_HOME/server_priv` and `$PBS_HOME/sched_priv` directories with their contents, as well as other directories

Primary snapshot

The snapshot on which you run simulations. Typically a snapshot taken from a live PBS complex, either as is or modified.

Output snapshot

An output snapshot produced by running a simulation.

Job equivalence class

A group of jobs that have identical submitters, resource requests, and final queue placement

Node equivalence class

A group of hosts with identical available resources

Discovery command

Command used to discover information about a job, workload, configuration, etc.

1.3 Differences between Simulation and Live Complex

- The PBS commands that you use with Simulate have slightly different implementations from, and are installed in a different location from, the standard PBS commands. When you use the `simsh` wrapper script with a command, the wrapper script calls the correct implementation of that command. If you don't use the wrapper script, you are operating on your live PBS complex. The Simulate commands are designed to operate on a snapshot, which is a directory, rather than on a live PBS complex.
- Some command options do not make sense when you are working with a snapshot. When you are working with a snapshot, keep in mind that you are operating on files rather than a live instance of PBS. For example, if you try to use `tracejob -p <path>`, you are trying to run tracejob with a different path to `PBS_HOME`, but the implementation of `tracejob` for Simulate is designed to use the directories in the snapshot.
- You can use only the commands listed in section 3.2, “List of Commands Used with Simulate”, on page 22 with simulations; other PBS commands are not supported.
- Hooks do not run in simulations. For example, queuejob hooks do not run, so jobs that were queued before you take a snapshot have already been modified by any queuejob hooks, but if you submit new jobs in the simulation, those modifications will not happen. To emulate the behavior of hooks inside the sandbox, you can submit jobs as they would be after hooks have modified them.
- The Budgets tool does not run in simulations, and you cannot take a snapshot of the Budgets tool.
- The Cloud feature does not run in simulations. You cannot directly simulate cloud bursting, but you can indirectly simulate cloud bursting by adding simulated on-premise nodes and associating them with their own queue. See section 2.5.1, “Simulating Cloud Bursting”, on page 17.
- You can capture snapshots only for Linux systems.
- Simulate ignores job environment variables: it does not use the value of the job's Variable_List attribute.
- You cannot create job-specific ASAP reservations or job-specific now reservations.
- Simulate uses only the default scheduler.
- You cannot include history jobs in simulations. (This feature is available in the Simulate tool that is part of Altair Control.)
- The method for adding execution hosts in a simulation is different from that for a live complex; see "Creating Simulated Execution Hosts” on page 12.
- Interactive mode (`qmgr <return>`) is not available for the `qmgr` command. Use `simsh <path to snapshot> qmgr -c "..."` instead.
- Simulate does not run job executables.
- In a simulation, jobs use the requested walltime, not the actual (simulated) time the job would have taken.
- Routing queues are not used by Simulate. If you capture a snapshot of a live system with jobs in a routing queue, or submit jobs to a routing queue in a snapshot, those jobs do not run in the simulation.
- Dynamic resources are not available in Simulate.
- Peer scheduling is not supported in Simulate.

1 Installing and Configuring Simulate

1.1 Supported Platforms

1.1.1 OpenSSL Requirement

PBS requires OpenSSL 1.1.1. If this is not already present on your platform, you must install it.

1.1.2 PBS Components

PBS Professional is made up of the following components:

- PBS Professional server/scheduler daemon on PBS Professional server/scheduler host/head node
- PBS Professional MoM daemon on execution host/compute node, with the following options:
  - On premise
  - Burst in cloud via PBS Cloud (optional)
- PBS Professional client commands on PBS submission host/client host
- PBS Professional communication daemon on communication host
- PBS Cloud module on service node (where AMS module runs) (optional)
- Budgets server on Budgets head node (optional)
- Budgets AMS module on service node (where PBS Cloud module runs) (optional)
- Budgets client commands on Budgets client host (optional)
- Simulate module:
  - When using PBS Cloud, Simulate must be installed on PBS Professional server/scheduler host
  - When not using PBS Cloud, Simulate can be installed on any supported host

1.1.3 Supported Platforms for PBS Components

PBS components are supported on the following platforms. A **(d)** indicates that support is deprecated:

Table 1-1: Supported Platforms

Maker	Version	Chip set	Components							
			PBS Professional				Cloud + AMS		Budgets	Simulate
			Server Sched	MoM on prem	Comm	Client cmds	Cloud module + AMS	MoM burst node	Head node + client cmds	Head node
CentOS	7	x86_64	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No
	7	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	No
Red Hat Enterprise Linux RHEL	7	x86_64	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
	7	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
	7 MLS	x86_64	Yes	Yes	Yes	Yes	No	No	No	No
	8	x86_64	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
	8	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
Rocky Linux	8	x86_64	Yes	Yes	Yes	Yes	No	Yes	No	No
	8	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	No
SUSE SLES	12	x86_64	Yes	Yes	Yes	Yes	Yes *	Yes	Yes	Yes
	12	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	No
	15	x86_64	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes
	15	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
Ubuntu	18.04	x86_64	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes
	18.04	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
	20.04	x86_64	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes
	20.04	ARM64	Yes	Yes	Yes	Yes	No	Yes	No	Yes
HPE Cray Shasta	1.1 SLES 15	x86_64	Yes	Yes	Yes	Yes	Yes *	No	Yes *	Yes
	1.1 RHEL 7	x86_64	Yes	Yes	Yes	Yes	No	No	No	Yes
NEC SX-Aurora TSUBASA			Yes	Yes	Yes	Yes	No	No	No	Yes
Windows	10 Pro	x86_64	No	Yes	No	Yes	No	Yes	No	No

Table 1-1: Supported Platforms

Maker	Version	Chip set	Components							
			PBS Professional				Cloud + AMS		Budgets	Simulate
			Server Sched	MoM on prem	Comm	Client cmds	Cloud module + AMS	MoM burst node	Head node + client cmds	Head node
	11 Pro	x86_64	No	Yes	No	Yes	No	Yes	No	No
	Server 2016	x86_64	No	Yes	No	Yes	No	Yes	No	No
	Server 2019	x86_64	No	Yes	No	Yes	No	Yes	No	No

1.1.3.1 * SLES Restrictions for Cloud and Budgets Nodes

The following restrictions apply when using SLES on service node host for PBS Cloud or head node host for Budgets:

- Each SLES host must be registered with the SUSE Customer Center via SUSEConnect, and have a support contract. This happens automatically for cloud nodes.
- SLES hosts require Docker Enterprise Edition.

1.1.4 Supported Platforms for Nodes Burst in Cloud

- Linux: any Linux platform that supports both PBS MoM and `cloud-init`
- Windows: 10, Server 2012

All versions of `cloud-init` are supported.

1.1.5 Restrictions on Simulate Module Location when Using PBS Cloud

If you will use the PBS Cloud module, you must install Simulate on the PBS Professional server/scheduler host (the PBS Professional head node).

1.2 Prerequisites

- Altair License Manager 14.5+
- PBSProNodes or PBSProSockets 20.0 License Feature

1.2.1 Required Storage and Processors

- Simulate requires a minimum of 300MB of storage, 1 CPU, and 1GB of RAM to run.
- Memory consumption depends on the size of the snapshot being analyzed. At minimum you'll need 500 MB of RAM, but typically less than 2 GB.

1.3 Where to Install Simulate

- If you will use the PBS Cloud module, you must install Simulate on the PBS Professional server/scheduler host (the PBS Professional head node).
- If you will not use the PBS Cloud module, you can install Simulate on any host that can reach the Altair License Manager.

1.4 Installation

1. Untar the Simulate package:

   tar xvfz PBSPro-sim_2022.1.0-<OS><OS version>_x86_64.tar.gz

   For example:

   tar xvfz PBSPro-sim_2022.1.0-SLES15_x86_64.tar.gz

2. Change directory:

   cd PBSPro-sim_2022.1.0

1.5 Configuration

1.5.1 Configure Licensing for Simulate

The Simulate configuration file is named "sim.conf" and is in the installation directory.

In this file, edit the licensing parameter, and set it to *<port>@<license server host>*:

```
SIM_LICENSE_LOCATION=6200@<license server>
```

For example:

```
SIM_LICENSE_LOCATION=6200@mylicensehost
```

1.5.2 Set Path to Snapshot Directory

Optionally, if you want to, you can set the PBS_SNAPSHOT_PATH parameter in `sim.conf` to be the path to the snapshot directory. If you are working repeatedly on the same snapshot, this can make your command execution easier.

1.6 Setting Up User Environment

Set up your environment to point to the `simsh` wrapper command for simulator:

export PATH=/<your install path>/PBSPro-sim_2022.1.0:$PATH

2 Using Simulate

2.1 Basics of Using Simulate

Simulate operates on a snapshot of your site and workload using the same methods as for a live PBS complex. You use the `sim` command to run simulations, and you use PBS commands to modify and examine snapshots. The commands you can use with Simulate are listed in Chapter 3, "Simulate Command Reference", on page 21. To use one of these commands on a snapshot, you must call it using the `simsh` wrapper script.

To inspect or modify a snapshot, you operate on the snapshot the same way you would on a live PBS complex.

By default, when you run a simulation, it runs until all runnable jobs are finished; you can specify the amount of simulated time or number of cycles.

- To capture a snapshot, use the `pbs_snapshot` command on a live PBS complex. This does not require the wrapper script:

  pbs_snapshot [options to pbs_snapshot] -o <output path>

  See section 2.2.1, “Taking a Snapshot of a Live PBS Complex”, on page 6
- To inspect a snapshot, give the `simsh` wrapper script a snapshot and a PBS command:

  simsh <path to snapshot> <PBS command> [<options to PBS command>]

  For example, to get server information about your snapshot:

  ```
  simsh <path to snapshot> qstat -Bf
  ```

  See section 2.2.3, “Inspecting Snapshot Contents”, on page 10
- To modify a snapshot, such as changing a resource or attribute or submitting jobs, give `simsh` a snapshot and the PBS command:

  simsh <path to snapshot> <PBS command> [<options to PBS command>]

  For example, to modify the node named Node1 to have 16 cores:

  ```
  simsh <path to snapshot> qmgr -c "s n Node1 resources_available.ncpus=16"
  ```

  See section 2.2.4, “Modifying Your Snapshot”, on page 11
- To change a configuration file in a snapshot, you edit the appropriate file in the snapshot.

  See section 2.2.4.1, “Editing Files in a Snapshot”, on page 11
- To run a simulation, give the `simsh` wrapper script a snapshot and the `sim` command:

  simsh <path to snapshot> sim [sim options]

  For example, to run a simulation of your workload for 600 seconds:

  ```
  simsh <path to snapshot> sim -t 600
  ```

  See section 2.3.2, “Using the sim Command to Run a Simulation”, on page 14

2.2 Working with Snapshots

Each snapshot is the basis for a simulated universe. A snapshot is a directory containing subdirectories and files describing the PBS complex and its workload, including queued and running jobs. You can use a snapshot of your existing workload, or you can take a snapshot and then modify it in almost any way that you can modify your existing PBS complex. You create snapshots either by taking a snapshot of a live PBS complex, or by running a simulation, which produces an output snapshot.

2.2.1 Taking a Snapshot of a Live PBS Complex

To take a snapshot of a live PBS complex, run the pbs_snapshot command. You must specify an output path:

pbs_snapshot -o <output_path>

The command creates a tar archive at the specified location.

If you want to be able to examine the behavior of a workload, capture a snapshot of a complex where jobs are queued.

If you want to capture only PBS configuration information and queued and running jobs, use the `--basic` option:

pbs_snapshot --basic -o <output_path>

To be able to use the snapshot, first unpack the snapshot:

tar xvfz <snapshot name>.tgz

For example:

```
tar xvfz snapshot_20220708_15_54_57.tgz
```

2.2.2 What Does a Snapshot Contain?

A snapshot produced by the `pbs_snapshot` command arrives as a tarball. A snapshot produced as the output of the `sim` command is not a tarball.

A snapshot is a directory containing subdirectories and files describing the PBS complex and its workload, including queued and running jobs. The snapshot directory includes a copy of `pbs.conf` and the `$PBS_HOME/server_priv` and `$PBS_HOME/sched_priv` directories with their contents, as well as other directories where you might need to examine or modify parameters.

If you run `simsh <path to snapshot> sim -L`, the command writes the scheduler logs in the `sched_logs` directory in the snapshot.

The pbs_snapshot command detects which daemon or daemons are running on the host where it is collecting information, and captures daemon and system data accordingly. The pbs_snapshot command captures data from all multischeds. If no PBS daemons are running, the command collects system information. The output tarball contains information about the host specified via the -H option, or if that is not specified, the local host. If you specify additional hosts, the command creates a tarball for each additional host and includes it as a sub-tarball in the output. You can optionally anonymize the PBS data in a snapshot. The main tarball contains the following directory structure, files, and tarballs, and lists which of those elements appear in a tarball produced by the --basic and --config-only options:

Table 2-1: Contents of Snapshot

Directory or File	Directory Contents	Description	In Basic	In Config Only
server/	qstat_B.out	Output of qstat -B		
	qstat_Bf.out	Output of qstat -Bf	Yes	Yes
	qmgr_ps.out	Output of qmgr print server		
	qstat_Q.out	Output of qstat -Q		
	qstat_Qf.out	Output of qstat -Qf	Yes	Yes
	qmgr_pr.out	Output of qmgr print resource		
server_priv/	Copy of the PBS_HOME/server_priv directory. Core files are captured separately; see core_file_bt/.		resourcedef	resourcedef config
	accounting/	Accounting logs from PBS_HOME/server_priv/accounting/ directory for the number of days specified via --accounting-logs option		
server_logs/	Server logs from the PBS_HOME/server_logs directory for the number of days specified via --daemon-logs option			
job/	qstat.out	Output of qstat		
	qstat_f.out	Output of qstat -f	Yes	
	qstat_f_F_json.out	Output of qstat -f -F json		
	qstat_t.out	Output of qstat -t		
	qstat_tf.out	Output of qstat -tf		
	qstat_x.out	Output of qstat -x		
	qstat_xf.out	Output of qstat -xf		
	qstat_ns.out	Output of qstat -ns		
	qstat_fx_F_dsv.out	Output of qstat -fx -F dsv		
	qstat_f_F_dsv.out	Output of qstat -f -F dsv		

Table 2-1: Contents of Snapshot

Directory or File	Directory Contents	Description	In Basic	In Config Only
node/	pbsnodes_va.out	Output of pbsnodes -va	Yes	
	pbsnodes_a.out	Output of pbsnodes -a		
	pbsnodes_avSj.out	Output of pbsnodes -avSj		
	pbsnodes_aSj.out	Output of pbsnodes -aSj		
	pbsnodes_avS.out	Output of pbsnodes -avS		
	pbsnodes_aS.out	Output of pbsnodes -aS		
	pbsnodes_aFdsv.out	Output of pbsnodes -aF dsv		
	pbsnodes_avFdsv.out	Output of pbsnodes -avF dsv		
	pbsnodes_avFjson.out	Output of pbsnodes -avF json		
	qmgr_pn_default.out	Output of qmgr print node @default		
mom_priv/	Copy of the PBS_HOME/mom_priv directory. Core files are captured separately; see core_file_bt/.			mom_priv/config, only from server host
mom_logs/	MoM logs from the PBS_HOME/mom_logs directory for the number of days specified via --daemon-logs option			
comm_logs/	Comm logs from the PBS_HOME/comm_logs directory for the number of days specified via --daemon-logs option			
sched_priv/	Copy of the PBS_HOME/sched_priv directory, with all files. Core files are not captured; see core_file_bt/.		Yes	
sched_logs/	Scheduler logs from the PBS_HOME/sched_log directory. For a snapshot of a live PBS complex, this is for the number of days specified via pbs_snapshot --daemon-logs. For a simulation output snapshot, this is for the time simulated via simsh <path to snapshot> sim -L.			
sched_priv_<multisched name>/	Copy of the PBS_HOME/sched_priv_<multisched name> directory, with all files. Core files are not captured; see core_file_bt/.		Yes	dedicated_time holidays resource_group sched_config
sched_logs_<multisched name>/	Multisched logs from the PBS_HOME/sched_log_<multisched name> directory for the number of days specified via --daemon-logs option			
reservation/	pbs_rstat_f.out	Output of pbs_rstat -f	Yes	
	pbs_rstat.out	Output of pbs_rstat		
scheduler/	qmgr_lsched.out	Output of qmgr list sched	Yes	Yes

Table 2-1: Contents of Snapshot

Directory or File	Directory Contents	Description	In Basic	In Config Only
hook/	qmgr_ph_default.out	Output of `qmgr -c 'print hook @default'`		Yes
	qmgr_lpbshook.out	Output of `qmgr -c 'list pbshook'`	Yes	Yes
datastore/	pg_log/	Copy of the PBS_HOME/datastore/pg_log directory for the number of days specified via `--daemon-logs` option		
core_file_bt/	Stack backtrace from core files			
	sched_priv/	Files containing the output of `thread apply all backtrace full` on all core files captured from PBS_HOME/sched_priv		
	sched_priv_<multi-sched name>	Files containing the output of `thread apply all backtrace full` on all core files captured from PBS_HOME/sched_priv_<multisched name>		
	server_priv/	Files containing the output of `thread apply all backtrace full` on all core files captured from PBS_HOME/server_priv		
	mom_priv/	Files containing the output of `thread apply all backtrace full` on all core files captured from PBS_HOME/mom_priv		
	misc/	Files containing the output of `thread apply all backtrace full` on any other core files found inside PBS_HOME		

Table 2-1: Contents of Snapshot

Directory or File	Directory Contents	Description	In Basic	In Config Only
system/	pbs_probe_v.out	Output of pbs_probe -v		
	pbs_hostn_v.out	Output of pbs_hostn -v $(hostname)		
	pbs_environment	Copy of PBS_HOME/pbs_environment file		Yes
	os_info	Information about the OS		Yes
	process_info	List of processes running on the system when the snapshot was taken. Output of ps -aux | grep [p]bs on Linux systems, or tasklist /v on Windows systems		
	ps_leaf.out	Output of ps -leaf. Linux only.		
	lsof_pbs.out	Output of lsof | grep [p]bs. Linux only.		
	etc_hosts	Copy of /etc/hosts file. Linux only.		
	etc_nsswitch_conf	Copy of /etc/nsswitch.conf file. Linux only.		
	vmstat.out	Output of the command vmstat. Linux only.		
	df_h.out	Output of the command df -h. Linux only.		
	dmesg.out	Output of the dmesg command. Linux only.		
pbs.conf	Copy of the pbs.conf file on the server host		Yes	Yes
ctime	Contains the time in seconds since epoch when the snapshot was taken		Yes	Yes
pbs_snapshot.log	Log messages written by pbs_snapshot		Yes	Yes
<remote hostname>.tgz	Tarball of output from running the pbs_snapshot command at a remote host			

Snapshot Dates and Times

Bear in mind that jobs and reservations that were created before you took the snapshot keep their dates and times, which may be in the past.

2.2.3 Inspecting Snapshot Contents

You can use any of the discovery commands listed in section 3.2, “List of Commands Used with Simulate”, on page 22 to examine your snapshots. Some examples:

- To use qstat to inspect the contents of a snapshot:

simsh <path to snapshot> qstat [qstat options]

For example, to display queued and running jobs:

```
simsh <path to snapshot> qstat -a
```

Or to get server information:

```
simsh <path to snapshot> qstat -Bf
```

- To use qmgr:

  simsh <path to snapshot> qmgr -c "[qmgr options]"

  For example, to list scheduler attributes:

  ```
  simsh <path to snapshot> qmgr -c "l sched <scheduler name>"
  ```

  Or to list all nodes:

  ```
  simsh <path to snapshot> qmgr -c "list node @default"
  ```

  You may find it helpful to use "@default" if you do not know the name of the server.

- To use pbsnodes:

  simsh <path to snapshot> pbsnodes [pbsnodes options]

  For example, to list all vnodes and their attributes:

  ```
  simsh <path to snapshot> pbsnodes -av
  ```

2.2.4 Modifying Your Snapshot

You modify a snapshot the same way you modify a PBS complex, which means that you edit files to change parameters, but you use qmgr (with simsh) to set resources and change most attributes. You can modify anything in a snapshot that you can modify in a live PBS complex. For example you can edit pbs.conf and sched_config, you can change the resources available on hosts, you can create reservations, you can adjust the job sorting formula, etc. You can also submit more jobs to the snapshot if you need to test a different job mix. While you cannot qalter a job, you can delete it and submit a replacement.

2.2.4.1 Editing Files in a Snapshot

To edit a file in a snapshot, change directory into the snapshot directory, then go to the appropriate subdirectory. For example, to edit the default scheduler configuration file:

1. Change directory to the sched_priv directory inside the snapshot directory:
   ```
   cd <path to snapshot>/sched_priv
   ```
2. Edit the configuration file named sched_config

Or to change pbs.conf:

1. Change directory to the snapshot directory:
   ```
   cd <path to snapshot>
   ```
2. Edit pbs.conf

2.2.4.2 Modifying Available Resources on Hosts

You can change the available resources in your snapshot, such as memory, CPUs, etc. You modify available resources using the exact same tools and methods you use for a live PBS complex, but as arguments to simsh.

For example, to modify a snapshot by giving the host named Test1 32 cores:

```
simsh <path to snapshot> qmgr -c "s n Test1 resources_available.ncpus=32"
```

2.2.4.3 Modifying Attribute Values

You can change the values of any attributes in a snapshot that you could change in a live PBS complex:

simsh <path to snapshot> qmgr -c "set <object> attribute = <value>"

For example, to add a setting to the max_run server attribute:

```
simsh <path to snapshot> qmgr -c "set server max_run += [u:PBS_GENERIC=10]"
```

For a complete list of the attributes in a PBS complex, see “Attributes” on page 277 of the PBS Professional Reference Guide.

2.2.4.4 Adjusting Formula

You can adjust your job sorting formula:

```
simsh <path to snapshot> qmgr -c 'set server job_sort_formula = "<formula>"'
```

See "Using a Formula for Computing Job Execution Priority" on page 150 in the PBS Professional Administrator’s Guide.

2.2.4.5 Creating Simulated Execution Hosts

You can simulate creating new execution hosts in a snapshot by cloning existing nodes inside that snapshot. A typical node entry begins with the name of the node, and looks like this:

```
Node1
    last_used_time = Tue Apr 21 15:13:25 2022
    last_state_change_time = Fri May  1 17:20:17 2022
    license = l
    in_multivnode_host = 1
    sharing = default_shared
    resv_enable = True
    resources_assigned.vmem = 0kb
    resources_assigned.ncpus = 0
    resources_assigned.naccelerators = 0
    resources_assigned.mem = 0kb
    resources_assigned.hbmem = 0kb
    resources_assigned.accelerator_memory = 0kb
    resources_available.vnode = testing
    resources_available.ncpus = 0
    resources_available.mem = 0b
    resources_available.host = testing
    resources_available.arch = linux
    pcpus = 1
    state = free
    ntype = PBS
    pbs_version = 2021.1.1.20210320033812
    Port = 15002
    Mom = Node1
```

To clone a node in a snapshot:

1. Go to the snapshot directory:
   cd <path to snapshot>
2. Go to the subdirectory named "node":
   cd node
3. Edit the file named "pbsnodes_va.out"
4. Copy a node similar to the desired new node
5. Append the copy to the file
6. Make sure that the license attribute is set to "l" (lowercase ell)
7. Modify the copy as needed (you can also modify it later via qmgr)

2.2.4.6 Creating Simulated Reservations

You can create advance, standing, job-specific start, and maintenance reservations in a snapshot. You cannot create job-specific ASAP or now reservations. To create a reservation, use the same method as for a live PBS complex.

- For example, to create an advance reservation for 2 CPUs from 8:00 p.m. to 10:00 p.m.:
  simsh <path to snapshot> pbs_rsub -R 2000.00 -E 2200.00 -l select=1:ncpus=2
- For example, to create a standing reservation that runs every day from 8am to 10am, for a total of 10 occurrences:
  simsh <path to snapshot> pbs_rsub -R 0800 -E 1000 - r"FREQ=DAILY;COUNT=10"
- To create a job-specific start reservation:
  simsh <path to snapshot> qsub -Wcreate_resv_from_job=true
- To create a maintenance reservation:
  simsh <path to snapshot> pbs_rsub --hosts <host list>

For more about creating and using reservations, see "Reserving Resources", on page 137 of the PBS Professional User's Guide and "Reservations" on page 195 in the PBS Professional Administrator's Guide.

2.2.4.7 Adding Jobs to a Snapshot

You can add more queued jobs to your snapshot. Job submission is the same as for non-simulated jobs, except that Simulate does not run job executables:

- If you submit a job using the command line to specify directives, the job script must exist but can be empty
- In the simulated world, each job runs until the end of its requested walltime, instead of the amount of time the job would actually have run. For example, if a job requests one hour of walltime, but the job would finish in 5 minutes in the real world, the simulated job runs for one hour.

If you use a job script, Simulate reads job directives from the script. Otherwise it reads them from the qsub command line or from the here document.

To submit a job:

simsh <path to snapshot> qsub ...

For example:

```
simsh formula_one qsub -N sim_job -l select=1:ncpus=32:mem=16gb -l walltime=0:10:00 -- /bin/sleep
    60
```

For detailed job submission instructions, see section 3.14, "qsub", on page 90.

2.2.4.8 Obfuscating Sensitive Snapshot Information

You can prevent a snapshot from containing certain sensitive information by obfuscating that information. You can obfuscate a snapshot when you create it via `pbs_snapshot --obfuscate`, or you can obfuscate an existing snapshot via `pbs_snapshot --obf-snap <path to snapshot>`. When you obfuscate an existing snapshot you can operate on the .tgz file, or on the directory created by untarring a snapshot. If the snapshot contains other snapshots created via `pbs_snapshot --additional-hosts`, you have to obfuscate each snapshot individually.

2.3 How to Run Simulations

When you run a simulation, you are simulating a PBS complex running a workload. The complex and the workload are captured in a snapshot, which you use in the simulation.

By default, each simulation runs until all runnable jobs have been run. If there are jobs that can never run, they remain queued after a simulation finishes.

2.3.1 Prerequisites

Make sure your snapshot contains a valid scheduler formula and the list of queued jobs:

```
simsh <path to snapshot> qstat -a
```

To capture the minimum usable snapshot:

```
pbs_snapshot --basic -o <output path>
```

2.3.2 Using the sim Command to Run a Simulation

To run a simulation, use the `simsh` wrapper script to call the `sim` command, and specify the snapshot:

simsh <path to snapshot> sim [sim options]

Scheduler logs let you use `tracejob` to find out whether a job ran and why. To capture scheduler logs from the simulation:

simsh <path to snapshot> sim -L

For example, to run a simulation of your workload for 600 seconds and capture scheduler logs:

```
simsh snapshot_20220708_15_54_57 sim -L -t 600
```

2.3.3 Running Multiple Simultaneous Simulations

You can run multiple simultaneous simulations, but not on the same snapshot. To run multiple simultaneous simulations, open a terminal window for each simulation and run a simulation in it:

simsh <path to snapshot> sim [sim options]

2.3.4 Simulation Output

Each simulation creates an output snapshot directory, and writes output statistics to the screen. We describe the output contents in section 2.2.2, “What Does a Snapshot Contain?”, on page 6.

2.3.4.1 Simulation Output Snapshot Name

2.3.4.1.i Initial Output Snapshot Name

By default, the name of the simulation output snapshot is the name of the input snapshot with "_out" appended.

For example, running a simulation on the snapshot named "Snap1" produces the result snapshot named "Snap1_out".

You can specify the name of the output snapshot:

simsh <input snapshot> sim -o <output snapshot name>

For example, if your input snapshot is named "Snap1_new", and you want the output snapshot to be named "Snap1_test1":

```
simsh Snap1_new sim -o Snap1_test1
```

2.3.4.1.ii Naming for Multiple Output Snapshots

Each time you run a simulation without specifying a name for the output snapshot, Simulate names the output snapshot with the input snapshot name and appends "_out". If a snapshot with that name already exists, Simulate renames it by appending "_out". For example, if you run a simulation on a snapshot named "Snap1", you get an output snapshot named "Snap1_out". If you run another simulation on "Snap1", you get a new output snapshot named "Snap1_out", and the old "Snap1_out" is renamed "Snap1_out_out".

Simulate gives you just two default output snapshots. If you run a third simulation on "Snap1" without specifying an output name, you get a new output snapshot named "Snap1_out", and the old "Snap1_out_out" is overwritten when the old "Snap1_out" is renamed to "Snap1_out_out"; the old "Snap1_out_out" is not renamed.

2.3.4.2 Simulation Output Contents

Running the `sim` command with no options creates a snapshot containing accounting log files. If you use the `-L` option, the snapshot also contains scheduler log files.

2.3.4.3 Simulation Output Statistics

When you run a simulation, Simulate prints statistics showing how the workload ran through:

- Number of scheduling cycles run: <integer>
- Number of jobs submitted <integer>
- Number of jobs run: <integer>
- Number of jobs left over: <integer>

  These are the jobs which could not be run because the job requested an unavailable queue or resource, the job exceeded a limit, etc.
- Time taken to simulate: <seconds>

Our example snapshot produces this:

```
### Snapshot: snapshot_20220708_15_54_57 ###

Creating usage database for fairshare.
Number of scheduling cycles run: 32
Number of jobs submitted: 0
Number of jobs run: 22
Number of jobs left over: 0
Time taken to simulate: 0
```

2.3.5 Simulating Scheduler Cycles or Duration

By default, each simulation runs until all runnable jobs have been run. If there are jobs that can never run, they remain queued after a simulation finishes. You can simulate what happens when the scheduler runs a certain number of cycles or for a certain amount of simulated time. When you specify a time to simulate, this is the time in the simulated universe, not the actual time. So if you specify for example 600 seconds of simulation, you may have to wait only a few seconds for the simulation to complete.

To specify number of cycles:

simsh <path to snapshot> sim -n <number of cycles>

To specify amount of simulated time:

simsh <path to snapshot> sim -t <number of seconds>

If you specify both, you get the shorter of the two. So if you specify 5 cycles and 600 seconds, but it only takes 100 simulated seconds to run the 5 cycles, your simulation runs for just the 100 simulated seconds.

2.3.6 Simulation Errors

If you get a licensing error: "Error: No valid licenses found, quitting", make sure the licensing prerequisites are met.

2.4 How to Examine Workloads

2.4.1 Examining Job Priority Order

You can see the order in which jobs would be considered for execution by the scheduler. The scheduler computes the priority for each job using the formula. You can examine the formula and the value of each element in the formula for each job in your simulated universe. You do not need to run a simulation to see job priority order.

Take a snapshot of your workload, and use the `simsh` wrapper script to run the `pbs_stat` command on the snapshot:

```
simsh <path to snapshot> pbs_stat --eval-formula
```

2.4.2 Examining Job Execution Timing

After a simulation, you can see the order in which jobs ran, along with their start and end times:

simsh <path to snapshot> pbs_stat -S

2.4.3 Finding Out Whether a Job Can Ever Run

To find out whether a job can ever run, simulate running your workload. Take a snapshot of your workload, then use `simsh` with the `sim` command to run the simulation; see section 2.3, “How to Run Simulations”, on page 14. To generate scheduler logs for your simulation, use the `-L` option:

simsh <path to snapshot> sim -L [other options to sim]

After you have run the simulation, use `simsh` with `qstat` to see jobs that never ran during the simulation:

```
simsh <path to snapshot> qstat -a
```

2.4.4 Finding Jobs that Did Not Run

You can find jobs that have not yet run in an input snapshot, and jobs that never did run in an output snapshot. If you do not specify scheduler cycles or simulation duration, the simulation runs until all runnable jobs are finished. Any jobs that can never run remain queued. You can list them:

simsh <path to snapshot> qstat -a

2.4.5 Figuring Out Why Job Did Not Run

For a specific job, you can see the output of every scheduler cycle for the duration you specify, by examining scheduler logs in a simulation output snapshot. To create a simulation output snapshot that includes scheduler logs, use the `-L` option to the `sim` command.

To examine the scheduler logs for a specific job:

simsh <snapshot> tracejob -n <days> <job ID>

The `tracejob` command finds the data for the specified job, and presents it in chronological order. It examines all of the days from today back to the limit in number of days back you specify in <days>.

If the snapshot was produced on a previous date, take the difference between that date and today into account when you specify <*days*>. For example, if the snapshot was taken 200 days ago, and you want 5 days of log information, specify 205 days. Usually you want to cover the entire snapshot log, so you can just make this very large, for example 1000.

2.4.6 Examining Job Equivalence Classes

Examining job equivalence classes (groups of jobs that have identical submitter and resource and queue requests) can give you insight into your workload. To find job equivalence classes:

```
simsh <path to snapshot> pbs_stat -j
```

2.4.7 Examining Scheduler Logs

You can examine scheduler logs from a simulation output snapshot. If you use the `-L` option, the command writes the scheduler logs in the `sched_logs` directory in the snapshot:

simsh <path to snapshot> sim -L

To see all scheduler logs, you can display or edit them via `cat`, `vi`, etc. To see scheduler logs for a specific job, use tracejob.

2.5 Using Simulations

2.5.1 Simulating Cloud Bursting

Cloud bursting might be a quick and easy way to add execution hosts to your PBS complex. You can test the impact of cloud bursting on your workload by simulating cloud bursting. For example, you can add resources to your snapshot to see the change that cloud bursting could make in how well your site meets its SLAs, such as the overall delivery time for a body of jobs.

Currently you cannot directly simulate dynamic cloud bursting; however, you can indirectly simulate cloud bursting by adding simulated on-premise hosts. Actual cloud nodes require a cloud queue and the cloud bursting hook, but you can simulate cloud nodes by associating your simulated cloud nodes with a special pseudo-cloud queue.

When you simulate cloud bursting, you use a custom resource to associate simulated cloud nodes with a simulated cloud queue. To simulate multiple bursting scenarios, create one simulated cloud queue and some simulated cloud nodes for each scenario, and for each scenario, set the value of the resource used to associate its vnodes with their queue to a value that reflects the scenario, for example, the name of the scenario.

2.5.1.1 Steps to Simulate Cloud Bursting

We'll create one simulated scenario called "Scenario1", and create and use the custom resource named "cloud_link" to associate the vnodes with the pseudo-cloud queue named "Scenario1_queue". Our example snapshot is named "formula_one".

1. For each bursting scenario, create a pseudo-cloud queue, and set its type to "execution":

   ```
   simsh <path to snapshot> qmgr -c "create queue <queue name> queue_type=execution"
   ```

For example:

```
simsh formula_one qmgr -c "create queue Scenario1_queue queue_type=execution"
```

2. Start and enable the queue:

   ```
   simsh <path to snapshot> qmgr -c "set queue <queue name> started=true"
   simsh <path to snapshot> qmgr -c "set queue <queue name> enabled=true"
   ```

For example:

```
simsh formula_one qmgr -c "set queue Scenario1_queue started=true"
simsh formula_one qmgr -c "set queue Scenario1_queue enabled=true"
```

3. Create new simulated execution hosts; follow the steps in section 2.2.4.5, “Creating Simulated Execution Hosts”, on page 12

   In our example, we use "Node1", "Node2", and "Node3" for the names of the simulated cloud nodes.

4. Associate the new execution hosts with the pseudo-cloud queue:

   a. Define a new host-level resource for associating the queue and the new simulated nodes:

   simsh <path to snapshot> qmgr -c 'create resource <new resource> type=string_array, flag=h'

   For example:

   simsh formula_one qmgr -c 'create resource cloud_link type=string_array, flag=h'

   b. Instruct the scheduler to honor the resource. Inside the snapshot directory, in the sched_priv directory, edit the file named "sched_config". Add the new resource to the resources: line:

   resources: "ncpus, mem, arch, host, vnode, <new resource>"

   For example:

   resources: "ncpus, mem, arch, host, vnode, cloud_link"

   c. Set the pseudo-cloud queue's default_chunk for the new resource to the value you are using to associate it with the pseudo-cloud nodes:

   simsh <path to snapshot> qmgr -c "set queue <queue name> default_chunk.<new resource> = <value>"

   For example:

   simsh formula_one qmgr -c "set queue Scenario1_queue default_chunk.cloud_link = Scenario1"

   d. Set the value for the new resource at each new vnode:

   simsh <path to snapshot> qmgr -c "set node <new node name> resources_available.<new resource> = <associating value>"

   For example

   simsh formula_one qmgr -c "set node Node1 resources_available.cloud_link = Scenario1"
   simsh formula_one qmgr -c "set node Node2 resources_available.cloud_link = Scenario1"
   simsh formula_one qmgr -c "set node Node3 resources_available.cloud_link = Scenario1"

5. Submit pseudo-cloud jobs to the pseudo-cloud queue:

   simsh <path to snapshot> qsub ... -q <pseudo-cloud queue> ... <job script>

   For example:

   simsh formula_one qsub -q Scenario1_queue -l select=ncpus=2:mem=16gb -l walltime=1:00:00 MyEmptyScript.sh

2.5.2 Using Simulations to Plan Downtime

To find out when your existing workload will be finished:

1. Take a snapshot of your site and workload, and specify an output path:
   pbs_snapshot -o <output_path>
2. Unpack the snapshot:

   tar xvfz <snapshot name>.tgz
3. Simulate running your workload until all jobs have finished. Create scheduler logs:

   simsh <path to snapshot> sim -L
4. Look for the end date of the last job to finish:

   simsh <path to snapshot> pbs_stat -S

5. Optionally, you can experiment with tuning your configuration so that all jobs are finished sooner. See section 2.4, “How to Examine Workloads”, on page 16
6. Optionally, you can tune your configuration so that the only jobs left running by a particular date are low enough in priority that they could be requeued

2.6 Using the Simulate-Review-Modify-Simulate Cycle

You will probably find that you need to test more than one change to your complex before you reach a satisfactory configuration. You start with a snapshot of your live complex, simulate how the workload runs on it, modify the simulated complex or the workload or both, try it again, and so on. Here's the general idea:

- Get a primary snapshot from a live PBS Professional complex; see section 2.2.1, “Taking a Snapshot of a Live PBS Complex”, on page 6
- Examine the contents of the primary snapshot; see section 2.2.3, “Inspecting Snapshot Contents”, on page 10
  - Examine the order in which jobs would run; see section 2.4.1, “Examining Job Priority Order”, on page 16
- Run a simulation on the primary snapshot; see section 2.3.2, “Using the sim Command to Run a Simulation”, on page 14
- Review your output snapshot; see section 2.4, “How to Examine Workloads”, on page 16
  - See the order and timing with which jobs ran; see section 2.4.2, “Examining Job Execution Timing”, on page 16
- Modify your primary snapshot; see section 2.2.4, “Modifying Your Snapshot”, on page 11
- Examine the order in which jobs would run; see section 2.4.1, “Examining Job Priority Order”, on page 16
- Run a simulation on your modified primary snapshot; see section 2.3.2, “Using the sim Command to Run a Simulation”, on page 14
- Review your new output snapshot; see section 2.4, “How to Examine Workloads”, on page 16
  - See the order and timing with which jobs ran; see section 2.4.2, “Examining Job Execution Timing”, on page 16

3 Simulate Command Reference

The commands described in this chapter have been implemented specifically for use with simulations; you cannot use these implementations in a live PBS complex. To use a simulation command, call The simsh Wrapper Script with a snapshot and the command:

simsh <path to snapshot> <command> <command arguments>

3.1 Command Notation

Optional Arguments

Optional arguments are enclosed in square brackets. For example, in the `qstat` man page, the `-E` option is shown this way:

qstat [-E]

To use this option, you would type:

```
qstat -E
```

Variable Arguments

Variable arguments (where you fill in the variable with the actual value) such as a job ID or vnode name are enclosed in angle brackets. Here's an example from the `pbsnodes` man page:

pbsnodes -v <vnode>

To use this command on a vnode named "my_vnode", you'd type:

```
pbsnodes -v my_vnode
```

Optional Variables

Optional variables are enclosed in angle brackets inside square brackets. In this example from the `qstat` man page, the job ID is optional:

qstat [<job ID>]

To query the job named "1234@my_server", you would type this:

```
qstat 1234@my_server
```

Literal Terms

Literal terms appear exactly as they should be used. For example, to get the version for a command, you type the command, then "--version". Here's the syntax:

qstat --version

And here's how you would use it:

```
qstat --version
```

Multiple Alternative Choices

When there are multiple options and you should choose one, the options are enclosed in curly braces. For example, if you can use either "-n" or "--name":

```
{-n | --name}
```

3.2 List of Commands Used with Simulate

Table 3-1: List of Commands

Command	Description
pbsfs	Show or manipulate PBS fairshare usage data
pbsnodes	Query PBS host or vnode status, mark hosts free or offline, change the comment for a host, or output vnode information
pbs_rstat	Shows status of PBS reservations
pbs_rsub	Creates a PBS reservation
pbs_snapshot	Linux only. Captures PBS workload and configuration data. Not for use with simsh.
pbs_rstat	Displays information about workload and complex
qdel	Deletes PBS jobs
qmgr	Administrator's command interface for managing PBS
Caveats	Selects specified PBS jobs
qstat	Displays status of PBS jobs, queues, or servers
qsub	Submits a job to PBS
sim	For use with snapshots of all-Linux PBS complexes only. Simulates behavior of workload at a PBS complex
tracejob	Extracts and prints log messages for a PBS job

3.3 The simsh Wrapper Script

3.3.1 Synopsis

simsh <path to snapshot> <PBS command> [<options to PBS command>]

3.3.2 Description

The simsh wrapper script operates on a snapshot using PBS commands. You can modify a snapshot, run a simulation using a snapshot, and analyze your workload.

To operate on a snapshot, give the simsh wrapper script a snapshot and a PBS command:

simsh <path to snapshot> <PBS command> [<options to PBS command>]

For example, to get server information about your snapshot:

```
simsh <path to snapshot> qstat -Bf
```

To run a simulation, use simsh to call the sim command:

simsh <path to snapshot> sim [<sim options>]

Available commands are listed in Table 3-1, “List of Commands,” on page 22. Note that you cannot use `simsh` with `pbs_snapshot`.

3.3.3 Options to simsh

--help

Prints usage and exits. This option can only be used alone.

--version

Prints version information and exits. This option can only be used alone.

3.3.4 Arguments to simsh

<path to snapshot>

Snapshot of workload you want to operate on.

<PBS command>

Operation to perform on workload, for example run a simulation on it via the `sim` command, analyze it via the `qstat` command, or modify it via the `qmgr` command.

[<options to PBS command>]

Options to the wrapped command. For example, if the wrapped command is `qstat`, the *command options* can be any valid options to `qstat`.

3.4 pbsfs

Show or manipulate PBS fairshare usage data

3.4.1 Synopsis

Showing usage data:

pbsfs [-c <entity1> <entity2>] [-g <entity>] [-I <scheduler name>] [-p] [-t]

Manipulating usage data:

pbsfs [-d] [-e] [-I <scheduler name>] [-s <entity> <usage value>]

Printing version:

pbsfs --version

3.4.2 Description

You can use the `pbsfs` command to print or manipulate a PBS scheduler's fairshare usage data. You can print the usage data in various formats, described below.

3.4.2.1 Permissions

You must be root to run the `pbsfs` command; if not, it will print the error message, "`Unable to access fairshare data`".

3.4.3 Options to `pbsfs`

You can safely use the following options while jobs are being scheduled:

(no options)
: Same as `pbsfs -p`.

-c <entity1> <entity2>
: Compares two fairshare entities.

-g <entity>
: Prints a detailed listing for the specified entity, including the path from the root of the tree to the entity.

-I <scheduler name>
: Specifies name of scheduler whose data is to be manipulated or shown. Required for multischeds; optional for default scheduler. Name of default scheduler is "default". If not specified, `pbsfs` operates on default scheduler.

-p
: Prints the fairshare tree as a table, showing for each internal and leaf vertex the group ID of the vertex's parent, group ID of the vertex, vertex shares, vertex usage, and percent of shares allotted to the vertex.

-t
: Prints the fairshare tree in a hierarchical format.

--version
: The `pbsfs` command returns its PBS version information and exits. This option can only be used alone.

It is not recommended to be scheduling jobs when you use the following options:

-d

Decays the fairshare tree by the amount specified in the fairshare_decay_factor scheduler parameter.

-e

Trims fairshare tree to just the entities in the resource_group file. Unknown entities and their usage are deleted; as a result the unknown group has no usage and no children.

-s <entity> <usage value>

Sets *entity*'s usage value to *usage value*. Editing a non-leaf entity is ignored. All non-leaf entity usage values are calculated each time you use the pbsfs command to make changes.

3.4.3.1 Output Formats for pbsfs

The pbsfs command can print output in three different formats:

pbsfs -g <entity>

Prints a detailed listing for the specified entity. Example:

```
pbsfs -g pbsuser3
fairshare entity: pbsuser3
Resgroup: 20
cresgroup: 22
Shares: 40
Percentage: 24.000000%
fairshare_tree_usage: 0.832973
usage: 1000 (cput)
usage/perc: 4167
Path from root:
TREEROOT  :     0       1201 / 1.000 = 1201
group2    :    20       1001 / 0.600 = 1668
pbsuser3  :    22       1000 / 0.240 = 4167
```

pbsfs,

pbsfs -p

Prints the entire tree as a table, with data in columns. Example:

```
pbsfs
Fairshare usage units are in: cput
TREEROOT  : Grp: -1     cgrp: 0    Shares: -1     Usage: 1201   Perc: 100.000%
group2    : Grp: 0      cgrp: 20   Shares: 60     Usage: 1001   Perc: 60.000%
pbsuser3  : Grp: 20     cgrp: 22   Shares: 40     Usage: 1000   Perc: 24.000%
pbsuser2  : Grp: 20     cgrp: 21   Shares: 60     Usage: 1      Perc: 36.000%
group1    : Grp: 0      cgrp: 10   Shares: 40     Usage: 201    Perc: 40.000%
pbsuser1  : Grp: 10     cgrp: 12   Shares: 50     Usage: 100    Perc: 20.000%
pbsuser   : Grp: 10     cgrp: 11   Shares: 50     Usage: 100    Perc: 20.000%
unknown   : Grp: 0      cgrp: 1    Shares: 0      Usage: 1      Perc: 0.000%
```

pbsfs -t

Prints the entire tree as a tree, showing group-child relationships. Example:

```
pbsfs -t
  TREEROOT(0)
      group2(20)
           pbsuser3(22)
           pbsuser2(21)
      group1(10)
           pbsuser1(12)
           pbsuser(11)
      unknown(1)
```

3.4.3.2 Data Output by pbsfs

cresgroup, cgrp
: Group ID of the entity

fairshare entity
: The specified fairshare tree entity

fairshare usage units
: The resource for which a scheduler accumulates usage for fairshare calculations. This defaults to *cput* (CPU seconds) but can be set in a scheduler's configuration file.

fairshare_tree_usage
: The entity's effective usage. See "Computing Effective Usage (fairshare_tree_usage)" on page 144 in the PBS Professional Administrator's Guide.

Path from root
: The path from the root of the tree to the entity. A scheduler follows this path when comparing priority between two entities.

Percentage, perc
: The percentage of the shares in the tree allotted to the entity, computed as fairshare_perc. See "Computing Target Usage for Each Vertex (fairshare_perc)" on page 144 in the PBS Professional Administrator's Guide.

Resgroup, Grp
: Group ID of the entity's parent group

Shares
: The number of shares allotted to the entity

usage
: The amount of usage by the entity

usage/perc
: The value a scheduler uses to the pick which entity has priority over another. The smaller the number the higher the priority.

3.4.4 See Also

"Using Fairshare" on page 138 in the PBS Professional Administrator's Guide.

3.5 pbsnodes

Query PBS host or vnode status, mark hosts free or offline, change the comment for a host, or output vnode information

3.5.1 Synopsis

pbsnodes [-o | -r] [-s <server name>] [-C <comment>] <hostname> [<hostname> ...]

pbsnodes [-l] [-s <server name>]

pbsnodes -v <vnode> [<vnode> ...] [-s <server name>]

pbsnodes -a[v] [-S[j][L]] [-F json|dsv [-D <delimiter>]] [- s <server name>]

pbsnodes [-H] [-S[j][L]] [-F json|dsv [-D <delimiter>]] <hostname> [<hostname> ...]

pbsnodes --version

3.5.2 Description

The pbsnodes command is used to query the status of hosts or vnodes, to mark hosts *FREE* or *OFFLINE*, to edit a host's comment attribute, or to output vnode information.

3.5.2.1 Using pbsnodes

To list all vnodes:

```
pbsnodes -av
```

To print the status of the specified host or hosts, run pbsnodes with no options (except the -s option) and with a list of hosts.

To print the command usage, run pbsnodes with no options and without a list of hosts.

To offline a single vnode in a multi-vnoded system, use:

```
qmgr -c "set node <vnode name> state=offline"
```

3.5.2.2 Output

The order in which hosts or vnodes are listed in the output of the pbsnodes command is undefined. Do not rely on output being ordered.

If you print attributes, pbsnodes prints out only those attributes which are not at default values.

3.5.3 Options to pbsnodes

(no options)

If neither options nor a host list is given, the pbsnodes command prints usage syntax.

-a

Lists all hosts and all their attributes (available and used.)

When used with the -v option, lists all vnodes.

When listing a host with multiple vnodes:

The output for the jobs attribute lists all the jobs on all the vnodes on that host. Jobs that run on more than one vnode will appear once for each vnode they run on.

For consumable resources, the output for each resource is the sum of that resource across all vnodes on that host.

For all other resources, e.g. string and Boolean, if the value of that resource is the same on all vnodes on that host, the value is returned. Otherwise the output is the literal string "<various>".

-C <comment>

Sets the comment attribute for the specified host(s) to the value of *comment*. Comments containing spaces must be quoted. The comment string is limited to 80 characters. Usage:

```
pbsnodes -C <comment> <hostname> [<hostname> ...]
```

To set the comment for a vnode:

```
qmgr -c "s n <vnode name> comment=<comment>"
```

-F dsv [-D <delimiter>]

Prints output in delimiter-separated value format. Optional delimiter specification. Default delimiter is vertical bar ("|").

-F json

Prints output in JSON format.

-H <hostname> [<hostname> ...]

Prints all non-default-valued attributes for specified hosts and all vnodes on specified hosts.

-j

Displays the following job-related headers for specified vnodes:

Table 3-2: Output for -j Option

Header	Width	Description
vnode	15	Vnode name
state	15	Vnode state
njobs	6	Number of jobs on vnode
run	5	Number of running jobs at vnode
susp	6	Number of suspended jobs at vnode
mem f/t	12	Vnode memory free/total
ncpus f/t	7	Number of CPUs at vnode free/total
nmics f/t	7	Number of MICs free/total
ngpus f/t	7	Number of GPUs at vnode free/total
jobs	No restriction	List of job IDs on vnode

Note that nmics is a custom resource that must be created by the administrator if you want it displayed here.

Each subjob is treated as a unique job.

-L

Displays output with no restrictions on column width.

-l

Lists all hosts marked as *DOWN* or *OFFLINE*. Each such host's state and comment attribute (if set) is listed. If a host also has state *STATE-UNKNOWN*, it is listed. For hosts with multiple vnodes, only hosts where all vnodes are marked as *DOWN* or *OFFLINE* are listed.

-o <hostname> [<hostname> ...]

Marks listed hosts as *OFFLINE* even if currently in use. This is different from being marked *DOWN*. A host that is marked *OFFLINE* continues to execute the jobs already on it, but is removed from the scheduling pool (no more jobs are scheduled on it.)

For hosts with multiple vnodes, `pbsnodes` operates on a host and all of its vnodes, where the hostname is resources_available.host, which is the name of the parent vnode.

To offline all vnodes on a multi-vnoded machine:

```
pbsnodes -o <name of parent vnode>
```

To offline a single vnode on a multi-vnoded system, use:

```
Qmgr: qmgr -c "set node <vnode name> state=offline"
```

Requires PBS Manager or Operator privilege.

-r <hostname> [<hostname> ...]

Clears *OFFLINE* from listed hosts.

-S

Displays the following vnode information:

Table 3-3: Output for -S Option

Header	Width	Description
name	15	Vnode name
state	15	Vnode state
OS	8	Value of OS custom resource, if any
hardware	8	Value of hardware custom resource, if any
host	15	Hostname
queue	10	Value of vnode's queue attribute
ncpus	7	Number of CPUs at vnode
nmics	7	Number of MICs at vnode
mem	8	Vnode memory
ngpus	7	Number of GPUs at vnode
comment	No restriction	Vnode comment

Note that nmics and OS are custom resources that must be created by the administrator if you want their values displayed here.

-s <server name>

Specifies the PBS server to which to connect.

-v [<vnode> [<vnode> ...]]

Lists all non-default-valued attributes for each specified vnode.

With no arguments, prints one entry for each vnode in the PBS complex.

With one or more vnodes specified, prints one entry for each specified vnode.

When used with `-a`, lists all vnodes.

--version

The `pbsnodes` command returns its PBS version information and exits. This option can only be used alone.

3.5.4 Operands

<server name>

Specifies the server to which to connect. Default: default server.

<hostname> [<hostname> ...]

Specifies the host(s) to be queried or operated on.

<vnode> [<vnode> ...]

Specifies the vnode(s) to be queried or operated on.

3.5.5 Exit Status

Zero

Success

Greater than zero

- Incorrect operands are given
- `pbsnodes` cannot connect to the server
- There is an error querying the server for the vnodes

3.5.6 See Also

The PBS Professional Administrator's Guide, "qmgr" on page 152

3.6 pbs_rstat

Shows status of PBS reservations

3.6.1 Synopsis

pbs_rstat [-B] [-f\-F] [-S] [<reservation ID>...]

pbs_rstat --version

3.6.2 Description

The `pbs_rstat` command shows the status of all reservations at the PBS server. Denied reservations are not displayed.

3.6.2.1 Required Privilege

This command can be run by a user with any level of PBS privilege. For full output, users without manager or operator privilege cannot print custom resources which were created to be invisible to users.

3.6.3 Output

The `pbs_rstat` command displays output in any of brief, short, or full formats.

See section 6.8, “Reservation Attributes”, on page 303 and section 8.6, “Reservation States”, on page 367.

3.6.4 Options to `pbs_rstat`

-B
: Brief output. Displays each reservation identifier only.

-f, -F
: Full output. Displays all reservation attributes that are not set to the default value. Users without manager or operator privilege cannot print custom resources which were created to be invisible to users.

-S
: Short output. Displays a table showing the name, queue, owner, state, start time, duration, and end time of each reservation.

--version
: The `pbs_rstat` command returns its PBS version information and exits. This option can only be used alone.

(no options)
: Short output. Same behavior as `-S` option.

3.6.5 Operands

The `pbs_rstat` command accepts one or more *reservation ID* operands.

Format for an advance or job-specific reservation:

R<sequence number>[.<server name>][@<remote server>]

Format for a standing reservation:

S<sequence number>[.<server name>][@<remote server>]

Format for a maintenance reservation:

M<sequence number>[.<server name>][@<remote server>]

@<remote server> specifies a reservation at a server other than the default server.

3.6.6 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide, "Reservation Attributes" on page 303

3.7 pbs_rsub

Creates a PBS reservation

3.7.1 Synopsis

For advance and standing reservations:

pbs_rsub [-D <duration>] [-E <end time>] [-g <group list>] [-G <auth group list>] [-H <auth host list>] [-I <block time>] [-l <placement>] [-l <resource request>] [-N <reservation name>] [-q <destination>] [-r <recurrence rule>] [-R <start time>] [-u <user list>] [-U <auth user list>] [-W <attribute value list>]

For job-specific now reservations:

pbs_rsub [-I <block time>] --job <job ID>

For maintenance reservations:

pbs_rsub [-D <duration>] [-E <end time>] [-g <group list>] [-G <auth group list>] [-H <auth host list>] [-N <reservation name>] [-q <destination>] [-R <start time>] [-u <user list>] [-U <auth user list>] --hosts <host list>

For version information:

pbs_rsub --version

3.7.2 Description

The `pbs_rsub` command is used to create advance, standing, or maintenance reservations. For creating job-specific start reservations, see "qsub" on page 216 of the PBS Professional Reference Guide.

- An advance reservation reserves specific resources for the requested time period.
- A standing reservation reserves specific resources for recurring time periods.
- A job-specific start reservation is created immediately using a running job's resources, and the job is moved into the reservation. You create job-specific start reservations using `qsub -Wcreate_resv_from_job=true` on a running job or when you `qalter` a job to set the job's create_resv_from_job attribute to *True*. See the `qsub` command.
- A maintenance reservation reserves the specified hosts for the specified time regardless of other circumstances.

Advance, standing, and job-specific reservations are "job reservations", to distinguish them from maintenance reservations. When a reservation is created, it has an associated queue.

To get information about a reservation, use the `pbs_rstat` command.

To delete a reservation, use the `pbs_rdel` command. Do not use the `qdel` command.

3.7.2.1 Reservation Timing

Bear in mind that jobs and reservations that were created before you took the snapshot keep their dates and times, which may be in the past.

3.7.2.2 Job Reservations

After an advance or standing reservation is requested, it is either confirmed or denied. Once the reservation has been confirmed, authorized users submit jobs to the reservation's queue via `qsub` and `qmove`.

A confirmed job reservation will accept jobs at any time. The jobs in its queue can run only during the reservation period. Jobs in a single advance reservation or job-specific reservation can run only during the reservation's time slot, and jobs in a standing reservation can run only during the time slots of occurrences of the standing reservation.

When an advance reservation ends, all of its jobs are deleted, whether running or queued. When an occurrence of a standing reservation ends, only its running jobs are deleted; those jobs still in the queue are not deleted.

3.7.2.3 Maintenance Reservations

You can create maintenance reservations using `pbs_rsub --hosts <host list>`. Maintenance reservations are designed to make the specified hosts available for the specified amount of time, regardless of what else is happening:

- You can create a maintenance reservation that includes or is made up of vnodes that are down or offline.
- Maintenance reservations ignore the value of a vnode's resv_enable attribute.
- PBS immediately confirms any maintenance reservation.
- Maintenance reservations take precedence over other reservations; if you create a maintenance reservation that overlaps an advance or standing job reservation, the overlapping vnodes become unavailable to the job reservation, and the job reservation is in conflict with the maintenance reservation. PBS looks for replacement vnodes; see "Reservation Fault Tolerance" on page 401 in the PBS Professional Administrator's Guide.

PBS will not start any new jobs on vnodes overlapping or in a maintenance reservation. However, jobs that were already running on overlapping vnodes continue to run; you can let them run or requeue them.

You cannot specify place or select for a maintenance reservation; these are created by PBS:

- PBS creates the reservation's placement specification so that hosts are assigned exclusively to the reservation. The placement specification is always the following:

  -lplace=exclhost
- PBS sets the reservation's resv_nodes attribute value so that all CPUs on the reserved hosts are assigned to the maintenance reservation. The select specification is always the following:

  -lselect=host=<host1>:ncpus=<number of CPUs at host1>+host=<host2>:ncpus=<number of CPUs at host2>+...

Maintenance reservations are prefixed with *M*. A maintenance reservation ID has the format:

M<sequence number>.<server name>

You cannot create a recurring maintenance reservation.

Creating a maintenance reservation does not trigger a scheduling cycle.

You must have manager or operator privilege to create a maintenance reservation.

3.7.2.4 Requirements

When using `pbs_rsub` to request a standing, advance, or maintenance reservation, you must specify two of the following options: `-R`, `-E`, and `-D`. The resource request `-l walltime` can be used instead of the `-D` option.

If you want to run jobs in a reservation that will request exclusive placement, you must create the reservation with exclusive placement via `-l place=excl`.

3.7.3 Options to `pbs_rsub`

-D <duration>

Specifies reservation duration. If the start time and end time are the only times specified, this duration time is calculated.

Format: *Duration*

Default: none

-E <end time>

Specifies the reservation end time. If start time and duration are the only times specified, the end time value is calculated.

Format: *Datetime.*

Default: none

-g <group_list>

The *group list* is a comma-separated list of group names. The server uses entries in this list, along with an ordered set of rules, to associate a group name with the reservation. The reservation creator's primary group is automatically added to this list.

Format: *<group>@<hostname>[,<group>@<hostname> ...]*

-G <auth group list>

Comma-separated list of names of groups who can or cannot submit jobs to this reservation. Sets reservation's Authorized_Groups attribute to *auth group list*.

This list becomes the acl_groups list for the reservation's queue.

More specific entries should be listed before more general, because the list is read left-to-right, and the first match determines access.

If both the Authorized_Users and Authorized_Groups reservation attributes are set, a user must belong to both in order to be able to submit jobs to this reservation.

Group names are interpreted in the context of the server host, not the context of the host from which the job is submitted.

See the Authorized_Groups reservation attribute in section 6.8, “Reservation Attributes”, on page 303.

Syntax:

[+|-]<group name>[,[+|-]<group name> ...]

Default: No groups are authorized to submit jobs

--hosts <host list>

Space-separated list of hosts to be included in maintenance reservation. PBS creates placement and resource requests. Placement is always *exclhost*, and all CPUs of requested hosts are assigned to maintenance reservation. Cannot be used with the `-l <placement>`, `-l <resource request>`, or `-I <block time>` options.

-H <auth host list>

Comma-separated list of hosts from which jobs can and cannot be submitted to this reservation. This list becomes the acl_hosts list for the reservation's queue. More specific entries should be listed before more general, because the list is read left-to-right, and the first match determines access. If the reservation creator specifies this list, the creator's host is not automatically added to the list.

See the Authorized_Hosts reservation attribute in section 6.8, “Reservation Attributes”, on page 303.

Format: *[+|-]<hostname>[,[+|-]<hostname> ...]*

Default: All hosts are authorized to submit jobs

--job <job ID>

Immediately creates and confirms a *job-specific now reservation* on the same resources as the job (including resources inherited by the job), and places the job in the job-specific now reservation queue. Sets the job's create_resv_from_job attribute to *True*. Sets the now reservation's reserve_job attribute to the ID of the job from which the reservation was created, sets the reservation's Reserve_Owner attribute to the value of the job's Job_Owner attribute, sets the reservation's resv_nodes attribute to the job's exec_vnode attribute, sets the reservation's resources to match the job's schedselect attribute, and sets the reservation's Resource_List attribute to the job's Resource_List attribute.

The now reservation's duration and start time are the same as the job's walltime and start time. If the job is peer scheduled, the now reservation is created in the pulling complex.

Format: Boolean

Default: no default

Example:

```
pbs_rsub --job 1234.myserver
```

Can be used on running jobs only (jobs in the *R* state, with substate *42*).

Cannot be used with job arrays, jobs already in reservations, or other users' jobs.

-l <placement>

The *placement* specifies how vnodes are reserved. The place statement can contain the following elements, in any order:

-l place=[<arrangement>][:[<sharing>]][:[<grouping>]]

where

arrangement

Whether this reservation chunk is willing to share this vnode or host with other chunks from this reservation. One of *free* | *pack* | *scatter* | *vscatter*

sharing

Whether this reservation chunk is willing to share this vnode or host with other reservations or jobs. One of *excl* | *shared* | *exclhost*

grouping

Whether the chunks from this reservation should be placed on vnodes that all have the same value for a resource. Can have only one instance of *group=<resource name>*

free

Place reservation on any vnode(s).

pack

All chunks are taken from one host.

scatter

Only one chunk with any MPI processes is taken from a host. A chunk with no MPI processes may be taken from the same vnode as another chunk.

vscatter

Only one chunk is taken from any vnode. Each chunk must fit on a vnode.

excl

Only this reservation uses the vnodes chosen.

shared

This reservation can share the vnodes chosen.

exclhost

The entire host is allocated to the reservation.

group=<resource name>

Chunks are grouped according to the specified resource. All vnodes in the group must have a common value for *resource*, which can be either the built-in resource host or a custom vnode-level resource.

Resource name must be a string or a string array.

If you want to run jobs in the reservation that will request exclusive placement, you must create the reservation with exclusive placement via `-l place=excl`.

The place statement cannot start with a colon. Colons are delimiters; use them only to separate parts of a place statement, unless they are quoted inside resource values.

Note that vnodes can have sharing attributes that override reservation placement requests.

See section 6.10, “Vnode Attributes”, on page 320.

Cannot be used with `--hosts` option.

-l <resource request>

The *resource request* specifies the resources required for the reservation. These resources are used for the limits on the queue that is dynamically created for the reservation. The aggregate amount of resources for currently running jobs from this queue will not exceed these resource limits. Jobs in the queue that request more of a resource than the queue limit for that resource are not allowed to run. Also, the queue inherits the value of any resource limit set on the server, and these are used for the job if the reservation request itself is silent about that resource. A non-privileged user cannot submit a reservation requesting a custom resource which has been created to be invisible or read-only for users.

Resources are requested by using the `-l` option, either in chunks inside of selection statements, or in job-wide requests using *<resource name>=<value>* pairs.

Requesting resources in chunks:

-l select=[N:]<chunk>[+[N:]<chunk> ...]

where *N* specifies how many of that chunk, and a chunk is of the form:

<resource name>=<value>[:<resource name>=<value> ...]

Requesting job-wide resources:

-l <resource name>=<value>[,<resource name>=<value> ...]

Default: One chunk containing one CPU.

Cannot be used with `--hosts` option.

-N <reservation name>

Specifies a name for the reservation.

Format: *Reservation Name*. See "Reservation Name” on page 358.

Default: None.

-q <server>

Specifies the server at which to create the reservation.

Default: Default server

-r <recurrence rule>

Specifies rule for recurrence of standing reservations. Rule must conform to iCalendar syntax, and is specified using a subset of parameters from RFC 2445.

Valid syntax for *recurrence rule* takes one of two forms:

FREQ=<freq spec>;COUNT=<count spec>;<interval spec>

or

FREQ=<freq spec>;UNTIL=<until spec>;<interval spec>

where

freq spec

Frequency with which the standing reservation repeats. Valid values are:

WEEKLY|DAILY|HOURLY

count spec

The exact number of occurrences. Number up to 4 digits in length.

Format: *Integer*.

interval spec

Specifies interval. Format is one or both of:

BYDAY=MO|TU|WE|TH|FR|SA|SU

or

BYHOUR=0|1|2|...|23

When using both, separate them with a semicolon.

Elements specified in the recurrence rule override those specified in the arguments to the -R and -E options. For example, the BYHOUR specification overrides the hourly part of the -R option. For example, `-R 0730 -E 0830 ... BYHOUR=9` results in a reservation that starts at 9:30 and runs for 1 hour.

until spec

Occurrences will start up to but not after date and time specified. Format:

<YYYYMMDD>[T<HHMMSS>]

Note that the year-month-day section is separated from the hour-minute-second section by a capital T.

Requirements:

- The recurrence rule must be on one unbroken line and must be enclosed in double quotes.
- A start and end date must be used when specifying a recurrence rule. See the `R` and `E` options.
- The PBS_TZID environment variable must be set at the submission host. The format for PBS_TZID is a timezone location. Examples: `America/Los_Angeles, America/Detroit, Europe/Berlin, Asia/Calcutta`. See the PBS Professional User's Guide.
- Spaces are not allowed.

Examples of Standing Reservations

For a reservation that runs every day from 8am to 10am, for a total of 10 occurrences:

```
pbs_rsub -R 0800 -E 1000 -r "FREQ=DAILY;COUNT=10"
```

Every weekday from 6am to 6pm until December 10 2008

```
pbs_rsub -R 0600 -E 1800 -r "FREQ=WEEKLY;BYDAY=MO,TU,WE,TH,FR;UNTIL=20081210"
```

Every week from 3pm to 5pm on Monday, Wednesday, and Friday, for 9 occurrences, i.e., for three weeks:

```
pbs_rsub -R 1500 -E 1700 -r "FREQ=WEEKLY;BYDAY=MO,WE,FR;COUNT=3"
```

-R <start time>

Specifies reservation starting time. If the reservation's end time and duration are the only times specified, this start time is calculated.

If the day, *DD*, is not specified, it defaults to today if the time *hhmm* is in the future. Otherwise, the day is set to tomorrow. For example, if you submit a reservation with the specification `-R 1110` at 11:15 a.m., it is interpreted as being for 11:10am tomorrow. If the month portion, *MM*, is not specified, it defaults to the current month, provided that the specified day *DD*, is in the future. Otherwise, the month is set to next month. Similar rules apply to the two other optional, left-side components.

Format: *Datetime*

-u <user list>

Not used. Comma-separated list of user names.

Format: *<username>[@<hostname>][,<username>[@<hostname>] ...]*

Default: None.

-U <auth user list>

Comma-separated list of users who are and are not allowed to submit jobs to this reservation. Sets reservation's Authorized_Users attribute to *auth user list*.

This list becomes the acl_users attribute for the reservation's queue.

More specific entries should be listed before more general, because the list is read left-to-right, and the first match determines access. The reservation creator's username is automatically added to this list, whether or not the reservation creator specifies this list.

If both the Authorized_Users and Authorized_Groups reservation attributes are set, a user must belong to both in order to be able to submit jobs to this reservation.

See the Authorized_Users reservation attribute in "Reservation Attributes" on page 303 of the PBS Professional Reference Guide.

Syntax:

[+|-]<username>[@<hostname>][,[+|-]<username>[@<hostname>]...]

Default: Job owner only.

-W <extended options>

This allows you to define other attributes for the reservation or perform other actions.

delete_idle_time=<allowed idle time>

Deletes the reservation after the specified amount of idle time. Applies to each instance of a standing reservation.

--version

The `pbs_rsub` command returns its PBS version information and exits. This option can only be used alone.

3.7.4 Output

The `pbs_rsub` command returns the reservation identifier.

Format for an advance or job-specific reservation:

R<sequence number>.<server name>

The associated queue's name is the prefix, *R<sequence number>*.

Format for a standing reservation:

S<sequence number>.<server name>

The associated queue's name is the prefix, *S<sequence number>*.

Format for a maintenance reservation:

M<sequence number>.<server name>

3.7.5 See Also

3.8 pbs_snapshot

Linux only. Captures PBS workload and configuration data

3.8.1 Synopsis

pbs_snapshot -h, --help

pbs_snapshot -o <output directory path> [--accounting-logs=<number of days>] [--additional-hosts=<hostname list>] [--basic] [--config-only] [--daemon-logs=<number of days>] [-H <server host>] [-l <log level>] [--map=<file path>] [--obfuscate] [--with-sudo]

pbs_snapshot [--obf-snap <path to snapshot>]

pbs_snapshot --version

3.8.2 Description

You use `pbs_snapshot` to capture PBS workload and configuration data. This tool is written in Python and uses PTL libraries, including `PBSSnapUtils`, to extract the data. You can optionally anonymize the PBS data during or after capturing it. The `pbs_snapshot` command captures data from all multischeds. The command detects which daemon or daemons are running on the host where it is collecting information, and captures daemon and system data accordingly. If no PBS daemons are running, the command collects system information. The output tarball contains information about the host specified via the `-H` option, or if that is not specified, the local host. If you specify additional hosts, the command creates a tarball for each additional host and includes it as a sub-tarball in the output.

- To supply information for simulation that you will use to tune your site, capture standard PBS configuration and node information via the `--basic` option.
- To supply information to PBS Cloud, capture PBS configuration file information via the `--config-only` option.
- For debugging your site, capture everything via the default behavior (do not specify `--basic` or `--config-only`).

3.8.2.1 Required Privilege

The `pbs_snapshot` command allows you to use the `sudo` infrastructure provided by the PTL framework to capture root-owned information via `--with-sudo`. All other information is collected as a normal user. If you need to run `pbs_snapshot` as a non-privileged user, and without using the PTL `--with-sudo` infrastructure, you must be root if you want root-owned information to be collected.

3.8.2.2 Restrictions

The `pbs_snapshot` command is not available on Windows.

3.8.3 Options to pbs_snapshot

--accounting-logs=<number of days>

Specifies number of days of accounting logs to be collected; this count includes the current day.

Value of *number of days* must be >=0:

- If number of days is 0, no logs are captured.
- If number of days is 1, only the logs for the current day are captured.

Default: `pbs_snapshot` collects 30 days of accounting logs

--additional-hosts=<hostname list>

Specifies that `pbs_snapshot` should gather data from the specified list of additional hosts. Launches the `pbs_snapshot` command on each specified host, creates a tarball there named *<hostname>_snapshot.tgz*, and includes it as a sub-tarball in the output for the main output. If you use the `--with-sudo` option, each launched copy uses that option as well.

The command does not query the server when it runs at a non-server host.

The command collects a full snapshot, including the following information:

- Daemon logs, for the number of days of logs being captured, specified via the `--daemon-logs=<number of days>` option
- The `PBS_HOME/<daemon>_priv` directory
- Accounting logs if server daemon runs on host
- System information

Format for *hostname list* is a comma-separated list of one or more hostnames:

<hostname>[, <hostname> ...]

--basic

Captures basic PBS configuration and node information only. Captures the following:

Table 3-4: PBS Configuration Information Captured with --basic Option

Directory or File	Output File	Description of Captured Information
pbs.conf		Copy of /etc/pbs.conf on server host
server	qstat_Bf.out	Output of qstat -Bf
	qstat_Qf.out	Output of qstat -Qf
server_priv	resourcedef	Copy of server_priv/resourcedef file
	config	Copy of server_priv/config file
scheduler	qmgr_lsched.out	Output of qmgr -c 'list sched'
sched_priv for each scheduler instance	sched_priv	Copy of each scheduler's sched_priv directory
hook	qmgr_lpbshook.out	Output of qmgr -c 'list pbshook'
	qmgr_ph_default.out	Output of qmgr -c 'print hook @default'
mom_priv on server host only, if it exists	config on server host only, if it exists	Copy of mom_priv/config file
node	pbsnodes_va.out	Output of pbsnodes -va
reservation	pbs_rstat_f.out	Output of pbs_rstat -f
job	qstat_f.out	Output of qstat -f
system	os_info	OS information
	pbs_environment	Copy of pbs_environment file
pbs_snapshot.log		Log of pbs_snapshot execution
ctime		Timestamp of when the snapshot was taken

Can be combined with other options such as --accounting_logs and --daemon_logs in order to capture additional information.

We also list the contents in section 3.8.4.2, “Output Contents”, on page 45.

--config-only

Captures PBS configuration file information only. Captures the following:

Table 3-5: PBS Configuration Information Captured with --config-only Option

Directory or File	Output File	Description of Captured Information
pbs.conf		Copy of /etc/pbs.conf on server host
server	qstat_Bf.out	Output of qstat -Bf
	qstat_Qf.out	Output of qstat -Qf
server_priv	resourcedef	Copy of server_priv/resourcedef file
	config	Copy of server_priv/config file
scheduler	qmgr_lsched.out	Output of qmgr -c 'list sched'
sched_priv for each scheduler instance	dedicated_time	Copy of dedicated_time file
	holidays	Copy of holidays file
	resource_group	Copy of resource_group file
	sched_config	Copy of sched_config file
hook	qmgr_lpbshook.out	Output of qmgr -c 'list pbshook'
	qmgr_ph_default.out	Output of qmgr -c 'print hook @default'
mom_priv only for server host, if it exists	config on server host only, if it exists	Copy of mom_priv/config file
system	os_info	OS information
	pbs_environment	Copy of pbs_environment file
pbs_snapshot.log		Log of pbs_snapshot execution
ctime		Timestamp of when the snapshot was taken

Can be combined with other options such as --accounting-logs and --daemon-logs in order to capture additional information.

We also list the contents in section 3.8.4.2, “Output Contents”, on page 45.

--daemon-logs=<number of days>

Specifies number of days of daemon logs to be collected; this count includes the current day.

Value of *number of days* must be >=0:

- If number of days is 0, no logs are captured.
- If number of days is 1, only the logs for the current day are captured.

Default: pbs_snapshot collects 5 days of daemon logs

-h, --help

Prints usage and exits.

-H <hostname>

Specifies hostname for host whose retrieved data is to be at the top level in the output tarball. If not specified, pbs_snapshot puts data for the local host at the top level in the output tarball.

-l <log level>

Specifies level at which pbs_snapshot writes its log. The log file is pbs_snapshot.log, in the output directory path specified using the -o <output directory path> option.

Valid values, from most comprehensive to least: *DEBUG2, DEBUG, INFOCLI2*, *INFOCLI, INFO*, *WARNING*, *ERROR*, *FATAL*

Default: *INFOCLI2*

--map=<file path>

Specifies path for file containing obfuscation map, which is a <key>:<value> pair-mapping of obfuscated data. Path can be absolute or relative to current working directory.

Default: pbs_snapshot writes its obfuscation map in a file called "obfuscate.map" in the location specified via the -o <output directory path> option.

Can only be used with the --obfuscate option.

-o <output directory path>

Path to directory where pbs_snapshot writes its output tarball. Required. Path can be absolute or relative to current working directory.

For example, if you specify "-o /tmp", pbs_snapshot writes "/tmp/snapshot_<timestamp>.tgz".

The output directory path must already exist.

--obfuscate

Obfuscates (anonymizes) or deletes sensitive PBS data being captured by pbs_snapshot.

- Obfuscates the following data: euser, egroup, project, Account_Name, operators, managers, group_list, Mail_Users, User_List, server_host, acl_groups, acl_users, acl_resv_groups, acl_resv_users, sched_host, acl_resv_hosts, acl_hosts, Job_Owner, exec_host, Host, Mom, resources_available.host, resources_available.vnode
- Deletes the following data: Variable_List, Error_Path, Output_Path, mail_from, Mail_Points, Job_Name, jobdir, Submit_arguments, Shell_Path_List

--obf-snap <path to snapshot>

Obfuscates (anonymizes) or deletes sensitive PBS data already captured in an existing snapshot. Path can be a snapshot .tar file previously generated by pbs_snapshot, or a directory created by untarring a snapshot. Obfuscated snapshot is created with the name "<directory or original snapshot>_obf.tgz".

- Obfuscates the following data: euser, egroup, project, Account_Name, operators, managers, group_list, Mail_Users, User_List, server_host, acl_groups, acl_users, acl_resv_groups, acl_resv_users, sched_host, acl_resv_hosts, acl_hosts, Job_Owner, exec_host, Host, Mom, resources_available.host, resources_available.vnode
- Deletes the following data: Variable_List, Error_Path, Output_Path, mail_from, Mail_Points, Job_Name, jobdir, Submit_arguments, Shell_Path_List

If the snapshot contains snapshots of multiple hosts, each snapshot must be obfuscated individually.

--version

The pbs_snapshot command prints its PBS version information and exits. Can only be used alone.

--with-sudo

Uses the PTL sudo infrastructure in order capture root-owned information via sudo. (Information not owned by root is captured using normal privilege, not root privilege.) With this option, you do not need to prefix your pbs_snapshot command with sudo, and you do not need root privilege.

3.8.4 Output

3.8.4.1 Output Location

You must use the `-o <output directory path>` option to specify the directory where `pbs_snapshot` writes its output. The path can be absolute or relative to current working directory. The output directory must already exist. As an example, if you specify "`-o /tmp`", `pbs_snapshot` writes "`/tmp/snapshot_<timestamp>.tgz`".

3.8.4.2 Output Contents

The `pbs_snapshot` command writes the output for the local host and each specified remote host as a tarball. Tarballs for remote hosts are included in the main tarball.

The command captures JSON output from `qstat -f -F json` and `pbsnodes -av -F json`.

The main tarball contains the following directory structure, files, and tarballs, and lists which of those elements appear in a tarball produced by the --basic and --config-only options:

Table 3-6: Contents of Snapshot

Directory or File	Directory Contents	Description	In Basic	In Config Only
server/	qstat_B.out	Output of `qstat -B`		
	qstat_Bf.out	Output of `qstat -Bf`	Yes	Yes
	qmgr_ps.out	Output of `qmgr print server`		
	qstat_Q.out	Output of `qstat -Q`		
	qstat_Qf.out	Output of `qstat -Qf`	Yes	Yes
	qmgr_pr.out	Output of `qmgr print resource`		
server_priv/	Copy of the `PBS_HOME/server_priv` directory. Core files are captured separately; see `core_file_bt/`.		`resourcedef`	`resourcedef` `config`
	accounting/	Accounting logs from `PBS_HOME/server_priv/accounting/` directory for the number of days specified via `--accounting-logs` option		
server_logs/	Server logs from the `PBS_HOME/server_logs` directory for the number of days specified via `--daemon-logs` option			

Table 3-6: Contents of Snapshot

Directory or File	Directory Contents	Description	In Basic	In Config Only
job/	qstat.out	Output of qstat		
	qstat_f.out	Output of qstat -f	Yes	
	qstat_f_F_json.out	Output of qstat -f -F json		
	qstat_t.out	Output of qstat -t		
	qstat_tf.out	Output of qstat -tf		
	qstat_x.out	Output of qstat -x		
	qstat_xf.out	Output of qstat -xf		
	qstat_ns.out	Output of qstat -ns		
	qstat_fx_F_dsv.out	Output of qstat -fx -F dsv		
	qstat_f_F_dsv.out	Output of qstat -f -F dsv		
node/	pbsnodes_va.out	Output of pbsnodes -va	Yes	
	pbsnodes_a.out	Output of pbsnodes -a		
	pbsnodes_avSj.out	Output of pbsnodes -avSj		
	pbsnodes_aSj.out	Output of pbsnodes -aSj		
	pbsnodes_avS.out	Output of pbsnodes -avS		
	pbsnodes_aS.out	Output of pbsnodes -aS		
	pbsnodes_aFdsv.out	Output of pbsnodes -aF dsv		
	pbsnodes_avFdsv.out	Output of pbsnodes -avF dsv		
	pbsnodes_avFjson.out	Output of pbsnodes -avF json		
	qmgr_pn_default.out	Output of qmgr print node @default		
mom_priv/	Copy of the PBS_HOME/mom_priv directory. Core files are captured separately; see core_file_bt/.			mom_priv/config, only from server host
mom_logs/	MoM logs from the PBS_HOME/mom_logs directory for the number of days specified via --daemon-logs option			
comm_logs/	Comm logs from the PBS_HOME/comm_logs directory for the number of days specified via --daemon-logs option			
sched_priv/	Copy of the PBS_HOME/sched_priv directory, with all files. Core files are not captured; see core_file_bt/.		Yes	
sched_logs/	Scheduler logs from the PBS_HOME/sched_log directory. For a snapshot of a live PBS complex, this is for the number of days specified via pbs_snapshot --daemon-logs. For a simulation output snapshot, this is for the time simulated via simsh <path to snapshot> sim -L.			

Table 3-6: Contents of Snapshot

Directory or File	Directory Contents	Description	In Basic	In Config Only
sched_priv_<multisched name>/	Copy of the PBS_HOME/sched_priv_<multisched name> directory, with all files. Core files are not captured; see core_file_bt/.		Yes	dedicated_time holidays resource_group sched_config
sched_logs_<multisched name>/	Multisched logs from the PBS_HOME/sched_log_<multisched name> directory for the number of days specified via --daemon-logs option			
reservation/	pbs_rstat_f.out	Output of pbs_rstat -f	Yes	
	pbs_rstat.out	Output of pbs_rstat		
scheduler/	qmgr_lsched.out	Output of qmgr list sched	Yes	Yes
hook/	qmgr_ph_default.out	Output of qmgr -c 'print hook @default'		Yes
	qmgr_lpbshook.out	Output of qmgr -c 'list pbshook'	Yes	Yes
datastore/	pg_log/	Copy of the PBS_HOME/datastore/pg_log directory for the number of days specified via --daemon-logs option		

Table 3-6: Contents of Snapshot

Directory or File	Directory Contents	Description	In Basic	In Config Only
core_file_bt/	Stack backtrace from core files			
	sched_priv/	Files containing the output of `thread apply all backtrace full` on all core files captured from PBS_HOME/sched_priv		
	sched_priv_<multi-sched name>	Files containing the output of `thread apply all backtrace full` on all core files captured from PBS_HOME/sched_priv_<multisched name>		
	server_priv/	Files containing the output of `thread apply all backtrace full` on all core files captured from PBS_HOME/server_priv		
	mom_priv/	Files containing the output of `thread apply all backtrace full` on all core files captured from PBS_HOME/mom_priv		
	misc/	Files containing the output of `thread apply all backtrace full` on any other core files found inside PBS_HOME		

Table 3-6: Contents of Snapshot

Directory or File	Directory Contents	Description	In Basic	In Config Only
system/	pbs_probe_v.out	Output of `pbs_probe -v`		
	pbs_hostn_v.out	Output of `pbs_hostn -v $(hostname)`		
	pbs_environment	Copy of PBS_HOME/pbs_environment file		Yes
	os_info	Information about the OS		Yes
	process_info	List of processes running on the system when the snapshot was taken. Output of `ps -aux | grep [p]bs` on Linux systems, or `tasklist /v` on Windows systems		
	ps_leaf.out	Output of `ps -leaf`. Linux only.		
	lsof_pbs.out	Output of `lsof | grep [p]bs`. Linux only.		
	etc_hosts	Copy of /etc/hosts file. Linux only.		
	etc_nsswitch_conf	Copy of /etc/nsswitch.conf file. Linux only.		
	vmstat.out	Output of the command `vmstat`. Linux only.		
	df_h.out	Output of the command `df -h`. Linux only.		
	dmesg.out	Output of the `dmesg` command. Linux only.		
pbs.conf	Copy of the pbs.conf file on the server host		Yes	Yes
ctime	Contains the time in seconds since epoch when the snapshot was taken		Yes	Yes
pbs_snapshot.log	Log messages written by `pbs_snapshot`		Yes	Yes
<remote hostname>.tgz	Tarball of output from running the `pbs_snapshot` command at a remote host			

3.8.5 Examples

`pbs_snapshot -o /tmp`

Writes a snapshot to /tmp/snapshot_<timestamp>.tgz that includes 30 days of accounting logs and 5 days of daemon logs from the server host.

`pbs_snapshot --daemon-logs=1 --accounting-logs=1 -o /tmp --obfuscate --map=mapfile.txt`

Writes a snapshot to /tmp/snapshot_<timestamp>.tgz that includes 1 day of accounting and daemon logs. Obfuscates the data and stores the data mapping in the map file named "mapfile.txt".

3.9 pbs_stat

Displays information about workload and complex

3.9.1 Synopsis

pbs_stat --eval-formula

pbs_stat [-j] [-n] [-S]

pbs_stat [-r <resource list>] -U

3.9.2 Description

The `pbs_stat` command shows information about your workload and your complex.

3.9.3 Options to pbs_stat

--eval-formula

Compute the execution priority for each job, and display the jobs in priority order along with their priorities and the contribution made by each element in the formula. To see the order in which jobs would run:

simsh <path to snapshot> pbs_stat --eval-formula

See "Using a Formula for Computing Job Execution Priority" on page 150 in the PBS Professional Administrator's Guide.

-j

Report job equivalence classes. Lists the number of jobs in each class, and the resources and queue that define the class.

To look for job equivalence classes in your workload:

pbs_stat -j

-n

Report node equivalence classes. Lists the number of nodes in each class, and the resources available on each class of node.

To look for node equivalence classes in your complex in order to check whether jobs can run:

pbs_stat -n

-r <resource list>

Used with the `-U` option. Specify which resources are listed when showing utilization via the `-U` option. Replaces default resource listing.

Format: comma-separated list of resource names

Default: ncpus, mem, and count of nodes allocated to the job

-S

List jobs in the order in which they ran, with start and end times for each job. Also shows which jobs never ran.

To see the order in which jobs ran, along with their start and end times:

pbs_stat -S

-U

Show current utilization of resources.

Default resources listed are ncpus, mem, and count of nodes allocated to jobs.

To change which resources are listed, use the `-r` option to specify a comma-separated list of resources to display.

--version

The command returns its version information and exits. This option can only be used alone.

3.10 qdel

Deletes PBS jobs

3.10.1 Synopsis

qdel [-x] <job ID> [<job ID> ...]

qdel --version

3.10.2 Description

The `qdel` command deletes jobs in the order given, whether they are at the local server or at a remote server.

3.10.2.1 Usage

The `qdel` command is used without options to delete queued, running, held, or suspended jobs, while the `-x` option gives it the additional capacity to delete finished or moved jobs. With the `-x` option, this command can be used on finished and moved jobs, in addition to queued, running, held, or suspended jobs.

When this command is used without the `-x` option, if job history is enabled, the deleted job's history is retained. The -x option is used to additionally remove the history of the job being deleted.

3.10.2.2 Sequence of Events

1. The job's running processes are killed.
2. The epilogue runs.
3. Files that were staged in are staged out. This includes standard out (.o) and standard error (.e) files.
4. Files that were staged in or out are deleted.
5. The job's temp directory is removed.
6. The job is removed from the MoM(s) and the server.

3.10.3 Options to `qdel`

(no options)
: Can delete queued, running, held, or suspended jobs. Does not delete job history for specified job(s).

-x
: Can delete running, queued, suspended, held, finished, or moved jobs. Deletes job history for the specified job(s).

--version
: The `qdel` command returns its PBS version information and exits. This option can only be used alone.

3.10.4 Operands

The `qdel` command accepts one or more space-separated *job ID* operands. These operands can be job identifiers, job array identifiers, subjob identifiers, or subjob range identifiers.

Job IDs have the form:

<sequence number>[.<server name>][@<server name>]

Job arrays have the form:

<sequence number>[][.<server name>][@<server name>]

Subjobs have the form:

<sequence number>[<index>][.<server name>][@<server name>]

Ranges of subjobs have the form:

<sequence number>[<first>-<last>][.<server name>][@<server name>]

Job array identifiers must be enclosed in double quotes for some shells.

3.10.5 Standard Error

The `qdel` command writes a diagnostic message to standard error for each error occurrence.

3.10.6 Exit Status

Zero
: Upon successful processing of input

Greater than zero
: Upon error

3.11 qmgr

Administrator's command interface for managing PBS

3.11.1 Synopsis

At shell command line:

qmgr -c '<directive> [-a] [-e] [-n] [-z]'

qmgr -c 'help [<help option>]'

qmgr --version

3.11.2 Description

The PBS manager command, `qmgr`, provides a command-line interface to parts of PBS. The `qmgr` command is used to create or delete queues, vnodes, and resources, to set or change vnode, queue, server, or scheduler attributes and resources, and to view information about queues, vnodes, resource definitions, the server, and schedulers.

For a list of quick summaries of information about syntax, commands, attributes, operators, names, and values, type "`help`" or "`?`" at the `qmgr` prompt. See section 3.11.9, “Printing Usage Information”, on page 70.

3.11.2.1 Mode of Operation

When you type `qmgr -c '<directive>'`, `qmgr` performs its task and then exits.

3.11.3 Options to `qmgr`

The following table lists the options to `qmgr`:

Table 3-7: `qmgr` Options

Option	Action
`-a`	Aborts `qmgr` on any syntax errors or any requests rejected by a server.
`-c '<directive>'`	Executes a single command (*directive*) and exit `qmgr`. The *directive* must be enclosed in single or double quote marks, for example: `qmgr -c "print server"`
`-c 'help [<help option>]'`	Prints out usage information. See "Printing Usage Information” on page 70
`-e`	Echoes all commands to standard output
`-n`	No commands are executed; syntax checking only is performed
`-z`	No errors are written to standard error
`--version`	The `qmgr` command returns its PBS version information and exits. This option can only be used alone

3.11.4 Directives

A `qmgr` *directive* is a *command* together with the *object(s)* to be operated on, the *attribute(s)* belonging to the object that is to be changed, the *operator*, and the *value(s)* the *attribute(s)* will take. In the case of resources, you can set the *type* and/or *flag*(s).

3.11.4.1 Directive Syntax

A directive is terminated by a newline or a semicolon (";"). Multiple directives may be entered on a single line. A directive may extend across lines by escaping the newline with a backslash ("\").

Comments begin with the "#" character and continue to the end of the line. Comments and blank lines are ignored by `qmgr`.

3.11.4.1.i Server, Scheduler, Queue, Vnode Directives

Syntax for operating on servers, schedulers, queues, and vnodes:

<command> <object type> [<object name(s)>] [<attribute> <operator> <value>[,<attribute> <operator> <value>,...]]

For information about attributes, see Chapter 6, "Attributes", on page 277.

3.11.4.1.ii Resource Directives

Syntax for operating on resources:

<command> <resource name> [<resource name> ...] [type = <type>][,flag = <flag(s)>]

For information about resources, see "Using PBS Resources" on page 227 in the PBS Professional Administrator's Guide and Chapter 5, "List of Built-in Resources", on page 259.

3.11.4.2 Using Directives

To use a directive from the command line, enclose the command and its arguments in single or double quotes.

qmgr -c '<command> <command arguments>'

For example, to have `qmgr` print server information and exit:

```
qmgr -c "print server"
```

3.11.4.3 Commands Used in Directives

Commands can be abbreviated to their minimum unambiguous form. Commands apply to all target objects unless explicitly limited. The following table lists the commands, briefly tells what they do, and gives a link to a full description:

Table 3-8: `qmgr` Commands Used in Directives

Command	Abbr.	Effect	Description
`active`	`a`	Specifies active objects	See section 3.11.6.1, "Making Objects Active", on page 59
`create`	`c`	Creates object	See section 3.11.6.2, "Creating Objects (Server, Scheduler, Vnode, Queue)", on page 60
`delete`	`d`	Deletes object	See section 3.11.6.3, "Deleting Objects", on page 61

Table 3-8: `qmgr` Commands Used in Directives

Command	Abbr.	Effect	Description
`exit`		Exits (quits) the `qmgr` session	
`help or ?`	`h, ?`	Prints usage to `stdout`	See section 3.11.9, "Printing Usage Information", on page 70
`list`	`l`	Lists object attributes and their values	See section 3.11.8.1, "Listing Objects and Their Attributes", on page 68
`print`	`p`	Prints creation and configuration commands	See section 3.11.8.3, "Printing Creation and Configuration Commands", on page 69
`quit`	`q`	Quits (exits) the `qmgr` session	
`set`	`s`	Sets value of attribute	See section 3.11.7.1, "Setting Attribute and Resource Values", on page 62
`unset`	`u`	Unsets value of attribute	See section 3.11.7.2, "Unsetting Attribute and Resource Values", on page 62

3.11.5 Arguments to Directive Commands

3.11.5.1 Object Arguments to Directive Commands

The `qmgr` command can operate on objects (servers, schedulers, queues, vnodes, and resources). Each of these can be abbreviated inside a directive. The following table lists the objects and their abbreviations:

Table 3-9: `qmgr` Objects

Object Name	Abbr.	Object	Can Be Created/Deleted By:	Can Be Modified By:
server	*s*	server	No one (created at installation)	Administrator, Operator, Manager
sched	*sc*	default scheduler	No one (created at installation)	Administrator, Operator, Manager
		multisched	Administrator, Manager	Administrator, Operator, Manager
queue	*q*	queue	Administrator, Operator, Manager	Administrator, Operator, Manager
node	*n*	vnode	Administrator, Operator, Manager	Administrator, Operator, Manager
resource	*r*	resource	Administrator, Manager	Administrator, Manager

3.11.5.1.i Specifying Active Server

The `qmgr` command operates on objects (queues, vnodes, etc.) at the active server. There is always at least one active server; the default server is the active server unless other servers have been made active. The default server is the server managing the host where the `qmgr` command runs, meaning it is the server specified in that host's `pbs.conf` file. Server names have the following format:

<hostname>[:<port number>]

where *hostname* is the fully-qualified domain name of the host on which the server is running and *port number* is the port number to which to connect. If *port number* is not specified, the default port number, *15001*, is used.

- To specify the default server:

  @default
- To specify a named server:

  @<server name>
- To specify all active servers:

  @active

3.11.5.1.ii Using Lists of Object Names

In a `qmgr` directive, *object name(s)* is a list of one or more names of specific objects. The administrator specifies the name of an object when creating the object. The name list is in the form:

<object name>[@<server>][,<object name>[@<server>] ...]

where *server* is replaced in the directive with "*default*", "*active*", or the name of the server. The name list must conform to the following:

- There must be no space between the object name and the @ sign.
- Name lists must not contain white space between entries.
- All objects in a list must be of the same type.
- Node attributes cannot be used as vnode names.

3.11.5.1.iii Specifying Object Type and Name

You can specify objects in the following ways:

- To act on the active objects of the named type, at the active server:

  <object type>

  For example, to list all active vnodes, along with their attributes, at the active server:

  `Qmgr: list node`
- To act on the active objects of the named type, at a specified server:

  <object type> @<server name> (note space before @ sign)

  For example, to list all active vnodes at the default server, along with their attributes:

  `Qmgr: list node @default`

  For example, to print out all queues at the default server, along with their attributes:

  `qmgr -c "print queue @default"`
- To act on a specific named object:

  <object type> <object name>

  For example, to list Node1 and its attributes:

  `Qmgr: list node Node1`

  To list queues workq, slowq, and fastq at the active server:

  `Qmgr: list queue workq,slowq,fastq`
- To act on the named object at the specified server:

  <object type> <object name>@<server name>

  For example, to list Node1 at the default server, along with the attributes of Node1:

  `Qmgr: list node Node1@default`

To list queues Queue1 at the default server, Queue2 at Server2, and Queue3 at the active server:

```
Qmgr: list queue Queue1@default,Queue2@Server2,Queue3@active
```

3.11.5.2 Operators in Directive Commands

In a qmgr directive, *operator* is the operation to be performed with the attribute and its value. Operators are listed here:

Table 3-10: Operators in Directive Commands

Operator	Effect
=	Sets the value of the attribute or resource. If the attribute or resource has an existing value, the current value is replaced with the new value.
+=	Increases the current value of the attribute or resource by the amount in the new value. When used for a string array, adds the new value as another string after a comma.
-=	Decreases the current value of the attribute or resource by the specified amount. When used for a string array, removes the first matching string.

Example 3-1: Set ACL for queue Queue1 to be Group1:

```
qmgr -c "set queue acl_groups = Group1"
```

Example 3-2: Add new group to ACL for queue Queue1:

```
qmgr -c "set queue acl_groups += Group2"
```

Example 3-3: Remove new group for queue Queue1:

```
qmgr -c "set queue acl_groups -= Group2"
```

When setting numerical resource values, you can use only the equal sign ("=").

3.11.5.3 Windows Requirements For Directive Arguments

Under Windows, use double quotes when specifying arguments to qmgr.

3.11.6 Operating on Objects (Server, Scheduler, Vnode, Queue)

3.11.6.1 Making Objects Active

Making objects active is a way to set up a list of objects, all of the same type, on which you can then use a single command. For example, if you are going to set the same attribute to the same value on several vnodes, you can make all of the target vnodes active before using a single command to set the attribute value, instead of having to give the command once for each vnode. You can make any type of object active except for resources.

When an object is active, it is acted upon when you specify its type but do not specify names. When you specify any object names in a directive, active objects are not operated on unless they are named in the directive.

You can specify a list of active objects for each type of object. You can have active objects of multiple types at the same time. The active objects of one type have no effect on whether objects of another type are active.

Objects are active only until the qmgr command is exited, so this feature can be used only at the qmgr prompt.

Each time you make any objects active at a given server, that list of objects replaces any active objects of the same kind at that server. For example, if you have four queues at a particular server, and you make Q1 and Q2 active, then later make Q3 and Q4 active, the result is that Q3 and Q4 are the only active queues.

You can make different objects be active at different servers simultaneously. For example, you can set vnodes N1 and N2 at the default server, and vnodes N3 and N4 at server Server2 to be active at the same time.

To make all objects inactive, quit `qmgr`. When you quit `qmgr`, any object that was active is no longer active.

3.11.6.1.i Using the `active` Command

- To make the named object(s) of the specified type active:

  active <object type> [<object name>[,<object name> ...]]

  Example: To make queue Queue1 active:

  ```
  qmgr -c "active queue Queue1"
  ```

  Example: To make queues Queue1 and Queue2 at the active server be active, then enable them:

  ```
  qmgr -c "active queue Queue1,Queue2"
  qmgr -c "set queue enabled=True"
  ```

  Example: To make queue Queue1 at the default server and queue Queue2 at Server2 be active:

  ```
  qmgr -c "active queue Queue1@default,Queue2@Server2"
  ```

  Example: To make vnodes N1, N2, N3, and N4 active, and then give them all the same value for their max_running attribute:

  ```
  qmgr -c "active node N1,N2,N3,N4"
  qmgr -c "set node max_running = 2"
  ```

- To make all object(s) of the specified type at the specified server active:

  active <object type> @<server name> (note space before @ sign)

  Example: To make all queues at the default server active:

  ```
  qmgr -c "active queue @default"
  ```

  Example: To make all vnodes at server Server2 active:

  ```
  qmgr -c "active node @Server2"
  ```

- To report which objects of the specified type are active:

  active <object type>

  The `qmgr` command prints a list of names of active objects of the specified type to `stdout`.

3.11.6.2 Creating Objects (Server, Scheduler, Vnode, Queue)

- To create one new object of the specified type for each name, and give it the specified name:

  create <object type> <object name>[,<object name> ...] [[<attribute> = <value>] [,<attribute> = <value>] ...]

  Can be used only with multischeds, queues, vnodes, and resources.

  For example, to create a multisched named multisched_1 at the active server:

  ```
  qmgr -c "create sched multisched_1"
  ```

  For example, to create a queue named Q1 at the active server:

  ```
  qmgr -c "create queue Q1"
  ```

  For example, to create a vnode named N1 and a vnode named N2:

  ```
  qmgr -c "create node N1,N2"
  ```

  For example, to create queue Queue1 at the default server and queue Queue2 at Server2:

  ```
  qmgr -c "create queue Queue1@default,Queue2@Server2"
  ```

For example, to create vnodes named N1, N2, N3, and N4 at the active server, and to set their Mom attribute to *Host1* and their max_running attribute to *1*:

```
qmgr -c "create node N1,N2,N3,N4 Mom=Host1, max_running = 1"
```

All objects of the same type at a server must have unique names. For example, each queue at server Server1 must have a unique name. Objects at one server can have the same name as objects at another server.

You can create multiple objects of the same type with a single command. You cannot create multiple types of objects in a single command.

To create multiple resources of the same type and flag, separate each resource name with a comma:

```
qmgr -c "create resource <resource>[,<resource> ...] type=<type>,flag=<flag(s)>"
```

3.11.6.2.i Examples of Creating Objects

Example 3-4: Create queue:

```
create queue fast priority=10,queue_type=e,enabled = true,max_running=0
```

Example 3-5: Create queue, set resources:

```
qmgr -c "create queue little"
qmgr -c "set queue little resources_max.mem=8mw,resources_max.cput=10"
```

3.11.6.3 Deleting Objects

- To delete the named object(s):

  delete <object type> <object name>[,<object name> ...]

  When you delete more than one object, do not put a space after a comma.

  Can be used only with queues, vnodes, and resources.

  For example, to delete queue Q1 at the active server:

  ```
  qmgr -c "delete queue Q1"
  ```

  For example, to delete vnodes N1 and N2 at the active server:

  ```
  qmgr -c "delete node N1,N2"
  ```

  For example, to delete queue Queue1 at the default server and queue Queue2 at Server2:

  ```
  qmgr -c "delete queue Queue1@default,Queue2@Server2"
  ```

  For example, to delete resource "foo" at the active server:

  ```
  qmgr -c "delete resource foo"
  ```

- To delete the active objects of the specified type:

  delete <object type>

  For example, to delete the active queues:

  ```
  qmgr -c "delete queue"
  ```

- To delete the active objects of the specified type at the specified server:

  delete <object type> @<server name>

  For example, to delete the active queues at server Server2:

  ```
  qmgr -c "delete queue @Server2"
  ```

You can delete multiple objects of the same type with a single command. You cannot delete multiple types of objects in a single command. To delete multiple resources, separate the resource names with commas.

For example:

```
qmgr -c "delete resource r1,r2"
```

You cannot delete a resource that is requested by a job or reservation, or that is set on a server, queue, or vnode.

3.11.7 Operating on Attributes and Resources

You can specify attributes and resources for named objects or for all objects of a type.

3.11.7.1 Setting Attribute and Resource Values

- To set the value of the specified attribute(s) for the named object(s):

  set <object type> <object name>[,<object name> ...] <attribute> = <value> [,<attribute> = <value> ...]

  Each specified attribute is set for each named object, so if you specify three attributes and two objects, both objects get all three attributes set.
- To set the attribute value for all active objects when there are active objects of the type specified:

  set <object type> <attribute> = <value>
- To set the attribute value for all active objects at the specified server when there are active objects of the type specified:

  set <object type> @<server name> <attribute> = <value>

  For example, to set the amount of memory on a vnode:

  ```
  qmgr -c "set node Vnode1 resources_available.mem = 2mb"
  ```

If the attribute is one which describes a set of resources such as resources_available, resources_default, resources_max, resources_used, etc., the attribute is specified in the form:

<attribute name>.<resource name>

You can have spaces between *attribute=value* pairs.

3.11.7.1.i Examples of Setting Attribute Values

Example 3-6: Increase limit on queue:

```
qmgr -c "set queue fast max_running +=2"
```

Example 3-7: Set software resource on mynode:

```
qmgr -c'set node mynode resources_available.software = "myapp=/tmp/foo"'
```

Example 3-8: Set limit on queue:

```
qmgr -c "set queue max_running = 10"
```

Example 3-9: Set vnode offline:

```
qmgr -c 'set node state = "offline"'
```

3.11.7.2 Unsetting Attribute and Resource Values

You can use the qmgr command to unset attributes of any object.

- To unset the value of the specified attributes of the named object(s):

  unset <object type> <object name>[,<object name> ...] <attribute>[,<attribute>...]
- To unset the value of specified attributes of active objects:

  unset <object type> <attribute>[,<attribute>...]
- To unset the value of specified attributes of the named object:

unset <object type> <object name> <attribute>[,<attribute>...]

- To unset the value of specified attributes of the named object:

  unset <object type> @<server name> <attribute>[,<attribute>...]

3.11.7.2.i Example of Unsetting Attribute Value

Example 3-10: Unset limit on queue

```
qmgr -c "unset queue fast max_running"
```

3.11.7.3 Caveats and Restrictions for Setting Attribute and Resource Values

- If the value includes whitespace, commas or other special characters, such as the # character, the value string must be enclosed in single or double quotes. For example:

  ```
  qmgr -c 'set node Vnode1 comment="Node will be taken offline Friday at 1:00 for memory upgrade."'
  ```

- You can set or unset attribute values for only one type of object in each command.
- You can use the `qmgr` command to set attributes of any object.
- You can have spaces between attribute names.
- Attribute and resource values must conform to the format for the attribute or resource type. Each attribute's type is listed in Chapter 6, "Attributes", on page 277. Each format is described in Chapter 7, "Formats", on page 353.
- Most of a vnode's attributes may be set using `qmgr`. However, some **must** be set on the individual execution host in Version 2 vnode configuration files, NOT by using `qmgr`. See "Configuring Vnodes" on page 45 in the PBS Professional Administrator's Guide.

3.11.7.4 Setting Custom Resource Type

You can use the `qmgr` command to set or unset the type for custom resources.

Resource types can be the following; see section 7.2, "Resource Formats", on page 359:

string

boolean

string_array

long

size

float

- To set a custom resource type:

  set resource <resource name> type = <type>

  Sets the type of the named resource to the specified *type*. For example:

  ```
  Qmgr: qmgr -c "set resource foo type=string_array"
  ```

3.11.7.5 Setting Custom Resource Level and Consumability

When you define a custom resource, you specify whether it is server-level or host-level, and whether it is consumable or not by setting resource accumulation flags via `qmgr`. A consumable resource is tracked, or accumulated, in the server, queue or vnode resources_assigned attribute. The resource accumulation flags determine where the value of resources_assigned.<resource name> is incremented.

3.11.7.5.i Allowable Values for Resource Accumulation Flags

The value of <*resource flags*>, which is the resource accumulation flag for a resource can be one of the following:

Table 3-11: Resource Accumulation Flags

Flag	Meaning
(no flags)	Indicates a queue-level or server-level resource that is not consumable.
fh	The amount is consumable at the host level for only the first vnode allocated to the job (vnode with first task.) Must be consumable or time-based. Cannot be used with Boolean or string resources. . This flag specifies that the resource is accumulated at the first vnode, meaning that the value of resources_assigned.<resource> is incremented only at the first vnode when a job is allocated this resource or when a reservation requesting this resource on this vnode starts.
h	Indicates a host-level resource. Used alone, means that the resource is not consumable. Required for any resource that will be used inside a select statement. This flag selects hardware. This flag indicates that the resource must be requested inside of a select statement. Example: for a Boolean resource named "green": `Qmgr: create resource green type=boolean, flag=h`
nh	The amount is consumable at the host level, for all vnodes assigned to the job. Must be consumable or time-based. Cannot be used with Boolean or string resources. This flag specifies that the resource is accumulated at the vnode level, meaning that the value of resources_assigned.<resource> is incremented at relevant vnodes when a job is allocated this resource or when a reservation requesting this resource on this vnode starts. This flag is not used with dynamic consumable resources. The scheduler will not oversubscribe dynamic consumable resources.
q	The amount is consumable at the queue and server level. When a job is assigned one unit of a resource with this flag, the resources_assigned.<resource> attribute at the server and any queue is incremented by one. Must be consumable or time-based. This flag specifies that the resource is accumulated at the queue and server level, meaning that the value of resources_assigned.<resource> is incremented at each queue and at the server when a job is allocated this resource. When a reservation starts, allocated resources are added to the server's resources_assigned attribute. This flag is not used with dynamic consumable resources. The scheduler will not oversubscribe dynamic consumable resources.

3.11.7.5.ii When to Use Accumulation Flags

The following table shows when to use accumulation flags.

Table 3-12: When to Use Accumulation Flags

Resource Category	Server	Queue	Host
Static, consumable	flag = q	flag = q	flag = nh or fh
Static, not consumable	flag = (none of h, n, q or f)	flag = (none of h, n, q or f)	flag = h
Dynamic	`server_dyn_res` line in `sched_config`, flag = (none of h, n, q or f)	(cannot be used)	Tracked using an exechost_periodic hook flag = h

3.11.7.5.iii Example of Resource Accumulation Flags

When defining a static consumable host-level resource, such as a node-locked application license, you would use the "n" and "h" flags.

When defining a dynamic resource such as a floating license, you would use no flags.

3.11.7.5.iv Resource Accumulation Flag Restrictions and Caveats

Numeric dynamic resources cannot have the q or n flags set. This would cause these resources to be under-used. These resources are tracked automatically by the scheduler.

3.11.7.6 Setting Custom Resource Visibility

When you define a custom resource, you can specify whether unprivileged users have permission to view or request the resource, and whether users can `qalter` a request for that resource. This is done by setting a resource permission flag via `qmgr`.

3.11.7.6.i Allowable Values for Resource Permission Flags

The permission flag for a resource can be one of the following:

Table 3-13: Resource Permission Flags

Flag	Meaning
(no flag)	Users can view and request the resource, and `qalter` a resource request for this resource.
i	"Invisible". Users cannot view or request the resource. Users cannot `qalter` a resource request for this resource.
r	"Read only". Users can view the resource, but cannot request it or `qalter` a resource request for this resource.

3.11.7.6.ii Effect of Resource Permission Flags

- PBS Operators and Managers can view and request a resource, and `qalter` a resource request for that resource, regardless of the i and r flags.
- Users, operators and managers cannot submit a job which requests a restricted resource. Any job requesting a restricted resource will be rejected. If a manager needs to run a job which has a restricted resource with a different value from the default value, the manager must submit the job without requesting the resource, then `qalter` the resource value.
- While users cannot request these resources, their jobs can inherit default resources from resources_default.<resource name> and default_chunk.<resource name>.

  If a user tries to request a resource or modify a resource request which has a resource permission flag, they will get an error message from the command and the request will be rejected. For example, if they try to `qalter` a job's resource request, they will see an error message similar to the following:

  ```
  "qalter: Cannot set attribute, read only or insufficient permission  Resource_List.hps 173.mars"
  ```

3.11.7.6.iii Resource Permission Flag Restrictions and Caveats

- You can specify only one of the i or r flags per resource. If both are specified, the resource is treated as if only the i flag were specified, and an error message is logged at the default log level and printed to standard error.
- Resources assigned from the default_qsub_arguments server attribute are treated as if the user requested them. A job will be rejected if it requests a resource that has a resource permission flag whether that resource was requested by the user or came from default_qsub_arguments.
- The behavior of several command-line interfaces is dependent on resource permission flags. These interfaces are those which view or request resources or modify resource requests:

  `pbsnodes`

  Users cannot view restricted host-level custom resources.

  `pbs_rstat`

  Users cannot view restricted reservation resources.

  `pbs_rsub`

  Users cannot request restricted custom resources for reservations.

  `qalter`

  Users cannot alter a restricted resource.

  `qmgr`

  Users cannot print or list a restricted resource.

  `qselect`

  Users cannot specify restricted resources via -l Resource_List.

  `qsub`

  Users cannot request a restricted resource.

  `qstat`

  Users cannot view a restricted resource.

3.11.7.7 Specifying Whether Custom Resource is Cached at MoM

You can make it faster for execution hooks to read custom job resources. Execution hooks cannot read custom job resources via the event, only via the server. However, you can cache a copy of a custom job resource at the MoMs for faster local reading by execution hooks, by setting the *m* flag for the resource. The job resources that can be cached are found in the following job attributes:

exec_vnode
Resource_List
resources_used

To create a resource with the *m* flag set, include the flag. For example, to create two host-level consumable resources r1 and r2 of type long that will be cached at MoMs:

```
qmgr -c "create resource r1,r2 type=long,flag=mnh"
```

To unset this flag for r1:

```
qmgr -c "set resource r1 flag=nh"
```

You can combine this flag with any other resource flag. Job resources created in an exechost_startup hook have the m flag set automatically.

3.11.7.7.i Caveats for Caching Custom Job Resources

Large numbers of job resources that are cached at MoMs can slow things down. If you don't need execution hooks to be able to read a custom job resource often, don't cache the resource at the MoMs.

3.11.7.7.ii Examples of Defining Custom Resources and Setting Flags via qmgr

To set the type for a resource:

set resource <resource name> type = <type>

For example:

```
qmgr -c "set resource foo type=string_array"
```

To set the flags for a resource:

set resource <resource name> flag=<flag(s)>

For example:

```
qmgr -c "set resource foo flag=nh"
```

To set the type and flags for a resource:

set resource <resource name> type=<type>, flag=<flag(s)>

For example:

```
qmgr -c "set resource foo type=long,flag=nhi"
```

You can set multiple resources by separating the names with commas. For example:

```
qmgr -c "set resource r1, r2 type=long"
```

You cannot set the *nh*, *fh*, or *q* flag for a resource of type string, string_array, or Boolean.

You cannot set both the *n* and the *f* flags on one resource.

You cannot have the *n* or *f* flags without the *h* flag.

You cannot set both the *i* and *r* flags on one resource.

You cannot unset the type for a resource.

You cannot set the type for a resource that is requested by a current or history job or reservation, or set on a server, queue, or vnode.

You cannot set the flag(s) to *h*, *nh*, *fh*, or *q* for a resource that is currently requested by a current or history job or reservation.

You cannot unset the flag(s) for a resource that is currently requested by a current or history job or a reservation, or set on any server, queue, or vnode.

You cannot alter a built-in resource.

You can unset custom resource flags, but not their type.

3.11.8 Viewing Object, Attribute, and Resource Information

3.11.8.1 Listing Objects and Their Attributes

You can use the `qmgr` command to list attributes of any object, including attributes at their default values.

- To list the attributes, with associated values, of the named object(s):

  list <object type> <object name>[,<object name> ...]
- To list values of the specified attributes of the named object:

  list <object type> <object name> <attribute name>[, <attribute name>]...
- To list attributes, with associated values, of active objects of the specified type at the active server:

  list <object type>
- To list all objects of the specified type at the specified server, with their attributes and the values associated with the attributes:

  list <object type> @<server name>
- To list attributes of the active server:

  list server

  If no server other than the default server has been made active, lists attributes of the default server (it is the active server).
- To list attributes of the specified server:

  list server <server name>
- To list attributes of all schedulers:

  list sched
- To list attributes of the specified scheduler:

  list sched <scheduler name>

3.11.8.1.i Examples of Listing Objects and Their Attributes

Example 3-11: List serverA's schedulers' attributes:

```
list sched @serverA
```

Example 3-12: List attributes for default server's scheduler(s):

```
l sched @default
```

Example 3-13: List PBS version for default server's scheduler(s):

```
l sched @default pbs_version
```

Example 3-14: List queues at a specified server:

```
list queue @server1
```

3.11.8.2 Listing Resource Definitions

You can use the `qmgr list` and `print` commands to list resource definitions showing resource name, type, and flag(s).

- To list the name, type, and flag(s) of the named resource(s):

  list resource <resource name>[,<resource name> ...]

  or

  print resource <resource name>[,<resource name> ...]
- To list name, type, and flag(s) of custom resources only:

  list resource

  or

  print resource

  or

  print server (note that this also prints information for the active server)
- To list all custom resources at the specified server, with their names, types, and flags:

  list resource @<server name>

  or

  print resource @<server name>

When used by a non-privileged user, `qmgr` prints only resource definitions for resources that are visible to non-privileged users (those that do not have the *i* flag set).

3.11.8.3 Printing Creation and Configuration Commands

For printing the creation commands for any object.

- To print out the commands to create the named object(s) and set their attributes to their current values:

  print <object type> <object name>[,<object name> ...]

  where *object name* follows the name rules in section 3.11.5.1.ii, “Using Lists of Object Names”, on page 58.
- To print out the commands to create the named object and set its attributes to their current values:

  print <object type> <object name> [<attribute name>[, <attribute name>]...]

  where *object name* follows the name rules in section 3.11.5.1.ii, “Using Lists of Object Names”, on page 58.
- To print out the commands to create and configure the active objects of the named type:

  print <object type>
- To print out the commands to create and configure all of the objects of the specified type at the specified server:

print <object type> @<server name>

- To print out the commands to create each queue, set the attributes of each queue to their current values, and set the attributes of the server to their current values:

  print server

  This is used for the server and queues.

  Prints information for the active server. If there is no active server, prints information for the default server.

- To print out the creation commands for all schedulers:

  print sched

- To print out the creation commands for the specified scheduler:

  print sched <scheduler name>

3.11.8.4 Caveats for Viewing Information

Some attributes whose values are unset do not appear in the output of the `qmgr` command.

Definitions for built-in resources do not appear in the output of the `qmgr` command.

When a non-privileged user prints resource definitions, `qmgr` prints only resource definitions for resources that are visible to non-privileged users (those that do not have the *i* flag set).

3.11.9 Printing Usage Information

You use the `help` command or a question mark ("?") to invoke the `qmgr` built-in help function. You can request usage information for any of the `qmgr` commands, and for topics including attributes, operators, names, and values.

- To print out usage information for the specified command or topic:

  qmgr -c "help [<command or topic>]"

  For example, to print usage information for the `set` command:

  ```
  qmgr -c "help set"
  Syntax: set object [name][,name...] attribute[.resource] OP value
  ```

3.11.10 Standard Input

When you start a `qmgr` session, the `qmgr` command reads standard input for directives until it reaches end-of-file, or it reads the *exit* or *quit* command.

3.11.11 Standard Output

When you start a `qmgr` session, and standard output is connected to a terminal, `qmgr` writes a command prompt to standard output.

If you specify the `-e` option, `qmgr` echoes the directives it reads from standard input to standard output.

3.11.12 Standard Error

If you do not specify the `-z` option, the `qmgr` command writes a diagnostic message to standard error for each error occurrence.

3.11.13 Exit Status

0
: Success

1
: Error in parsing

2
: Error in execution

3
: Error connecting to server

4
: Error making object active

5
: Memory allocation error

3.11.14 See Also

The PBS Professional Administrator's Guide, “Attributes” on page 277 of the PBS Professional Reference Guide, “List of Built-in Resources” on page 259 of the PBS Professional Reference Guide

3.12 qselect

Selects specified PBS jobs

3.12.1 Synopsis

qselect [-a [<op>] <date and time>] [-A <account string>] [-c [<op>] <interval>] [-h <hold list>] [-H] [-J] [-l <resource list>] [-N <name>] [-p [<op>] <priority>] [-P <project>] [-q <destination>] [-r <rerun>] [-s <states>] [-t <time option> [<comparison>] <specified time>] [-T] [-u <user list>] [-x]

qselect --version

3.12.2 Description

The `qselect` command lists those jobs that meet the specified selection criteria. You can compare certain job attribute values to specified values using a comparison operator shown as *op* in the option description.

You can select jobs, job arrays, or subjobs. You can select jobs from one server per call to the command.

Each option acts as a filter restricting which jobs are listed.

You can select jobs according to the values of some of the resources in the Resource_List job attribute. You can also select jobs according the selection directive (although because this is a string, you can only check for equality or inequality.)

Jobs that are finished or moved are listed only when the `-x` or `-H` options are used. Otherwise, job selection is limited to queued and running jobs.

3.12.2.1 Comparison Operations

You can select jobs by comparing the values of certain job attributes to values you specify. The following table lists the comparison operations you can use:

Table 3-14: Comparison Operations

Operation	Type of Comparison
.eq.	The value of the job attribute is equal to the value of the option argument.
.ne.	The value of the job attribute is not equal to the value of the option argument.
.ge.	The value of the job attribute is greater than or equal to the value of the option argument.
.gt.	The value of the job attribute is greater than the value of the option argument.
.le.	The value of the job attribute is less than or equal to the value of the option argument.
.lt.	The value of the job attribute is less than the value of the option argument.

For example, to select jobs whose Priority attribute has a value greater than 5:

```
qselect -p.gt.5
```

Where an optional comparison is not specified, the comparison operation defaults to *.eq*, meaning PBS checks whether the value of the attribute is equal to the option argument.

3.12.2.2 Required Permissions

When selecting jobs according to resource values, users without operator or manager privilege cannot specify custom resources which were created to be invisible to unprivileged users.

3.12.3 Options to `qselect`

(no options)

Lists all jobs at the server which the user is authorized to list (query status of).

-a [<op>] <date and time>

Deprecated. Restricts selection to those jobs whose Execution_Time attribute qualifies when compared to the *date and time* argument. You can select a range of execution times by using this option twice, to compare to a minimum time and a maximum time.

The *date and time* argument has the format:

[[CC]YY]MMDDhhmm[.SS]

where *MM* is the two digits for the month, *DD* is the day of the month, *hh* is the hour, *mm* is the minute, and the optional *SS* is the seconds. *CC* is the century and *YY* the year.

-A <account string>

Restricts selection to jobs whose Account_Name attribute matches the specified *account string* .

-c [<op>] <interval>

Restricts selection to jobs whose Checkpoint interval attribute meets the comparison criteria.

The *interval* argument can take one of the following values:

c

c=<minutes>

n

s

w

w=<minutes>

We give the range of interval values for the Checkpoint attribute the following ordered relationship:

n > s > c=<minutes> > c > u

(Information about w and w=<minutes> is not available.)

For an interval value of "*u*", only "*.eq.*" and "*.ne.*" are valid.

-h <hold list>

Restricts the selection of jobs to those with a specific set of hold types. The holds in the Hold_Types job attribute must be the same as those in the *hold list* argument, but can be in a different order.

The *hold list* argument is a string consisting of the single letter *n*, or one or more of the letters *u, o, p*, or *s* in any combination. If letters are duplicated, they are treated as if they occurred once. The letters represent the hold types:

Table 3-15: Hold Types

Letter	Hold Type
n	None
u	User
o	Other
p	Bad password
s	System

-H

Restricts selection to finished and moved jobs.

-J

Limits selection to job arrays only.

-l <resource list>

Restricts selection of jobs to those with specified resource amounts. Resource must be job-wide, or be mem, ncpus, or vmem.

The *resource list* is in the following format:

<resource name> <op> <value>[,<resource name> <op> <value> ...]

You must specify *op*, and you can use any of the comparison operators.

Because resource specifications for chunks using the select statement, and placement using the place statement, are stored as strings, the only useful operators for these are *.eq.* and *.ne.*

Unprivileged users cannot specify custom resources which were created to be invisible to unprivileged users.

-N <name>

Restricts selection of jobs to those with the specified value for the Job_Name attribute.

-p [<op>]<priority>

Restricts selection of jobs to those with the specified Priority value(s).

-P <project>

Restricts selection of jobs to those matching the specified value for the project attribute.

Format: *Project Name*; see "Project Name" on page 357

-q <destination>

Restricts selection to those jobs at the specified *destination*.

The *destination* may take of one of the following forms:

<queue name>

Restricts selection to the specified queue at the default server.

@<server name>

Restricts selection to the specified server.

<queue name>@<server name>

Restricts selection to the specified queue at the specified server.

If the -q option is not specified, jobs are selected from the default server.

-r <rerun>

Restricts selection of jobs to those with the specified value for the Rerunable attribute . The option argument *rerun* must be a single character, either *y* or *n* .

-s <states>

Restricts job selection to those whose job_state attribute has the specified value(s).

The *states* argument is a character string consisting of any combination of these characters: *B, E, F, H, M, Q, R, S, T, U, W*, and *X*. (A repeated character is accepted, but no additional meaning is assigned to it.)

Table 3-16: Job States

State	Meaning
B	Job array has started execution
E	The *Exiting* state
F	The *Finished* state
H	The *Held* state
M	The *Moved* state
Q	The *Queued* state
R	The *Running* state
S	The *Suspended* state
T	The *Transiting* state
U	Job suspended due to workstation user activity
W	The *Waiting* state
X	The *eXited* state. Subjobs only

Jobs in any of the specified states are selected.

Job arrays are never in states *R, S, T*, or *U*. Subjobs may be in those states.

-t <time option> [<op>] <specified time>

Jobs are selected according to one of their time-based attributes. The *time option* specifies which time-based attribute is tested. You give the *specified time* in *datetime* format. See Chapter 7, "Formats", on page 353.

The *time option* is one of the following:

Table 3-17: Sub-options to the `-t` Option

Time Option	Time Attribute	Option Format(s)	Attribute Description
a	Execution_Time	*Timestamp* Use *datetime* format to specify.	Time at which the job is eligible for execution.
c	ctime	*Timestamp* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.	Time at which the job was created.
e	etime	*Timestamp* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.	Time when job became eligible to run, i.e. was enqueued in an execution queue and was in the "*Q*" state. Reset when a job moves queues, or is held then released. Not affected by qaltering.
g	eligible_time	Use *duration* format to specify.	Amount of eligible time job accrued waiting to run.
m	mtime	*Timestamp* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.	Time that the job was last modified, changed state, or changed locations.
q	qtime	*Timestamp* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.	Time that the job entered the current queue.
s	stime	*Timestamp* Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch	Time the job started. Updated when job is restarted. .
t	estimated.start_time	Use *datetime* format to specify. Printed by `qstat` in human-readable *Date* format. Output in hooks as seconds since epoch.	Job's estimated start time.

To bracket a time period, use the `-t` option twice. For example, to select jobs using stime between noon and 3 p.m.:

```
qselect -ts.gt.09251200 -ts.lt.09251500
```

-T

Limits selection to jobs and subjobs.

-u <user list>

Restricts selection to jobs owned by the specified usernames.

Syntax of *user list*:

<username>[@<hostname>][,<username>[@<hostname>],...]

Selects jobs which are owned by the listed users at the corresponding hosts. Hostnames may be wildcarded on the left end, e.g. "*.nasa.gov". A username without a "@<hostname>" is equivalent to "<username>@*", meaning that it is valid at any host.

-x

Selects finished and moved jobs in addition to queued and running jobs.

--version

The `qselect` command returns its PBS version information and exits. This option can only be used alone.

3.12.4 Standard Output

PBS writes a list of the selected job IDs to standard output. Each job ID is separated by white space. A job ID can represent a job, a job array, or a subjob. Each job ID has one of the forms:

<sequence number>.<server name>[@<server name>]

<sequence number>[].<server name>[@<server name>]

<sequence number>[<index>].<server name>[@<server name>]

@<server name> identifies the server which currently owns the job.

3.12.5 Standard Error

The `qselect` command writes a diagnostic message to standard error for each error occurrence.

3.12.6 Exit Status

Zero

Upon successful processing of all options presented to the `qselect` command

Greater than zero

If the `qselect` command fails to process any option

3.12.7 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide, section 6.11, “Job Attributes”, on page 327, Chapter 5, "List of Built-in Resources", on page 259

3.12.8 Caveats

You cannot use `qselect` with rerunnable jobs; you cannot specify `qselect -r y`.

3.13 qstat

Displays status of PBS jobs, queues, or servers

3.13.1 Synopsis

3.13.1.1 Displaying Job Status

Default format:

qstat [-E] [-J] [-p] [-t] [-w] [-x] [[<job ID> | <destination>] ...]

Long format:

qstat -f [-F json|dsv [-D <delimiter>]] [-E] [-J] [-p] [-t] [-w] [-x] [[<job ID> | <destination>] ...]

Alternate format:

qstat [-a | -H | -i | -r] [-E] [-G | -M] [-J] [-n [-1]] [-s [-1]] [-t] [-T] [-u <user list>] [-w] [[<job ID> | <destination>] ...]

3.13.1.2 Displaying Queue Status

Default format:

qstat -Q [<destination> ...]

Long format:

qstat -Q -f [-F json|dsv [-D <delimiter>]] [-w] [<destination> ...]

Alternate format:

qstat -q [-G | -M] [<destination> ...]

3.13.1.3 Displaying Server Status

Default format:

qstat -B [<server name> ...]

Long format:

qstat -B -f [-F json|dsv [-D <delimiter>]] [-w] [<server name> ...]

3.13.1.4 Displaying Version Information

qstat --version

3.13.2 Description

The `qstat` command displays the status of jobs, queues, or servers, writing the status information to standard output.

When displaying job status information, the `qstat` command displays status information about all specified jobs, job arrays, and subjobs. You can specify jobs by ID, or by destination, for example all jobs at a specified queue or server.

3.13.2.1 Display Formats

You can use particular options to display status information in a default format, an alternate format, or a long format. Default and alternate formats display all status information for a job, queue, or server with one line per object, in columns. Long formats display status information showing all attributes, one attribute to a line.

3.13.2.2 Displaying Truncated Data

When the number of characters required would exceed the space available, `qstat` truncates the output and puts an asterisk ("*") in the last position. For example, in default job display format, there are three characters allowed for the number of cores. If the actual output were *1234*, the value displayed would be *12** instead.

3.13.2.3 Required Privilege

Users without Manager or Operator privilege cannot view resources or attributes that are invisible to unprivileged users.

3.13.3 Displaying Job Status

3.13.3.1 Job Status in Default Format

Triggers: no options, or any of the `-J`, `-p`, `-t`, or `-x` options.

The `qstat` command displays job status in default format when you specify no options, or any of the `-J`, `-p`, `-t`, or `-x` options. Jobs are displayed one to a line, with these column headers:

```
Job id   Name       User      Time Use S Queue
-------- ---------- --------- -------- - -----
```

Description of columns:

Table 3-18: Description of Default Job Status Columns

Column	Width without -w	Width with -w	Description
Job ID	17 (22 when max_job_sequence_id > 10 million	30	Job ID assigned by PBS
Name	16	15	Job name specified by submitter
User	16	15	Username of job owner

Table 3-18: Description of Default Job Status Columns

Column	Width without -w	Width with -w	Description	
Time Use or Percent Complete	8	8	The CPU time used by the job. Before the application has actually started running, for example during stage-in, this field is "0". At the point where the application starts accumulating cput, this field changes to "00:00:00". After that, every time the MoM polls for resource usage, the field is updated. The MoM on each execution host polls for the usage of all processes on her host belonging to the job. Usage is summed. The polling interval is short when a job first starts running and lengthens to a maximum of 2 minutes. See "Configuring MoM Polling Cycle" on page 38 in the PBS Professional Administrator's Guide. If you specify -p, the *Time Use* column is replaced with the percentage completed for the job. For a job array this is the percentage of subjobs completed. For a normal job, it is the percentage of allocated CPU time used.	
S	1	1	The job's state. See section 8.1, "Job States", on page 361	
			B	Array job has at least one subjob running
			E	Job is exiting after having run
			F	Job is finished
			H	Job is held
			M	Job was moved to another server
			Q	Job is queued
			R	Job is running
			S	Job is suspended
			T	Job is being moved to new location
			U	Cycle-harvesting job is suspended due to keyboard activity
			W	Job is waiting for its submitter-assigned start time to be reached
			X	Subjob has completed execution or has been deleted
Queue	16	15	The queue in which the job resides	

3.13.3.2 Job Status in Long Format

Trigger: the -f option.

If you specify the -f (full) option, full job status information for each job is displayed in this order:

- The job ID
- Each job attribute, one to a line
- The job's submission arguments
- The job's executable, in JSDL format
- The executable's argument list, in JSDL format

The job attributes are listed as <*name*> = <*value*> pairs. This includes the exec_host and exec_vnode strings. The full output can be very large.

The exec_host string has this format:

<host1>/<T1><P1>[+<host2>/<T2>*<P2>+...]*

where

T1 is the task slot number (the index) of the job on host1.

P1 is the number of processors allocated to the job from host1. The number of processors allocated does not appear if it is 1.

The exec_vnode string has the format:

(<vnode1>:ncpus=<N1>:mem=<M1>)[+(<vnode2>:ncpus=<N2>:mem=<M2>)+...]

where

N1 is the number of CPUs allocated to that job on *vnode1*.

M1 is the amount of memory allocated to that job on *vnode1*.

3.13.3.3 Job Status in Alternate Format

Triggers: any of the -a, -i, -G, -H, -M, -n, -r, -s, -T, or -u <user list> options.

The qstat command displays job status in alternate format if you specify any of the -a, -i, -G, -H, -M, -n, -r, -s, -T, or -u <user list> options. Jobs are displayed one to a line. If jobs are running and the -n option is specified, or if jobs are finished or moved and the -H and -n options are specified, there is a second line for the exec_host string.

3.13.3.3.i Job Status Alternate Format Output Columns

Alternate format job status output contains the following columns:

```
                                                  Req'd  Req'd   Elap
Job ID Username Queue Jobname SessID NDS TSK Memory Time  S Time
------ -------- ----- ------- ------ --- --- ------ ----- - ----
```

Description of columns:

Table 3-19: Description of Alternate Format Job Status Columns

Column	Width without -w	Width with -w	Description
Job ID	15 (20 when max_job_sequence_id > 10 million)	30	The job ID assigned by PBS
Username	8	15	Username of job owner
Queue	8	15	Queue in which the job resides
Jobname	10	15	Job name specified by submitter
SessID	6	8	Session ID. Appears only if the job is running
NDS	3	4	Number of chunks or vnodes requested by the job
TSK	3	5	Number of CPUs requested by the job
Req'd Memory	6	6	Amount of memory requested by the job
Req'd Time	5	5	If CPU time is requested, shows CPU time. Otherwise, shows walltime
S	1	1	The job's state; see "States" on page 361 for states
Elap Time or Est Start Time	5	5	If CPU time is requested, shows CPU time. Otherwise, shows walltime. If you use the `-P` option, displays estimated start time for queued jobs, replacing the *Elap Time* field with the *Est Start Time* field.

3.13.3.4 Grouping Jobs and Sorting by ID

Trigger: the `-E` option.

You can use the `-E` option to sort and group jobs in the output of `qstat`. The `-E` option groups jobs by server and displays each group by ascending ID. This option also improves `qstat` performance. The following table shows how the `-E` option affects the behavior of `qstat`:

Table 3-20: How -E Option Affects qstat Output

How qstat is Used	Result Without -E	Result With -E
`qstat` (no job ID specified)	Queries the default server and displays result	No change in behavior; same as without `-E` option
`qstat <list of job IDs from single server>`	Displays results in the order specified	Displays results in ascending ID order
`qstat <job IDs at multiple servers>`	Displays results in the order they are specified	Groups jobs by server. Displays each group in ascending order

3.13.4 Displaying Queue Status

3.13.4.1 Queue Status in Default Format

Trigger: the -Q option by itself.

The qstat command displays queue status in default format if the only option is -Q. Queue status is displayed one queue to a line, with these column headers:

```
Queue       Max  Tot  Ena  Str Que  Run  Hld  Wat  Trn  Ext  Type
----------- ---- ---- ---- --- ---- ---- ---- ---- ---- ---- ----
```

Description of columns:

Table 3-21: Description of Default Queue Status Columns

Column	Description
Queue	Queue name
Max	Maximum number of jobs allowed to run concurrently in this queue
Tot	Total number of jobs in the queue
Ena	Whether the queue is enabled or disabled
Str	Whether the queue is started or stopped
Que	Number of queued jobs
Run	Number of running jobs
Hld	Number of held jobs
Wat	Number of waiting jobs
Trn	Number of jobs being moved (transiting)
Ext	Number of exiting jobs
Type	Type of queue: execution or routing

3.13.4.2 Queue Status in Long Format

Trigger: the -q and -f options together.

If you specify the -f (full) option with the -q option, full queue status information for each queue is displayed starting with the queue name, followed by each attribute, one to a line, as <*name*> = <*value*> pairs.

3.13.4.2.i Queue Status: Alternate Format

Triggers: any of the -q, -G, or -M options.

The qstat command displays queue status in the alternate format if you specify any of the -q, -G, or -M options. Queue status is displayed one queue to a line, and the lowest line contains totals for some columns.

These are the alternate format queue status column headers:

```
Queue   Memory CPU Time Walltime Node Run Que Lm State
------- ------ -------- -------- ---- --- --- -- -----
```

Description of columns:

Table 3-22: Description of Queue Alternate Status Columns

Column	Description
Queue	Queue name
Memory	Maximum amount of memory that can be requested by a job in this queue
CPU Time	Maximum amount of CPU time that can be requested by a job in this queue
Walltime	Maximum amount of walltime that can be requested by a job in this queue
Node	Maximum number of vnodes that can be requested by a job in this queue
Run	Number of running and suspended jobs. Lowest row is total number of running and suspended jobs in all the queues shown
Que	Number of queued, waiting, and held jobs. Lowest row is total number of queued, waiting, and held jobs in all the queues shown
Lm	Maximum number of jobs allowed to run concurrently in this queue
State	State of this queue: *E* (enabled) or *D* (disabled), and *R* (running) or *S* (stopped)

3.13.5 Displaying Server Status

3.13.5.1 Server Status in Default Format:

Trigger: the `-B` option.

The `qstat` command displays server status if the only option given is `-B`.

Column headers for default server status output:

```
Server   Max   Tot   Que   Run   Hld   Wat   Trn   Ext   Status
-------- ----- ----- ----- ----- ----- ----- ----- ----- ------
```

Description of columns:

Table 3-23: Description of Server Status Default Display Columns

Column	Description
Server	Name of server
Max	Maximum number of jobs allowed to be running concurrently on the server
Tot	Total number of jobs currently managed by the server
Que	Number of queued jobs
Run	Number of running jobs
Hld	Number of held jobs
Wat	Number of waiting jobs

Table 3-23: Description of Server Status Default Display Columns

Column	Description
Trn	Number of transiting jobs
Ext	Number of exiting jobs
Status	Status of the server

3.13.5.2 Server Status in Long Format

Trigger: the `-f` option.

If you specify the `-f` (full) option, displays full server status information starting with the server name, followed by each server attribute, one to a line, as <*name*> = <*value*> pairs. Includes PBS version information.

3.13.6 Options to `qstat`

3.13.6.1 Generic Job Status Options

-E

Groups jobs by server and displays jobs sorted by ascending ID. When `qstat` is presented with a list of jobs, jobs are grouped by server and each group is displayed by ascending ID. This option also improves `qstat` performance. See section 3.13.3.4, "Grouping Jobs and Sorting by ID", on page 82.

3.13.6.2 Default Job Status Options

The following options cause job status information to be displayed in default format:

-J

Displays status information for job arrays (not subjobs).

-t

Displays status information for jobs, job arrays, and subjobs. When used with `-J` option, displays status information for subjobs only.

-p

The *Time Use* column is replaced with the percentage completed for the job. For a job array this is the percentage of subjobs completed. For a normal job, it is the percentage of allocated CPU time used.

-x

Displays status information for finished and moved jobs in addition to queued and running jobs.

3.13.6.3 Alternate Job Status Options

The following options cause job status information to be displayed in alternate format:

-a

All queued and running jobs are displayed. If a *destination* is specified, information for all jobs at that *destination* is displayed. If a *job ID* is specified, information about that job is displayed. Always specify this option before the `-n` or `-s` options, otherwise they will not take effect.

-H

Without a job identifier, displays information for all finished or moved jobs. If a *job ID* is given, displays information for that job regardless of its state. If a *destination* is specified, displays information for finished or moved jobs, or specified job(s), at *destination*.

-i

If a *destination* is given, information for queued, held or waiting jobs at that *destination* is displayed. If a *job ID* is given, information about that job is displayed regardless of its state.

-n

The exec_host string is listed on the line below the basic information. If the `-1` option is given, the exec_host string is listed on the end of the same line. If using the `-a` option, always specify the `-n` option after -a, otherwise the `-n` option does not take effect.

-r

If a *destination* is given, information for running or suspended jobs at that *destination* is displayed. If a *job ID* is given, information about that job is displayed regardless of its state.

-s

Any comment added by the administrator or scheduler is shown on the line below the basic information. If the `-1` option is given, the comment string is listed on the end of the same line. If using the `-a` option, always specify the `-s` option after `-a`, otherwise the `-s` option does not take effect.

-u <user list>

If a *destination* is given, status for jobs at that *destination* owned by users in *user list* is displayed. If a *job ID* is given, status information for that job is displayed regardless of the job's ownership.

Format: *<username>[@<hostname>][, <username>[@<hostname>], ...]* in comma-separated list.

Hostnames may be wildcarded, but not domain names. When no hostname is specified, *username* is for any host.

-w

Can be used with job status in default and alternate formats. Allows display of wider fields up to 120 characters. See section 3.13.3.1, “Job Status in Default Format”, on page 79 and section 3.13.3.3, “Job Status in Alternate Format”, on page 81 for column widths.

This option is different from the `-w` option used with the `-f` long-format option.

-1 (hyphen one)

Reformats `qstat` output to a single line. Can be used only in conjunction with the `-n` and/or `-s` options.

3.13.6.4 Queue Status Options

-Q

Displays queue status in default format. Operands must be *destinations*.

-q

Displays queue status in alternate format. Operands must be *destinations*.

3.13.6.5 Server Status Options

-B

Display server status. Operands must be names of servers.

3.13.6.6 Job, Queue, and Server Status Options

-f [-w]

Full display for long format. Job, subjob, queue, or server attributes displayed one to a line.

JSON output:

If MoM returns a JSON object (a Python dictionary), PBS reports the value as a string in single quotes:

```
resources_used.<resource_name> = '{ <MoM JSON item value>, <MoM JSON item value>, <MoM JSON item value>, ...}'
```

Example: MoM returns { "a":1, "b":2, "c":1,"d": 4} for resources_used.foo_str. We get:

```
resources_used.foo_str='{"a": 1, "b": 2, "c":1,"d": 4}'
```

If MoM returns a value that is not a valid JSON object, the value is reported verbatim.

Example: MoM returns "hello" for resources_used.foo_str. We get:

```
resources_used.foo_str="hello"
```

Optional -w prints each attribute on one unbroken line. Feed characters are converted:

- Newline is converted to backslash concatenated with "n", resulting in "\n"
- Form feed is converted to backslash concatenated with "f", resulting in "\f"

This -w is independent of the -w job output option used with default and alternate formats.

-F dsv [-D <delimiter>]

Prints output in delimiter-separated value format. The default *delimiter* is a pipe ("|"). You can specify a character or a string *delimiter* using the -D argument to the -F dsv option. For example, to use a comma as the delimiter:

```
qstat -f -F dsv -D,
```

If the delimiter itself appears in a value, it is escaped:

- On Linux, the delimiter is escaped with a backslash ("\").
- On Windows, the delimiter is escaped with a caret ("^").

Feed characters are converted:

- Newline is converted to backslash concatenated with "n", resulting in "\n"
- Form feed is converted to backslash concatenated with "f", resulting in "\f"

A newline separates each job from the next. Using newline as the delimiter leads to undefined behavior.

Example of getting output in delimiter-separated value format:

```
qstat -f -Fdsv
Job Id: 1.vbox|Job_Name = STDIN|Job_Owner = root@vbox|job_state = Q|queue = workq|server = vbox|Checkpoint = u|ctime = Fri Nov 11 17:57:05 2016|Error_Path = ...
```

-F json

Prints output in JSON format (http://www.json.org/).

Attribute output is preceded by timestamp, PBS version, and PBS server hostname.

Example:

```
qstat -f -F json
{
    "timestamp":1479277336,
    "pbs_version":"14.1",
    "pbs_server":"vbox",
    "Jobs":{
        "1.vbox":{
            "Job_Name":"STDIN",
            "Job_Owner":"root@vbox",
            "job_state":"Q",
...
```

-G

Shows size in gigabytes. Triggers alternate format.

-M

Shows size in megawords. A word is considered to be 8 bytes. Triggers alternate format.

3.13.6.7 Version Information

--version

The `qstat` command returns its PBS version information and exits. This option can only be used alone.

3.13.7 Operands

3.13.7.1 Job Identifier Operands

The *job ID* is assigned by PBS at submission. Job IDs are used only with job status requests. Status information for specified job(s) is displayed. Formats:

Job ID:

<sequence number>[.<server name>][@<server name>]

Job array ID:

<sequence number>[][.<server name>][@<server name>]

Subjob ID:

<sequence number>[<index>][.<server name>][@<server name>]

Range of subjobs:

<sequence number>[<index start>-<index end>][.<server name>][@<server name>]

Note that some shells require that you enclose a job array identifier in double quotes.

3.13.7.2 Destination Operands

Name of queue, name of server, or name of queue at a specific server. Formats:

queue name

Specifies name of queue for job or queue display.

- When displaying job status, PBS displays status for all jobs in the specified queue at the default server.
- When displaying queue status, PBS displays status for the specified queue at the default server.

queue name@server name

Specifies name of queue at server for job or queue display.

- When displaying job status, PBS displays status for all jobs in the specified queue at the specified server.
- When displaying queue status, PBS displays status for the specified queue at the specified server.

@server name

Specifies server name for job or queue display.

- When displaying job status, PBS displays status for all jobs at all queues at the specified server.
- When displaying queue status, PBS displays status for all queues at the specified server.

server name

Specifies server name for server display.

- When displaying server status (with the `-B` option) PBS displays status for the specified server.

3.13.8 Standard Error

The `qstat` command writes a diagnostic message to standard error for each error occurrence.

3.13.9 Exit Status

Zero

Upon successful processing of all operands

Greater than zero

If any operands could not be processed

3.13.10 See Also

The PBS Professional User's Guide, the PBS Professional Administrator's Guide, "Attributes” on page 277

3.13.11 Caveats

This version of `qstat` displays finished jobs first.

3.14 qsub

Submits a job to PBS

3.14.1 Synopsis

simsh <path to snapshot> qsub [-a <date and time>] [-A <account string>] [-c <checkpoint spec>] [-C <directive prefix>] [-e <path>] [-f] [-h] [-j <join>] [-J <range> [%<max subjobs]] [-k <discard>] [-l <resource list>] [-N <name>] [-o <path>] [-p <priority>] [-P <project>] [-q <destination>] [-r <y | n>] [-R <remove options>] [-S <path list>] [-u <user list>] [-W <additional attributes>] [-z] [- | <script> | -- <executable> [<arguments to executable>]]

simsh <path to snapshot> qsub --version

3.14.2 Description

You use the `qsub` command to submit a batch job to a snapshot. Submitting a PBS job requests resources and sets job attributes.

The `qsub` command can read from a job script, from standard input, or from the command line.

- To use a job script:

  simsh <path to snapshot> qsub [<options>] <job script containing directives and executable>

  simsh <path to snapshot> qsub [<options>] <directives> <job script containing other directives and executable>
- To submit from the command line:

  simsh <path to snapshot> qsub [<options>] <directives> -- <executable> <arguments to executable>
- To submit from standard input:

  simsh <path to snapshot> qsub <return>
  <directives>
  <executable>
  <CTRL-D>

When you have submitted the job, Simulate returns the job identifier for that job. For a job, this is of the form:

<sequence number>.<server name>

For an array job, this is of the form:

<sequence number>[].<server name>

3.14.2.1 Differences Between Simulation and Live Execution

- In a simulation, directives are processed but the job executable does not run. You can use a normal job script; just be awarethat everything but the directives is ignored.
- Simulate ignores job environment variables: it does not use the value of the job's Variable_List attribute.
- In a simulation, each job runs until the end of its requested walltime, instead of the amount of time the job would actually have run. For example, if a job requests one hour of walltime, but the job would finish in 5 minutes in the real world, the simulated job runs for one hour.

3.14.2.2 Submitting Jobs By Using Job Scripts

If you use a job script to specify job directives, Simulate reads the directives from the script. The script can contain an executable, but does not require an executable. If you use the command line to specify directives, the job script must exist but can be empty.

Job scripts can be written in Python, Linux shells such as `csh` and `sh`, the Windows command batch language, Perl, etc.

A PBS job script consists of the following:

- Optional shell specification
- Any PBS directives
- Optional comments

  Under Windows, comments can contain only ASCII characters. See the PBS Professional User's Guide.

3.14.2.2.i Using Shells and Interpreters

You can optionally specify a different shell or interpreter to run your script (but the shell or interpreter does not run in the simulation):

- Via the `-S` option to `qsub`:

  simsh <path to snapshot> qsub -S <path to shell> <script name>

  For example:

  simsh <path to snapshot> qsub -S /bin/bash myscript.sh
- In the first line of your script. For example:

  cat myscript.sh

```
#!/bin/sh
#PBS -N MyHelloJob
print "Hello"
```

3.14.2.2.ii Python Job Scripts

You can use the same Python script under Linux or under Windows, if the script is written to be portable. The simulator does not run the Python commands. PBS includes a Python package, allowing Python job scripts to run; you do not need to install Python. You can include PBS directives in a Python job script as you would in a Linux shell script. Python job scripts can access Win32 APIs, including the following modules:

Win32api

Win32con

Pywintypes

Example 3-15: We have a Python job script that includes PBS directives:

cat myjob.py

```
#!/usr/bin/python
#PBS -l select=1:ncpus=3:mem=1gb
#PBS -N HelloJob
print "Hello"
```

To run a Python job script under Linux, use the Python path on the execution host:

simsh <path to snapshot> qsub -S <Python path on execution host> <script name>

For example,

simsh <path to snapshot> qsub -S $PBS_EXEC/bin/pbs_python <script name>

To run a Python job script under Windows, use the Python path on the execution host:

simsh <path to snapshot> qsub -S <Python path on execution host> <script name>

For example:

```
simsh <path to snapshot> qsub -S %PBS_EXEC%\bin\pbs_python.exe <script name>
```

If the script pathname contains spaces, it must be quoted, for example:

```
simsh <path to snapshot> qsub -S "C:\Program Files\PBS\bin\pbs_python.exe" <script name>
```

3.14.2.2.iii Linux Shell Job Scripts

Example 3-16: We have a Linux job script named "weatherscript" for a job named "Weather1" on Linux:

```
#!/bin/sh
#PBS -N Weather1
#PBS -l walltime=1:00:00
```

To submit the job, the user types:

```
simsh <path to snapshot> qsub weatherscript <return>
```

3.14.2.2.iv Windows Command Job Scripts

Example 3-17: We have a script named "weather.exe" for a job named "Weather1" which runs under Windows:

```
#PBS -N Weather1
#PBS -l walltime=1:00:00
```

To submit the job, the user types:

```
simsh <path to snapshot> qsub weather.exe <return>
```

In Windows, if you use `notepad` to create a job script, the last line does not automatically get newline-terminated. Be sure to put one explicitly, otherwise, PBS job will get the following error message:

```
More?
```

when the Windows command interpreter tries to execute that last line.

3.14.2.3 Submitting Jobs From Standard Input

When you submit a job from standard input, you do not need to specify an executable. To submit a PBS job by typing job specifications at the command line, you type:

simsh <path to snapshot> qsub [<options>] [-] <return>

then type any directives, followed by:

- Linux: `CTRL-D` on a line by itself
- Windows: `CTRL-Z <return>`

to terminate the input.

The `qsub` command behaves the same both with and without the dash operand.

For example, on Linux:

```
simsh <path to snapshot> qsub <return>
#PBS -N StdInJob
#PBS -l walltime=1:00:00
<CTRL-D>
```

3.14.2.4 Submitting Job Directly by Specifying Executable on Command Line

To submit a job directly, you specify the executable on the command line:

simsh <path to snapshot> qsub [<options>] -- <executable> [<arguments to executable>] <return>

When you run `qsub` this way, it does not start a shell, so no shell initialization scripts are run, and execution paths and other environment variables are not set. There is not an easy way to specify your command in a different directory. You will usually have to specify the full path to the command.

Example 3-18: To specify `myprog` with the arguments *a* and *b*, naming the job "JobA":

```
simsh <path to snapshot> qsub -N JobA -- myprog a b <return>
```

Example 3-19: To submit a job to the snapshot named "formula_one":

```
simsh formula_one qsub -N sim_job -l select=1:ncpus=32:mem=16gb -l walltime=0:10:00 -- /bin/sleep
    60
```

3.14.2.5 Requesting Resources and Placing Jobs

Requesting resources includes setting limits on resource usage and controlling how the job is placed on vnodes.

Resources are requested by using the `-l` option, either in job-wide requests using *<resource name>=<value>* pairs, or in chunks inside of *selection statements*. See Chapter 5, "List of Built-in Resources", on page 259.

Job-wide *<resource name>=<value>* requests are of the form:

-l <resource name>=<value>[,<resource name>=<value> ...]

The selection statement is of the form:

-l select=[<N>:]<chunk>[+[<N>:]<chunk> ...]

where *N* specifies how many of that chunk, and a *chunk* is of the form:

<resource name>=<value>[:<resource name>=<value> ...]

You choose how your chunks are placed using the *place statement*. The *place statement* can contain the following elements, in any order:

-l place=[<arrangement>][: <sharing>][: <grouping>]

where

arrangement

Whether this chunk is willing to share this vnode or host with other chunks from the same job. One of *free* | *pack* | *scatter* | *vscatter*

sharing

Whether this this chunk is willing to share this vnode or host with other jobs. One of *excl* | *shared* | *exclhost*

grouping

Whether the chunks from this job should be placed on vnodes that all have the same value for a resource. Can have only one instance of *group=<resource name>*

free

Place job on any vnode(s).

pack

All chunks are taken from one host.

scatter

Only one chunk with any MPI processes is taken from a host. A chunk with no MPI processes may be taken from the same vnode as another chunk.

vscatter

Only one chunk is taken from any vnode. Each chunk must fit on a vnode.

excl

Only this job uses the vnodes chosen.

shared

This job can share the vnodes chosen.

exclhost

The entire host is allocated to the job.

group=<resource name>

Chunks are grouped according to a resource. All vnodes in the group must have a common value for *resource*, which can be either the built-in resource host or a custom vnode-level resource.

resource name must be a string or a string array.

The place statement cannot begin with a colon. Colons are delimiters; use them only to separate parts of a place statement, unless they are quoted inside resource values.

Note that vnodes can have sharing attributes that override job placement requests. See section 6.10, “Vnode Attributes”, on page 320.

For more on resources, resource requests, usage limits, and job placement, see "Using PBS Resources" on page 227 in the PBS Professional Administrator’s Guide and "Allocating Resources & Placing Jobs", on page 51 of the PBS Professional User’s Guide.

3.14.2.5.i Caveats for Requesting Resources

Do not mix old-style resource or vnode specifications with the new *select* and *place* statements. Do not use one in a job script and the other on the command line. Mixing the two will result in an error.

You cannot submit a job requesting a custom resource which has been created to be invisible or read-only for unprivileged users, regardless of your privilege. A Manager or Operator can use the `qalter` command to change a job's request for this kind of custom resource.

3.14.2.6 Setting Attributes

The job submitter sets job attributes by giving options to the `qsub` command or by using PBS directives. Most `qsub` options set a job attribute, and have a corresponding PBS directive with the same syntax as the option. Attributes set via command-line options take precedence over those set using PBS directives. See the PBS Professional User's Guide, `or` section 6.11, “Job Attributes”, on page 327.

3.14.2.7 Running Your Job on First Available Resources

You may want to run a job on whichever resources become available first, even if the job could run on other sets of resources. You may want to start a flexible job as soon as possible on a smaller set of resources rather than waiting longer for a larger set of resources, or you may prefer certain resources but be able to use others (for example, you might prefer a specific processor, but still be able to run on another if that is all that's available).

If you submit a set of jobs where each job has a "runone" dependency on the others, PBS runs only one of the jobs in the "runone set". PBS automatically groups the jobs into a runone set. The jobs in a runone set can run different scripts.

When any of the jobs in the set starts, PBS applies a system hold to the others. The hold on the other jobs is released when the running job is requeued:

- Via `qrerun`
- When node fail requeue is triggered

The other jobs in the set are deleted:

- When a job ends, regardless of its exit status
- When the running job is deleted

To identify a job as a member of the set, give it a "runone" dependency on the previously-submitted member of the set. For example, we have three jobs, each of which runs on different resources. To submit these three jobs as a runone set:

```
simsh <path to snapshot> qsub -lselect=200:ncpus=16 -lwalltime=1:00:00 myscript.sh
10.myserver
simsh <path to snapshot> qsub -lselect=100:ncpus=16 -lwalltime=2:00:00 -Wdepend=runone:10
   myscript.sh
11.myserver
simsh <path to snapshot> qsub -lselect=50:ncpus=16 -lwalltime=4:00:00 -Wdepend=runone:10
   myscript.sh
12.myserver
```

3.14.2.8 Changing `qsub` Behavior

The behavior of the `qsub` command may be affected by the server's default_qsub_arguments attribute. This attribute can set the default for any job attribute. The default_qsub_arguments server attribute is settable by the administrator, and is overridden by command-line arguments and script directives. See section 6.6, “Server Attributes”, on page 281.

3.14.3 Options to `qsub`

-a <date and time>

Point in simulated time after which the job is eligible for execution. Given in pairs of digits. Sets job's Execution_Time attribute to *date and time*.

Format: *datetime,* expressed as *[[[[CC]YY]MM]DD]hhmm[.SS]*

where *CC* is the century, *YY* is the year, *MM* is the month, *DD* is the day of the month, *hh* is the hour, *mm* is the minute, and *SS* is the seconds.

Each portion of the date defaults to the current date, as long as the next-smaller portion is in the future. For example, if today is the 3rd of the month and the specified day *DD* is the 5th, the month *MM* is set to the current month.

If a specified portion has already passed, the next-larger portion is set to one after the current date. For example, if the day *DD* is not specified, but the hour hh is specified to be 10:00 a.m. and the current time is 11:00 a.m., the day *DD* is set to tomorrow.

-A <account string>

Accounting string associated with the job. Used for labeling accounting data. Sets job's Account_Name attribute to *account string*.

Format: *String*

-c <checkpoint spec>

Determines when the job will be checkpointed. Sets job's Checkpoint attribute to *checkpoint spec*. An $action script is required to checkpoint the job.

See "Using Checkpointing", on page 115 of the PBS Professional User's Guide.

The argument *checkpoint spec* can take one of the following values:

c
: Checkpoint at intervals, measured in CPU time, set on job's execution queue. If there is no interval set at the queue, the job is not checkpointed

c=<minutes of CPU time>
: Checkpoint at intervals of specified number of minutes of job CPU time. This value must be greater than zero. If the interval specified is less than that set on the job's execution queue, the queue's interval is used.

  Format: *Integer*

w
: Checkpoint at intervals, measured in walltime, set on job's execution queue. If there is no interval set at the queue, the job is not checkpointed.

w=<minutes of walltime>
: Checkpoint at intervals of the specified number of minutes of job walltime. This value must be greater than zero. If the interval specified is less than that set on the job's execution queue, the queue's interval is used.

  Format: *Integer*

n
: No checkpointing.

s
: Checkpoint only when the server is shut down.

u
: Unset. Defaults to behavior when *interval* argument is set to *s*.

Default: *u*

Format: *String*

-C <directive prefix>

Defines the prefix identifying a PBS directive. Default prefix is "*#PBS*".

If the *directive prefix* argument is a null string, `qsub` does not scan the script file for directives. Overrides the PBS_DPREFIX environment variable and the default. The string "PBS_DPREFIX" cannot be used as a PBS directive. Length limit: 4096 characters.

-e <path>

Path to be used for the job's standard error stream. Sets job's Error_Path attribute to *path*. The *path* argument is of the form:

[<hostname>:]<path>

The *path* is interpreted as follows:

path
: If *path* is relative, it is taken to be relative to the current working directory of the `qsub` command, where it is executing on the current host.

  If *path* is absolute, it is taken to be an absolute path on the current host where the `qsub` command is executing.

hostname:path
: If *path* is relative, it is taken to be relative to the user's home directory on the host named *hostname*.

If *path* is absolute, it is an absolute path on the host named *hostname*.

If *path* does not include a filename, the default filename has the form *<job ID>.ER*

If the -e option is not specified, PBS copies the standard error to the current working directory where the qsub command was executed, and writes standard error to the default filename, which has this form:

<job name>.e<sequence number>

If you use a UNC path for output or error files, the *hostname* is optional. If you use a non-UNC path, the *hostname* is required.

This option is overridden by the -k option.

-f

Prevents qsub from spawning a background process. By default, qsub spawns a background process to manage communication with the PBS server. When this option is specified, the qsub process connects directly to the server and no background process is created.

NOTE: Use of this option degrades performance of qsub when calls to qsub are made in rapid succession.

-h

Applies a *User* hold to the job. Sets the job's Hold_Types attribute to "*u*".

-j <join>

Specifies whether and how to join the job's standard error and standard output streams. Sets job's Join_Path attribute to *join*.

Default: *n*; not merged

The *join* argument can take the following values:

Table 3-24: Sub-options to -j Option

Suboption	Meaning
oe	Standard error and standard output are merged into standard output.
eo	Standard error and standard output are merged into standard error.
n	Standard error and standard output are not merged.

-J <range> [%<max subjobs>]

Makes this job an array job. Sets job's array attribute to *True*.

Use the *range* argument to specify the indices of the subjobs of the array. *range* is specified in the form *X-Y[:Z]* where *X* is the first index, *Y* is the upper bound on the indices, and *Z* is the stepping factor. For example, 2-7:2 will produce indices of *2*, *4*, and *6*. If *Z* is not specified, it is taken to be *1*. Indices must be greater than or equal to zero.

Use the optional *%max subjobs* argument to set a limit on the number of subjobs that can be running at one time. This sets the value of the max_run_subjobs job attribute to the specified maximum.

Job arrays are always rerunnable.

-k <discard>

Specifies whether and which of the standard output and standard error streams is left behind on the execution host, or written to their final destination. Sets the job's Keep_Files attribute to *discard*.

k {e | o | eo | oe | n}

For the e, o, eo, oe, or n suboptions, overrides -o <output path> and -e <error path> options.

kd {e | o | eo | oe}

When used with the -d suboption, specifies that output and/or error files are written directly to the final destination. Requires e and/or o suboptions.

Default: *n*; neither is retained, and files are not written directly to final destinations.

In the case where output and/or error is retained on the execution host in a job-specific staging and execution directory created by PBS, these files are deleted when PBS deletes the directory.

The *discard* argument can take the following values:

Table 3-25: Sub-options to discard Option

Suboption	Meaning
e	The standard error stream is retained on the execution host, in the job's staging and execution directory. The filename is *<job name>.e<sequence number>*
o	The standard output stream is retained on the execution host, in the job's staging and execution directory. The filename is *<job name>.o<sequence number>*
eo, oe	Both standard output and standard error streams are retained on the execution host, in the job's staging and execution directory.
d<e and/or o>	Output and/or error are written directly to their final destination. Overrides action of leaving files on execution host. Requires e and/or o suboptions.
n	Neither stream is retained.

-l <resource list>

Allows the user to request resources and specify job placement. Sets job's Resource_list attribute to *resource list*. Requesting a resource places a limit on its usage.

For how to request resources and place jobs, see section 3.14.2.5, “Requesting Resources and Placing Jobs”, on page 93.

-N <name>

Sets job's Job_Name attribute and name to *name*.

Format: *Job Name*; see "Job Name, Job Array Name” on page 355

Default: if a script is used to submit the job, the job's name is the name of the script. If no script is used, the job's name is "*STDIN*".

-o <path>

Path to be used for the job's standard output stream. Sets job's Output_Path attribute to *path*. The *path* argument has the form:

[<hostname>:]<path>

The *path* is interpreted as follows:

path

If *path* is relative, it is taken to be relative to the current working directory of the command, where it is executing on the current host.

If *path* is absolute, it is taken to be an absolute path on the current host where the command is executing.

hostname:path

If *path* is relative, it is taken to be relative to the user's home directory on the host named *hostname*.

If *path* is absolute, it is an absolute path on the host named *hostname*.

If *path* does not include a filename, the default filename has the form *<job ID>.OU*

If the -o option is not specified, PBS copies the standard output to the current working directory where the qsub command was executed, and writes standard output to the default filename, which has this form:

<job name>.o<sequence number>

If you use a UNC path, the hostname is optional. If you use a non-UNC path, the hostname is required.

This option is overridden by the -k option.

-p <priority>

Priority of the job. Sets job's Priority attribute to *priority.*

Format: Host-dependent integer

Range: [-1024, +1023] inclusive

Default: *Zero*

-P <project>

Specifies a project for the job. Sets job's project attribute to *project*.

Format: *Project Name*; see "Project Name" on page 357

Default value: "*_pbs_project_default*".

-q <destination>

Where the job is sent upon submission.

Specifies a queue, a server, or a queue at a server. The destination argument can have one of these formats:

<queue name>

Job is submitted to the specified queue at the default server.

@<server name>

Job is submitted to the default queue at the specified server.

<queue name>@<server name>

Job is submitted to the specified queue at the specified server.

Default: Default queue at default server

-r <y|n>

Declares whether the job is rerunnable. Sets job's Rerunable attribute to the argument value. Does not affect how the job is handled in the case where the job was unable to begin execution.

Format: Single character, "*y*" or "*n*"

Table 3-26: Sub-options to r Option

Suboption	Meaning
y	Job is rerunnable.
n	Job is not rerunnable.

Default: "*y*"

Job arrays are always rerunnable. See "qrerun" on page 181.

-R <remove options>

Specifies whether standard output and/or standard error files are automatically removed (deleted) upon job completion.

Sets the job's Remove_Files attribute to *remove options*. Overrides default path names for these streams. Overrides -o and -e options.

This attribute cannot be altered once the job has begun execution.

Default: *Unset*; neither is removed

The *remove options* argument can take the following values:

Table 3-27: discard Argument Values

Option	Meaning
e	The standard error stream is removed (deleted) upon job completion
o	The standard output stream is removed (deleted) upon job completion
eo, oe	Both standard output and standard error streams are removed (deleted) upon job completion
unset	Neither stream is removed.

-S <path list>

Specifies the interpreter or shell path for the job script. Sets job's Shell_Path_List attribute to *path list*.

The *path list* argument is the full path to the interpreter or shell including the executable name.

Only one path may be specified without a hostname. Only one path may be specified per named host. The path selected is the one whose hostname is that of the server on which the job resides.

Format: *<path>[@<hostname>][,<path>@<hostname> ...]*

Default: User's login shell on execution host

Example of using `bash` via a directive:

```
#PBS -S /bin/bash@mars,/usr/bin/bash@jupiter
```

Example of running a Python script from the command line on Linux:

```
simsh <path to snapshot> qsub -S $PBS_EXEC/bin/pbs_python <script name>
```

Example of running a Python script from the command line on Windows:

```
simsh <path to snapshot> qsub -S %PBS_EXEC%\bin\pbs_python.exe <script name>
```

-u <user list>

List of usernames. Job is run under a username from this list. Sets job's User_List attribute to *user list*.

Only one username may be specified without a hostname. Only one username may be specified per named host. The server on which the job resides will select first the username whose hostname is the same as the server name. Failing that, the next selection is the username with no specified hostname. The usernames on the server and execution hosts must be the same. The job owner must have authorization to run as the specified user.

Format of *user list: <username>[@<hostname>][,<username>@<hostname> ...]*

Default: Job owner (username on submission host)

-W <additional attributes>

The `-W` option allows specification of some job attributes. Some job attributes must be specified using this option. Those attributes are listed below. Format:

-W <attribute name>=<value>[,<attribute name>=<value>...]

If white space occurs within the *additional attributes* argument, or the equal sign "=" occurs within a *value* string, it must be enclosed with single quotes or double quotes.

The following attributes can be set using the -W option only:

create_resv_from_job=<value>

When this job starts, immediately creates and confirms a *job-specific start reservation* on the same resources as the job (including resources inherited by the job), and places the job in the job-specific reservation queue. Sets the job's create_resv_from_job attribute to *True*. Sets the job-specific reservation's reserve_job attribute to the ID of the job from which the reservation was created. The new reservation's duration and start time are the same as the job's walltime and start time. If the job is peer scheduled, the job-specific reservation is created in the pulling complex.

Format: Boolean

Example:

```
simsh <path to snapshot> qsub -Wcreate_resv_from_job=1 myscript.sh
```

Cannot be used with job arrays or jobs being submitted into a reservation.

group_list=<group list>

List of group names. Job is run under a group name from this list. Sets job's group_list attribute to *group list*.

Only one group name may be specified without a hostname. Only one group name may be specified per named host. The server on which the job resides will select first the group name whose hostname is the same as the server name. Failing that, the next selection is the group name with no specified hostname. The group names on the server and execution hosts must be the same. The job submitter's primary group is automatically added to the list.

Under Windows, the primary group is the first group found for the user by PBS when it queries the accounts database.

Format of *group list*: *<group name>[@<hostname>][,<group name>@<hostname> ...]*

Default: Login group name of job owner

pwd

pwd=''

pwd=""

These forms prompt the user for a password. A space between W and pwd is optional. Spaces between the quotes are optional. Examples:

```
simsh <path to snapshot> qsub ...  -Wpwd <return>

simsh <path to snapshot> qsub ...  -W pwd='' <return>

simsh <path to snapshot> qsub ...  -W pwd=" " <return>
```

Available on supported Linux platforms only.

release_nodes_on_stageout=<value>

When set to *True*, all of the job's vnodes not on the primary execution host are released when stageout begins.

Cannot be used with vnodes tied to Cray X* series systems.

When cgroups is enabled and this is used with some but not all vnodes from one MoM, resources on those vnodes that are part of a cgroup are not released until the entire cgroup is released.

The job's stageout attribute must be set for the release_nodes_on_stageout attribute to take effect.

Format: *Boolean*

Default: *False*

run_count=<value>
Sets the number of times the server thinks it has run the job. Sets the value of the job's run_count attribute to *value*.

Format: Integer greater than or equal to zero

sandbox=<sandbox spec>
Determines which directory PBS uses for the job's staging and execution. Sets job's sandbox attribute to the value of *sandbox spec*.

Allowed values for *sandbox spec*:

PRIVATE
PBS creates a job-specific directory for staging and execution.

HOME or unset
PBS uses the user's home directory for staging and execution.

Format: *String*

stagein=<path list>
stageout=<path list>
Specifies files or directories to be staged in before execution or staged out after execution is complete. Sets the job's stagein and stageout attributes to the specified *path list*s. On completion of the job, all staged-in and staged-out files and directories are removed from the execution host(s). The *path list* has the form:

<file spec>[,<file spec>]

where *<file spec>* is

<execution path>@<hostname>:<storage path>

regardless of the direction of the copy. The name *execution path* is the name of the file or directory on the primary execution host. It can be relative to the staging and execution directory on the execution host, or it can be an absolute path.

The "@" character separates *execution path* from *storage path*.

The name *storage path* is the path on *hostname*. The name can be relative to the staging and execution directory on the primary execution host, or it can be an absolute path.

If *path list* has more than one *file spec*, i.e. it contains commas, it must be enclosed in double quotes.

If you use a UNC path, the *hostname* is optional. If you use a non-UNC path, the *hostname* is required.

umask=<mask value>
The umask with which the job is started. Sets job's mask attribute to *mask value*. Controls umask of job's standard output and standard error.

The following example allows group and world read of the job's output and error:

```
-W umask=33
```

Format: one to four digits; typically two

Default: *system default*

-z
Job identifier is not written to standard output.

--version
The qsub command returns its PBS version information and exits. This option can only be used alone.

3.14.4 Operands

The qsub command accepts as operands one of the following:

(no operands)

Same as with a dash. Any PBS directives and user tasks are read from the command line.

<script>

Path to script. Can be absolute or relative to current directory where `qsub` is run.

-

When you use a dash, any PBS directives and user tasks are read from the command line.

-- <executable> [<arguments to executable>]

A single executable (preceded by two dashes) and its arguments

The executable, and any arguments to the executable, are given on the `qsub` command line. The executable is preceded by two dashes, "--".

If a script or executable is specified, it must be the last argument to `qsub`. The arguments to an executable must follow the name of the executable.

When you run `qsub` this way, it runs the executable directly. It does not start a shell, so no shell initialization scripts are run, and execution paths and other environment variables are not set. You should make sure that environment variables are set correctly.

3.14.5 Standard Output

Job ID for submitted job

If the job is successfully created

(No output)

If the `-z` option is set

3.14.6 Standard Error

The `qsub` command writes a diagnostic message to standard error for each error occurrence.

3.14.7 Exit Status

For non-blocking jobs:

Zero

Upon successful processing of input

Greater than zero

Upon failure of `qsub`

For blocking jobs:

Exit value of job

When job runs successfully

3

If the job is deleted without being run

3.14.7.1 Warning About Exit Status with `csh`

If a job is run in `csh` and a `.logout` file exists in the home directory in which the job executes, the exit status of the job is that of the `.logout` script, not the job script. This may impact any inter-job dependencies.

3.14.8 See Also

"Submitting a PBS Job", on page 11 of the PBS Professional User's Guide, "Job Attributes" on page 327, "Resources Built Into PBS" on page 265, and "Requesting Resources", on page 53 of the PBS Professional User's Guide.

3.15 sim

Simulates behavior of workload at a PBS complex

3.15.1 Synopsis

sim [-h] [-l] [-L] [--monitor=<duration>] [-n <cycles> | -t <duration>] [-o <output path>] [-O <0 | 1>]

sim --version

3.15.2 Description

Simulate all of the behavior of the workload at a PBS complex except for hooks. In simulation, the default scheduler runs jobs, writes log files, etc. You can find out how your workload will behave in the next days, weeks, or months by running a simulation that takes only a short amount of actual time.

By default, each simulation runs until all runnable jobs have been run. If there are jobs that can never run, they remain queued after a simulation finishes.

3.15.2.1 Caveats

- This command runs only default scheduler; it does not run multischeds.
- This command ignores job environment variables: it does not use the value of the job's Variable_List attribute.
- Hooks do not run in simulations. For example, queuejob hooks do not run, so jobs that were queued before you take a snapshot have already been modified by any queuejob hooks, but if you submit new jobs in the simulation, those modifications will not happen. To emulate the behavior of hooks inside the sandbox, you can submit jobs as they would be after hooks have modified them.
- This command does not run job executables.

3.15.2.2 Options to the sim Command

-h, --help
: Display this help message

-l
: (Lowercase L) Generate simulation log

-L
: Write scheduling logs to the `sched_logs` directory in the snapshot

--monitor=<duration>
: Update the snapshot after every period specified by *duration*

-n <cycles>
: Number of scheduling cycles to run. When used with the `-t <duration>` option, simulation runs for the shorter time. For example, if you specify "-t 600 -n 2" and it only takes 30 seconds to run two scheduling cycles, the simulation ends after 30 seconds.

  Cannot be used with the `-t` option.

-o <output path>
: Path to output snapshot.

  Default: <path to input snapshot>_out

--O <0 | 1>

Turn optimizations off or on

Default: on

-t <duration>

Time in seconds to to run simulated universe. Actual time required is much shorter. When used with the `-n <cycles>` option, simulation runs for the shorter time. For example, if you specify "-t 600 -n 2" and it only takes 30 seconds to run two scheduling cycles, the simulation ends after 30 seconds.

Default: simulation runs until all runnable jobs are finished. Any jobs that can never run remain queued.

Cannot be used with the `-n` option.

--version

This command returns its version information and exits. This option can only be used alone.

3.15.3 Output of sim Command

Each simulation creates an output snapshot directory, and writes output statistics to the screen.

3.15.3.1 Simulation Output Snapshot Name

3.15.3.1.i Initial Output Snapshot Name

By default, the name of the simulation output snapshot is the name of the input snapshot with "_out" appended.

For example, running a simulation on the snapshot named "Snap1" produces the result snapshot named "Snap1_out".

You can specify the name of the output snapshot:

simsh <input snapshot> sim -o <output snapshot name>

For example, if your input snapshot is named "Snap1_new", and you want the output snapshot to be named "Snap1_test1":

```
simsh Snap1_new sim -o Snap1_test1
```

3.15.3.1.ii Naming for Multiple Output Snapshots

Each time you run a simulation without specifying a name for the output snapshot, Simulate names the output snapshot with the input snapshot name and appends "_out". If a snapshot with that name already exists, Simulate renames it by appending "_out". For example, if you run a simulation on a snapshot named "Snap1", you get an output snapshot named "Snap1_out". If you run another simulation on "Snap1", you get a new output snapshot named "Snap1_out", and the old "Snap1_out" is renamed "Snap1_out_out".

3.15.3.2 Simulation Output Contents

Running the `sim` command with no options creates a snapshot containing accounting log files. If you use the `-L` option, the snapshot also contains scheduler log files.

3.15.3.3 Simulation Output Statistics

When you run a simulation, Simulate prints statistics showing how the workload ran through:

- Number of scheduling cycles run: <integer>
- Number of jobs submitted <integer>
- Number of jobs run: <integer>
- Number of jobs left over: <integer>

These are the jobs which could not be run because the job requested an unavailable queue or resource, the job exceeded a limit, etc.

- Time taken to simulate: <seconds>

3.16 tracejob

Extracts and prints log messages for a PBS job

3.16.1 Synopsis

tracejob [-a] [-c <count>] [-f <filter>] [-l] [-m] [-n <days>] [-p <path>] [-s] [-v] [-w <cols>] [-z] <job ID>

tracejob --version

3.16.2 Description

The `tracejob` command extracts log messages for a given *job ID* and prints them in chronological order.

The `tracejob` command extracts information from server, default scheduler, accounting, and MoM logs. Server logs contain information such as when a job was queued or modified. Scheduler logs contain clues as to why a job is not running. Accounting logs contain accounting records for when a job was queued, started, ended, or deleted. MoM logs contain information about what happened to a job while it was running.

To get MoM log messages for a job, `tracejob` must be run on the machine on which the job ran. If the job ran on multiple hosts, you must run `tracejob` on each of those hosts.

Some log messages appear many times. In order to make the output of `tracejob` more readable, messages that appear over a certain number of times (see option `-c` below) are restricted to only the most recent message.

3.16.3 Using tracejob on Job Arrays

If `tracejob` is run on a job array, the information returned is about the job array itself, and not its subjobs. Job arrays do not have associated MoM log messages. If `tracejob` is run on a subjob, the same types of log messages are available as for a job. Certain log messages that occur for a regular job will not occur for a subjob.

3.16.4 Required Privilege

All users have access to server, scheduler, and MoM information. Only Administrator or root can access accounting information.

3.16.5 Options to tracejob

-a

Do not report accounting information.

-c <count>

Set excessive message limit to *count*. If a message is logged at least *count* times, only the most recent message is printed.

The default for *count* is 15.

-f <filter>

Do not include log events of type *filter*. The `-f` option can be used more than once on the command line. The following table shows each filter with its hex value and category:

Table 3-28: tracejob Filters

Filter	Hex Value	Message Category
error	*0x0001*	Internal errors
system	*0x0002*	System errors
admin	*0x0004*	Administrative events
job	*0x0008*	Job-related events
job_usage	*0x0010*	Job accounting info
security	*0x0020*	Security violations
sched	*0x0040*	Scheduler events
debug	*0x0080*	Common debug messages
debug2	*0x0100*	Uncommon debug messages
resv	*0x0200*	Reservation debug messages
debug3	*0x0400*	Less common than *debug2*
debug4	*0x0800*	Less common than *debug3*

-l

Do not report scheduler information.

-m

Do not report MoM information.

-n <days>

Report information from up to *days* days in the past.

Default number of days: *1* = today

-p <path>

Use *path* as path to `PBS_HOME` on machine being queried.

-s

Do not report server information.

-w <cols>

Width of current terminal. If *cols* is not specified, `tracejob` queries OS to get terminal width. If OS doesn't return anything, defaults to *80*.

-v

Verbose. Report more of `tracejob`'s errors than default.

-z

Suppresses printing of duplicate messages.

--version

The `tracejob` command returns its PBS version information and exits. This option can only be used alone.

3.16.6 Operands

The `tracejob` command accepts one *job ID* operand.

For a job, this has the form:

<sequence number>[.<server name>][@<server name>]

For a job array, the form is:

<sequence number>[][.<server name>][@<server name>]

For a subjob, the form is:

<sequence number>[<index>][.<server name>][@<server name>]

Note that some shells require that you enclose a job array identifier in double quotes.

3.16.7 Exit Status

Zero
: Upon successful processing of all options

Greater than zero
: If `tracejob` is unable to process any options

3.16.9 Caveats

Do not try to use the -p option. This causes the command to look some place other than the snapshot, and the command returns an error.
